author has compared the curative action of quinin with that of other drugs in the treatment of the disease, and quinin makes the best showing of any of the drugs used. It requires a fewer number of administrations of quinin to cure the disease and the number of failures from its use was the smallest. The drug should be given by the mouth at first and, if this method is not productive of good results in a few days, it should also be given by the rectum in 20-grain doses. In 1894 Buchanan tried the experiment of giving daily or several times a week a dose of quinin or of cinchonidin to every prisoner in the Punjab. The sickness and mortality rates in this district for that year were so low that the system was tried in other provinces, so for the past 5 years the prophylactic use of quinin against malaria has been tried on an extensive scale. As a result it is safe to state that quinin will prevent the incidence of malaria to a considerable degree. Furthermore, the prolonged use of quinin by healthy individuals is possible without the slightest mischief resulting. The author has never seen a single case of hemoglobinuria resulting from the use of the drug. Fielding-Ould entirely disagrees with the idea that quinin should be used as a prophylactic against malaria. It is obviously wrong to speak of the prophylactic effect of quinin; the alkaloids of cinchona do not prevent malaria, they only attack the parasites when they are in a certain stage of their development. A patient has not always young amebas in his blood, yet he continues to take large doses of quinin, thereby often doing great damage to his digestion, that function which it is most important to keep in good order in the tropics. In addition to disturbing the peptic digestion, quinin is very apt to lead to congestion and torpidity of the liver, and it is the patients who exhibit hepatic symptoms who go down, when invaded by malaria parasites, with pernicious forms of the disease. Except in cases of actual fever and on exceptional occasions, such as after great fatigue or during a march, quinin should be avoided. A full dose of 15 grains of quinin should be given when the organisms are about to sporulate or when they are in their youngest phase as sporocytes. So long as digestive disturbance is absent the drug should be given by the mouth, but when the stomach is intolerant the hypodermic should be employed; 3 grains of the hydrochlorate is a full dose by this latter route. If given with proper aseptic precautions suppuration seldom occurs. Rectal administration is often advantageous and as much as 30 or 40 grains may be given at one dose. The administration of quinin should be continued for some weeks after the cessation of all febrile symptoms or until the microscope shows that the blood is free from the parasites. Manson said that the reputed prophylactic action of quinin is but a phase of its therapeutic action; it is the application of the drug to the parasite and not an immunizing of the body against the entrance of the parasite that we have to deal with; therefore, we may confidently expect that if it will cure a malarial infection it will prevent its development,—the development of, though not the introduction of, the germ. We may expect it to be a timely prophylactic against the benign tertian form of the organism but less active against the malignant tertian form. The value of the drug is likely to be underestimated in consequence of its being given in a routine fashion, and often under conditions in which it cannot be absorbed. Marsden has given quinin both as a prophylactic and as a therapeutic agent for 20 years with uniformly good results. Rees is of opinion that 5-grain doses of quinin administered daily lessen the severity of the cases of fever and diminish the mortality, although it does not reduce the number of cases that develop. He inclines to the use of 2-grain doses of quinin 3 times a day as a prophylactic. Harford-Battersby believes strongly in the prophylactic action of quinin. For the curative effect, he believes that the best results are obtained by giving 10 grains of the drug at the beginning of the sweating stage, after the bowels have been freely opened. He does not believe that quinin is the cause of hemoglobinuric fever. Wilson does not think that quinin has much prophylactic effect. Maitland had used methyl-blue with good results in cases of malaria, in doses of 3 grains 3 times a day. He had found that quinin could be given with safety in any stage of pregnancy. Henderson gives a dose of 15 grains of quinin in the sweating stage of the disease, after the temperature has fallen; he follows this with a few 5-grain doses and this usually puts an end to the attack. He considers quinin a dangerous drug to give to pregnant

women, and is of opinion that the effect of quinin on the pregnant woman can be lessened by guarding it with some preparation of opium or with chlorodyne. Ross pointed out that old cases of malaria might be secondary to enlargement of the liver and the spleen, not due to the parasites and not amenable to quinin. He prefers to give quinin in solution. Baker believes that the prophylactic dose of quinin is the same as the curative dose. [J.M.S.]

2.—James has succeeded in keeping members of the *Anopheles* genus of mosquito alive for 14 or 15 days by putting them in a bottle in which a ripe banana was hung during the day and liberating them beneath his own mosquito-bar during the night. By this method the author has traced the **metamorphosis of the *Filaria sanguinis hominis*** to its final stage in the *Anopheles Rossii*. The young filariae are found in the tissues of the thorax, in those of the head and neck, and, in smaller numbers, in those of the abdomen. By carefully dissecting the tissues of the head with needles and separating the parts of the proboscis, 2 or 3 filariae may almost invariably be found. On 2 occasions a filaria was found stretched out lengthwise, partly within the labrum of the proboscis, the remainder of the body being curled up in the tissues of the head. Since large, moving filariae have been found in this situation it can hardly be doubted that young filariae may gain entrance to the human host when the mosquito bearing them are in the act of biting. In the tissues of the mosquito the filariae can move about by boring their way from one place to another. In water, however, their powers of locomotion are very limited and they die in from 2 to 3 hours. The author succeeded in transferring a filaria that he was examining in water to another part of a microscopic slide; then, by introducing some human blood beneath the cover-glass, the movements of the worm were seen to become much more active. The filariae that were in water alone died in about 2½ hours, but the one that was kept in blood was active for over 6 hours. If this experiment can be confirmed it will afford a strong proof that the filaria pass directly from the mosquito to man without having first to exist for some time in water. In the discussion that followed the reading of the paper, Manson said the fact that the filaria has been found in the proboscis of the mosquito suggests, without absolutely proving, that the parasite is directly inoculated into man by the bite of the mosquito. It is a well-known fact that the young filaria can live several hours in water, and possibly it would live longer in dirty than in clean water, because more food would be found in the former. It must be remembered that before the embryos can be found in the blood a large number of parent worms must be present in the lymphatics. It is easy to understand how the European escapes infection by filaria, sleeping as he does under a mosquito bar and in good hygienic surroundings, he is at most bitten once or twice by filariated mosquitos. The native, on the other hand, sleeps without a net and is month after month bitten by his own filaria-charged mosquitos, and thus becomes the subject of a high-grade filarial infection. [J.M.S.]

3.—Maitland dissents from the theory of direct inoculation of the **filaria** from the mosquito to the human host. He calls attention to the fact that cases are on record in which servants suffering from **filariasis** live in the same house with masters who are not subjects of that disease. He does not think that the mosquito-bar explains the apparent immunity because the Europeans are liable to be bitten by mosquitos during the day. He believes that water is the medium by which the filaria is introduced into the human system, and he cites several instances of infection that would tend to confirm that opinion. He believes the immunity enjoyed by the European is due to the fact that only boiled or filtered water is drunk by this portion of the population. [J.M.S.]

4.—Buchanan describes the **hot weather diarrhea of India**. The onset of the disease is always sudden and is characterized by violent purging and vomiting. The stools are at first loose and feculent and the vomitus is composed of the last meal. The former soon become abundant, more or less colorless, and pour out from the rectum as from a tap. The patient becomes collapsed and cyanotic and resembles, though in a much less degree, the appearance of a cholera patient. The urine may be suppressed, and in old people the attack may result fatally in a short time.

Usually, the violence of the attack becomes less in the course of a day, the temperature rises to 102°, the stools become normal, and recovery is rapid. In some cases the inflammation of the intestine goes on to an ileocolitis and dysenteric symptoms persist for a few days. Transient albuminuria is often seen, constipation after recovery is the rule, and microscopic examination of the stools shows epithelium, starch grains, particles of grain and husk, and numerous bacteria. The treatment consists of liquid diet, brandy, or rum, and, after the stools become distinctly watery, chlorodyne or camphoridylne. A dose of castor oil is indicated when the diarrhea is about checked. The predisposing causes are: (1) Badly cooked food, (2) hastily eaten food or overeating, (3) unripe or overripe food, (4) raw grain, (5) drinking too much water, (6) too rich food, (7) badly prepared grain, (8) overindulgence in alcohol, and (9) excessive use of inferior fibrous vegetables. The disease is to be differentiated from cholera (1) by the absence of cholera in the neighborhood, (2) by the low death-rate, (3) by the absence of cramps, the less marked collapse, and the absence of rice-water stools. [J.M.S.]

5.—Duncan has found that **malarial fevers among the Goorkhas** are of a particularly intractable character. If the rectal injection of 15 or 20 grains of quinin was not beneficial the only resort left was to send the patient to another district. The rectal way was found more efficient for the administration of quinin than administration by the mouth. Cases of **tuberculosis of the lungs** pursued a very rapid course. **Mumps and measles** were very common. **Ophthalmia** was common and more so among the married Goorkhas than among the bachelors, probably on account of the more unsanitary condition of the quarters of the former class. **Typhoid fever** was not common. [J.M.S.]

6.—Giles gives a description of the method that he employed in order to develop adult members of **Ankylostoma duodenale** in the laboratory. He believes that the presence of the parasite in the human intestine is responsible for a formidable mortality, and even a greater amount of chronic sickness. The worm has been found in persons who are apparently healthy as well as in those manifestly sick. The **anemia** produced by the worm cannot be due to the loss of blood alone, but is very probably due to the damage to the mucous membrane of the intestines by the worms. It is also probable that the worm in its growth produces a poisonous excretion that is concerned in the production of the anemia. Fearnside has made a systematic search for the ova of *Ankylostoma duodenale* in the stools of all the new arrivals at the Central Prison, Rajahmundry. Out of 678 new arrivals, 68.1% harbored the parasite. Out of 72 persons that harbored the parasite 70% were in good health, 16.6% were in indifferent health, and 13.9% were in bad health. Nearly 35% of subjects harbor both *Ankylostoma duodenale* and *Ascaris lumbricoides* simultaneously. Out of 200 convicts that had been in the jail for over 6 months, and who were, consequently, subjected to better hygiene and cleaner food, only 53% harbored *Ankylostoma*, while only 18.5% showed *Ascaris lumbricoides*. Out of 105 postmortem examinations 74.3% showed the presence of this worm; 57.9% showed congested areas in the bowel; and 11.4% showed small erosions and ulcers. The experience of the author goes to show that the effects of the *Ankylostoma* are for the most part secondary. The worms seldom occur in such numbers as to cause true **ankylostomiasis**. The symptoms of **ankylostomiasis** are the result of concurrent disorders such as malaria and dysentery. In these conditions the presence of the parasite sets up local congestions and erosions of the bowel which cause a catarrh, which, in turn, retards the proper assimilation of the food and the recovery of the patient. Furthermore, the parasite bleeds a patient who cannot afford to lose more blood. For the **diagnosis of ankylostomiasis** it is necessary to exclude all other blood-destroying diseases rather than to depend upon the mere presence of the parasite in the bowel. Rogers defines the term **ankylostomiasis** as a disease characterized by anemia produced by long continued small losses of blood through the gastrointestinal mucous membrane, caused by the presence of several hundreds of *ankylostomata* acting for many months; or by a still larger number acting for a shorter time. Ova can easily be found in a single cover-glass preparation of the feces when but 5 to 15 worms are present; but, on the other hand, if they are met

with in nearly every field of the microscope, then it is certain that the parasites are present in large numbers and thymol is indicated if the patient is in a condition to stand it. The mere discovery of one or two ova is not an indication for thymol unless it is quite certain that the drug will do no harm; because much greater injury may be inflicted by the drug than will be compensated for by the removal of the very few worms that may be present. The author has made careful studies of the blood condition in ankylostomiasis and several other conditions that may be mistaken for it. He finds that in healthy Assamese the hemoglobin is 62%; the red corpuscles are 4,734,000; and the leukocytes are 7,325. In the epidemic malaria of Assam the hemoglobin is 33%; the red corpuscles number 2,462,000; the leukocytes were 2,600. In ordinary chronic malaria the hemoglobin was 32%; the red corpuscles were 2,000,000; the white corpuscles were 1,600. In ankylostomiasis the hemoglobin was 11.5%; the red corpuscles were 1,145,000; the leukocytes numbered 5,338. In cases of malaria complicated by ankylostomiasis the hemoglobin was 27%; the red cells were 3,120,000; the white corpuscles 3,200. The most important distinction is that in ankylostomiasis the hemoglobin is reduced twice as much as the number of red corpuscles so that the color index sinks to 0.31, or about $\frac{1}{3}$ the normal of healthy people of Assam. Again, the white corpuscles, although absolutely reduced in number, are relatively less reduced than are the reds, so that the proportion rises to 1 to 524 against 1 to 684 in the healthy controls. The color-index in uncomplicated cases of malarial anemia was always over 0.5; while the highest color-index encountered in ankylostomiasis was always under 0.4. The correct treatment of these 2 diametrically opposite forms of anemia should obviously be different. In that due to ankylostomiasis, iron is urgently indicated in order to assist in the production of hemoglobin; in the anemia of malaria, on the other hand, arsenic and bone-marrow are strongly indicated in order to increase the output of the red corpuscles which are being, or have been destroyed by the fever. Baker studied the prisoners in the Moulmein jail in order to determine the frequency of the occurrence of the ankylostoma in the natives of Burma. Taking the natives of Burma alone, of whom there were 69 studied, it was found that 55% were infected with ankylostomata. Ankylostomiasis is both directly and indirectly responsible for much mortality. The infection is conveyed through the medium of contaminated food, and water has but little to do with the matter. It would seem, therefore, that no marked diminution in the prevalence of and mortality from ankylostomiasis in Burma can be looked for until some system of sanitation has been generally adopted that will obviate the broadcast distribution of infective night-soil. Manson is of the opinion that thymol rarely fails in the treatment of ankylostomiasis, provided it is given in adequate and rapidly repeated doses, say 30 grains every hour for 4 doses. The differentiation of malaria from ankylostomiasis by hemocytometric methods, though interesting and valuable from a pathologic point of view, is impracticable under ordinary circumstances. [J.M.S.]

7.—After speaking of the conditions under which and the manner in which a **tropical abscess of the liver** may rupture into the thoracic cavity, Macleod points out that, in old-standing cases of lung-lesion consequent on hepatic abscess, the pathologic burden has been transferred from the abdomen to the chest, and that relief measures must be applied with that understanding, the lung-lesion being treated according to the special indications of the case, and the liver left to take care of itself. [J.M.S.]

8.—Cantlie says that by the term **subhepatic abscess** is meant a collection of pus on the under surface of the liver, between that organ and its capsule, commencing most probably in the lymphatics of this region. This form of hepatic abscess does not seem to depend upon dysentery or other forms of intestinal ulcer for its development, though it may be malarial. The only single definite feature which can serve as a guide to a diagnosis of these abscesses is the presence of a tumor in the epigastrium which is found to contain pus and is bounded by the liver above. The prognosis in these cases is generally good and the treatment consists in tapping with a large trocar and draining through a large tube. [G.B.W.]

9.—Smith says that **liver abscess** should always be put under the care of a surgeon, as this condition has little chance of recovering spontaneously, and the need of surgical

interference is often called for purely to help in the diagnosis either by puncture or exploratory laparotomy. In very few cases is it possible to make a positive diagnosis of pus in the liver by clinical methods alone. For diagnostic purposes the simplicity of puncture with a proper and sterilized needle is superior to the discomforts of an exploratory opening of the abdominal cavity. As to operation for the evacuation of the abscess a great deal of care is necessary in order to avoid infecting either the pleural or peritoneal cavities. In the transpleural route it is generally advisable, especially where a mixed infection of the abscess itself is suspected, to leave packing in the wound for a few days before opening the abscess, so that adhesions may form and shut off the dangerous cavities. [G.B.W.]

10.—Bassett-Smith reports a case of **abscess of the left lobe of the liver** occurring in a man who had just recovered from a subacute attack of dysentery. Two years previously he had returned from the Mediterranean, where he had been for a long while, but had always been perfectly well during his residence there. The abscess pointed in the epigastrium and was opened, but the patient died 3 days later. The postmortem showed the left lobe of the liver to be entirely occupied by a large accumulation of pus surrounded by necrotic walls. There were no secondary abscesses in the liver, though the organ was markedly increased in size. Cultures from the pus showed the presence of large numbers of *Amoebae coli*. [G.B.W.]

11.—Ross suggests some **improvements in medical organization in the tropics**, improvements that have long been required, and that can be very easily made. Instruction in animal parasitology and in tropic medicine should be given. Every examination-paper on pathology and medicine should contain at least one question on animal parasitology, and one on tropic medicine. Small but up-to-date libraries should exist in all the leading towns in the tropical possessions, especially in connection with the principal government-hospitals. Microscopes, with oil-immersion lenses, antitoxins, antivenene, and apparatus for bacteriologic diagnosis, such as material for the Widal test, should be found in the principal towns. Medical regulations and municipal sanitary regulations should be compiled and issued with the greatest care. Research should be organized (1) by the foundation of research laboratories; (2) by the appointment of specialists to prosecute certain definite lines of investigation, and (3) by the encouragement of private research. There should be a central scientific authority. [J.M.S.]

12.—Thin reports the case of J. R., aged 27, a marine engineer, who had been in British Central Africa for 18 months, and who died of **blackwater fever**. White corpuscles containing malarial pigment in minute granules and very small spheres were found in the tissues of the spleen. They were comparatively most numerous in the malpighian bodies and were present in the large white corpuscles of the splenic pulp. They were also found in the white corpuscles lying external to the walls of the small veins and in the lumen of the veins. In the liver, white corpuscles containing pigment were found in the capillaries and in small numbers in the veins. Most of the pigment was found in the endothelium of the capillaries, the course of many of these vessels being marked out by the pigment accumulated in the swollen and degenerated endothelial cells. Occasionally, small particles of pigment were found between the capillary vessels and the contiguous liver cells. In many of the liver cells the pigment was found in minute granules in the substance of the cells. In the kidney, the epithelial cells first become swollen and granular, then are detached from the basement membrane and block the tubule; the epithelial blocks gradually disintegrate until the final stage is reached, when the lumen of the tubule is found with a mass of minute rounded granules, not unlike groups of large cocci. The changes in the epithelial cells of the kidney illustrate the very powerful effect, in these cases of blackwater fever, of a toxin generated by the parasite. In the discussion that followed the reading of the paper, Manson said he would protest against jumping at the conclusion that **hemoglobinuric fever** is a form of malaria merely on the strength of the discovery of the malarial parasite in the hemoglobinuric patient's blood, or of melanin in his viscera. [J.M.S.]

13.—The **sphalangi** of Cyprus is an insect that resembles the ant in general appearance and in size. Williamson

has seen several cases in which the bite of this insect has been followed by symptoms that resemble **anthrax**. He thinks that the anthrax infection is conveyed to the patient by the short hairs with which the insect is covered; the insect, in turn, getting the anthrax-bacilli from feeding on the carcasses of animals that have died of anthrax, or, as it is called in Cyprus, *philangari*. [J.M.S.]

14.—In the section of Tropical Diseases of the British Medical Association, Hutchinson opened a discussion on **yaws**. He presented to the section a young man who was said to be the subject of yaws. The author expressed his firm conviction that yaws was syphilis modified by race and climate. He considered that syphilis found its way to England, not from America, but from the African coast. Davies said that he had seen yaws in Fiji and in Samoa, but that it had always occurred in children. Manson said that inoculation by yaws would not protect against syphilis nor *vice versa*, and that it would be strange, if the two diseases were identical, that this should be so. Yaws, like many other parasitic diseases peculiar to the tropics, could not be imported to colder climates owing to the death of the parasite on account of the absence of continued high temperature. MacLeod said the patient exhibited by Hutchinson was undoubtedly infected with syphilis and not with yaws. [J.M.S.]

15.—According to Tirard, **bronchopneumonia** is frequent among children under 2 or 3 years of age. After this age, however, the tendency to assume the adult type of **pneumonia** is greater and a large proportion of patients admitted to the wards present the physical signs of true **croupous pneumonia**. Pneumonia is no doubt the result of a general infection. The author is extremely doubtful whether the disease is ever contagious in the ordinary sense of the term. Pneumonia may present abnormal features, (1) in regard to the temperature, (2) in regard to the initial symptoms, and (3) in regard to the physical signs. Nicholson has studied the cases of pneumonia by means of the sphygmograph and the sphygmometer. In acute croupous pneumonia at the onset and for the first 48 hours or so the pulse is very generally of higher tension than normal. After 2 or 3 days, when the disease is working toward the crisis, the pulse-curve becomes of the low-tension type. The tracing becomes markedly irregular and unequal in the force of the individual beats. In the bronchopneumonia of children the same characteristics of pulse and blood-pressure were found; but the pressure was never so high as at the commencement of the attack. The chief indication for treatment suggested by the condition of the pulse seems to be that the arterial pressure should be looked after. Its tendency to fall should be anticipated and all therapeutic measures should aim at maintaining a pressure sufficient to give the cardiac muscle an adequate blood-supply through the coronary arteries to enable it to hold out. The newer methods of treatment by abdominal ice bag and by saline infusions fulfil this indication. Of drugs used to maintain a good blood-pressure, digitalis, though theoretically ideal, is peculiarly disappointing in children, and strophanthus, strychnin, and ammonium carbonate are much more useful. Gossage said that in bronchopneumonia the infection comes through the bronchial tubes, while in lobar pneumonia it comes by the blood-paths. [J.M.S.]

16.—Fenwick reports the case of a male child, 1 year and 5 months old, who suffered from swelling of the abdomen and constipation. The latter symptom gradually increased until the age of 9 months, when the abdomen began to swell. The abdomen was enormously distended and almost globular in shape. From time to time, strong peristaltic contractions were observed and it then became obvious that a prominence seen above the umbilicus was due to a single piece of bowel, which came into relief like a man's arm slightly bent at the elbow, and slowly contracting from right to left. The lower left half of the belly appeared, at the same time, to contain 2 perpendicular cylinders that moved in opposite directions. At the autopsy, when the belly was opened, its contents appeared to consist of 3 distended pieces of intestine. Its right half was occupied by the transverse colon, which passed from the right iliac fossa, obliquely upward and to the left, toward the hypochondrium, filling up the epigastrium and giving rise to the protuberance observed there during life. The left half of the abdominal cavity contained 2 sacs that lay side by side in its long axis and reached from above the

level of the umbilicus to the brim of the pelvis. Subsequent examination showed that this latter appearance was due to an enormous dilation of the sigmoid flexure while the pelvis was completely filled by the distended rectum. These cases of **dilation of the colon** have as their most important and significant feature a **hypertrophied state of the muscular wall of the bowel**. [J.M.S.]

17.—West opened the discussion on **enlargement of the spleen in children** at the meeting of the Section of Diseases of Children of the British Medical Association. He laid particular emphasis on **splenic anemia** or **primitive splenomegaly**. The features of the disease in the adult are extreme and progressive anemia, usually without emaciation; early and progressive enlargement of the spleen, without enlargement of the lymphatic glands; attacks of severe pain in the splenic region; and a fatal ending sooner or later with the usual symptoms, namely, profound anemia, repeated hemorrhage, and extreme asthenia. The affection in the infant runs a chronic course, lasting some months, but in the end many cases get quite well. Syphilis is occasionally, and rickets frequently, associated with splenic anemia; but the association is not constant in either case. Neither syphilis nor rickets can be the sole cause, and are probably not the cause at all, except, perhaps, indirectly by means of the ill-health to which either leads. [J.M.S.]

18.—Nicoll reports a case of **congenital stenosis of the pylorus** successfully treated by operation. The patient when first seen was 5 weeks old, and vomited all food as soon as swallowed, the vomited milk being partially clotted, but showing no further alteration. The child became greatly emaciated, so that at the age of 6 weeks a laparotomy was performed. "The pylorus was found represented by a bulky ring of muscular (or fibromyomatous) tissue." The operation carried out was practically a Loretta's, consisting in opening the stomach and forcibly dilating the stenosed pylorus. The child recovered perfectly from the operation, and 12½ months afterwards, except for a slight degree of rickets, was in perfect health. [G.B.W.]

19.—It seems to be generally admitted that **infantile scurvy** is caused by some deficiency in the diet of the patient. The defaulting factor, according to Colette, is none other than citric acid. Citric acid is a normal constituent of fresh milk. Henkel, working in Soxhlet's laboratory, found that milk contained 0.9 to 1.0 gram of citric acid per liter ($\frac{1}{2}$ gr. per ounce); and Göldner found that the citric acid was present as a calcium salt. Calcium citrate is at best only sparingly soluble in water, but it is markedly more soluble in cold than in boiling water. Now, since the sterilization of milk involves boiling, it is easily seen how the restriction of the diet of a child to sterilized milk may cause a deficiency in the supply of citric acid. Infantile scurvy, though apt to arise in children fed largely on sterilized milk, does not occur in those who have been fed on pasteurized milk. In the process of pasteurizing, the temperature reached is comparatively low, and the solvent power of the milk proportionately less interfered with. In order to prevent the occurrence of scurvy in milk-fed infants there is, first of all, the expedient of giving a sufficient allowance of fresh milk. If there is any reason for not giving fresh milk, pasteurized milk, prepared in the way described, may be used. If it is impossible to give a child anything but boiled milk we could get over the difficulty by the contemporaneous administration of lime juice (50 to 60 grs.) or of a citrate salt. The following precautions seem the most rational means of diminishing, as far as possible, the loss of citric acid in boiled milk: Any water used as a diluent to the milk should be added before the boiling, thereby making the fresh mixture a less concentrated solution of citrate than the undiluted milk, and, therefore, probably, less likely to suffer loss of the salt by its comparative insolubility on boiling and thereafter. Further, the milk should not be boiled a moment longer than the occasion requires, so as to minimize the formation of the more insoluble crystallizable citrate. Also, the milk should not be poured off when hot, but should be allowed to cool in the vessel in which it was boiled, and be well stirred when cool enough, in order to redissolve the citrate as far as possible. [J.M.S.]

20.—In this discussion on **scoliosis, flatfoot, and knockknee**, these deformities were treated from every standpoint. Clarke says that he believes that pathologic lesions are responsible to a very great extent for the devel-

opment of these deformities and quotes a number of cases from his own experience to substantiate this idea. Smith believes that scoliosis is due to pathologic changes in the vertebrae, consisting of a softening of the bones of the spine and a laxity of the ligaments. Williams reported the results of an analysis of 500 cases of spinal curvature. [G.B.W.]

22.—Little has analyzed all cases of **infantile paralysis** that have been under his observation during the last 3 years. Out of 147 deformities, in 115 patients, only 4 affected the upper extremity. The incidence in the sexes is nearly equal, girls being slightly more liable. Scoliosis was recorded in 4 cases and lordosis in 2. The 2 tibial muscles, and especially the tibialis anticus, are especially vulnerable. Next to them in order of frequency come the extensors of the toes (dorsiflexors of the ankle) and then the calf-muscles and flexors of the toes (plantar flexors of the ankle). In the upper part of the lower limb the quadriceps extensor is specially vulnerable. Tendon-transplantation or tenoplasty was performed 8 times and arthrodesis 5 times. [J.M.S.]

23.—Haworth reports the case of a girl, aged 16, who presented a slight **goiter**. The patient was put on 5-grain tablets of thyroïdin, 3 times daily, making a dose of 15 grains in the 24 hours. After taking the remedy for 3 weeks, the patient became sleepy, the least exertion induced copious perspiration, and the memory became fickle. The bowels were normal, and the appetite good, but she ate only because she was told to do so. She would do any kind of housework when requested. Though usually fond of reading, she complained that it made her head ache; sight and hearing were normal; she complained of frontal headache, and was glad to go to bed whenever her parents would let her. [J.M.S.]

24.—Morton reports a case of **puerperal septicemia** successfully treated with antistreptococcus serum, which he began to administer on the twelfth day. He is convinced the serum saved the life of the patient, a healthy, young primipara, and his only regret is that he did not resort to it sooner. [W.K.]

25.—Gray has found specimens of the **anopheles** mosquito on the island of **St. Lucia**. [J.M.S.]

26.—Harland reports 2 cases in which private soldiers developed **ophthalmic goiter** suddenly after being in action. One patient was 29, and the other 30. In the case of the second patient it was learned that his mother had been operated on for goiter. [J.M.S.]

27.—In this case of **renal calculus** the stone was found and removed, though the operation was difficult and tedious. Later the same patient had a small stone removed from his bladder by crushing, and at another time a third stone was removed from the prostatic urethra by an external incision. The patient finally made a good recovery. [G.B.W.]

1. The Treatment of Tuberculous and Purulent Joints with Large Glass Speculum Drainage and Pure Carbolic Acid, with a Report of Seventy Cases. A. M. PHELPS.
2. Generalized Tuberculous Lymphadenitis, with the Clinical and Anatomical Picture of Pseudoleukemia; The Study of a Case. THOMAS R. CROWDER.
3. A Consideration of the Statistics of Operations for the Relief of Malignant Disease of the Larynx. D. BRYSON DELAVAN.
4. Were These Unusual Cases of Partial Paralysis of the Vocal Bands Caused by Overuse of the Telephone? CLARENCE C. RICE.
5. The Lingual Tonsil. ROBERT LEVY.

1.—The method of applying **pure carbolic acid** to **joint-abscesses** is as follows: The abscess cavity is laid open. The opening into the capsule is found and enlarged and the joint explored. If there is extensive bone-disease

the opening is enlarged and after thorough curetment the joint is irrigated with a 1:1000 bichlorid solution. The joint is now filled with pure carbolic acid. It is allowed to remain 1 minute by the watch, after which the joint is thoroughly washed out with pure alcohol, and finally the alcohol is washed away with a 2% solution of carbolic acid. A large glass drainage-tube is then placed in the wound, reaching just flush with the surface. The tube for adults should be about 2 inches in diameter and 5 inches long; for children, 1 or 1½ inches in diameter and 3 inches long. To facilitate drainage packing may be loosely applied through the tube. Phelps says that the results obtained by this method of treating joint-abscesses are most satisfactory. [C.H.W.]

2.—Crowder reports the case of a lumberman of 34, who complained of gradual painful enlargement of the cervical and axillary lymph nodes, accompanied by loss of weight and by fever; the clinical picture of **pseudoleukemia**. The disease terminated in about 1 year and 8 months, with profuse diarrhea, high temperature, and delirium. About one week before death examination of the blood showed a specific gravity of 1.052; hemoglobin, 72%; red corpuscles, 4,320,000; leukocytes, 19,000. A differential count of the leukocytes showed small mononuclears, 30%; large mononuclears, 2.5%; polymorphonuclear neutrophils, 67%; eosinophiles, 0.5%. There were no myelocytes, no nucleated red cells, no polychromatism, and but slight poikilocytoses. Fowler's solution and Coley's toxins constituted the treatment. At autopsy, the cervical, submaxillary, axillary, mediastinal, parabronchial, and retroperitoneal lymph-nodes were found enlarged. There were also lymphoid nodules in the liver, spleen, and lung. There were secondary anatomic changes of less interest. Histologic examination of the lymphoid tissues showed the same conditions in all regions. The capsule was moderately thickened. The vessels were packed with red corpuscles. There was no line of demarkation between the cortex and the medulla of the lymph-nodes and the fibrous stroma was greatly increased. The structures were composed of lymphocytes, polymorphonuclear leukocytes, plasma cells, giant cells. Staphylococcus pyogenes albus and aureus were found in the peritoneal fluid and the former organism alone was found in the lung. Tubercle-bacilli were found in the cervical, retroperitoneal, and axillary lymph-nodes; in the lymphoid nodules in the liver, in the spleen, in the lymphoid nodules of the lung, and in subserous tubercles in the small intestine. Fragments of the lymph-nodes inserted into the peritoneal cavities of guinea-pigs killed the animals without producing general tuberculosis. [J.M.S.]

3.—Delavan says that as yet there are no satisfactory statistics of **operations on the larynx for malignant disease**. This is chiefly because the operator generally tries to keep his failures quiet and only publishes those cases which have been attended with more or less success; also the patients operated upon by careful observers have not been numerous enough to point to any conclusions. The statistics, however, which do exist show that those cases which die directly as the result of the operation grow distinctly less as the skill of the operator grows greater, and also that up to the present time there has been no case reported (as far as the author knows), either in this country or abroad, where the patient has recovered. Delavan believes that according to our present knowledge, major operations on the larynx for the removal of malignant disease have not furnished very marked evidence of success, though better statistics may in the future throw more light on this subject. [G.B.W.]

4.—Rice reports the cases of 2 men—one of 45 and the other of 55—who complained of **difficult phonation**. The former patient was under weight and very nervous; the latter was over-stout and in fair general condition. In the younger man the vocal cords had lost their ability to straighten out and come in contact for ¾ of their entire length and, though they could be approximated, they could not be maintained in that position. In the older patient the right vocal cord showed only fair adduction and a lack of tension. Consequently, the voice was husky. The author believes that in both cases the trouble was due to excessive and faulty use of the telephone. [J.M.S.]

5.—The symptoms which result from **enlargement of the lingual tonsil** are always more pronounced in neurotic and hysterical patients, but they, nevertheless, require

local treatment, as shown by the immediate relief following, in some very distressing cases, the application of the galvanocautery. The symptoms are somewhat varied, and may be divided into the following classes: 1. Those of simple discomfort, feeling of a foreign body in the throat, etc. 2. Those of severe cough. 3. Those of vocal distress. 4. Those of respiratory distress. 5. Those of distress in swallowing. 6. Hemorrhagic cases. The treatment of these cases should consist in general medication as well as local applications. The local treatment par excellence is the application of the galvanocautery. [G.B.W.]

Medical Record.

September 15, 1900. [Vol. 58, No. 11.]

- 1. Poisonous Snakes and Snake Poison. GUSTAV LANOMANN.
- 2. A Few Cases of Erosions of the Stomach. EDWARD QUINTARD.
- 3. The Radical Treatment of Tuberculosis of the Testis. ALEXIS V. MOSCHCOWITZ.
- 4. A Clinical Study of the Liver as a Factor in Elimination, and in the Production of Nephritis. GEORGE E. DAVIS.

1.—Langmann states that the venom glands which secrete the poison of snakes correspond to the parotids; the secretion is viscid, acid, straw, greenish-yellow, or orange in color, specific gravity 1.030 to 1.077, has a characteristic odor, and contains 12 to 67% of solids; the microscope shows a few epithelial cells, amorphous albuminoid masses, and no bacteria. The poisonous principle consists of two albuminoids which he calls venom-peptone and venom-globulin, the proportions of these differing in the different snakes. Peptones exert their actions mainly on the nervous system, the effects resembling in type those of acute bulbar paralysis or acute ascending spinal paralysis. Respiratory paralysis is a very common symptom. Globulins cause local reaction with hemorrhages there and elsewhere in the body, and destruction of blood-coagulability. Similarly with other toxins the poison causes fatty degeneration, nephritis, pneumonia, etc. The first effect on the blood is coagulability due to the liberation of a nuclealbumin by the action on the erythrocytes and vessel-wall lining, and may result in sudden death from thrombosis. Noncoagulability follows secondarily. In the treatment, he advises amputation, a tight ligature, or deep scarification to prevent absorption. Substances to neutralize the poison are not reliable, except, perhaps, hypochlorite of lime. Alcohol is of no use except as a stimulant. Lavage of the stomach will aid elimination. Danger symptoms are met as follows: Normal salt-solution injections to take the place of salts lost from the plasma may prevent coagulation. Artificial respiration long continued may tide over the danger period to the nervous system. Strychnia and atropin are valuable respiratory stimulants. Calmette's antivenene has a decided chemical action on the toxins and has proved itself of value in prolonging life until the danger is over. Mental encouragement should be persisted in. [J.s.]

2.—Quintard speaks of **erosion of the stomach** as a loss of the mucosa, but the process extends no deeper and there is no elevation or induration of the edges. He thinks the term is necessary for clinical purposes to describe a class of cases in which the pain after eating is moderate, there is decided loss of flesh and strength, fragments of mucosa are found in the washings, and there is hypochlorhydria or anachlorhydria, and possibly lactic acid is present. It is a complication of numerous pathologic conditions. The treatment is a spray of 1 : 500 solution of silver nitrate by an Einhorn atomizer every other day. After 3 applications there is usually marked local and general improvement. [J.s.]

3.—Moschcowitz believes that in **genital tuberculosis** in the male the primary focus is frequently a nodule in the epididymis. In the course of a few weeks, the tubercle-bacilli will be carried by the seminal secretion into the corresponding vas deferens and gradually travel upward until the entire vas deferens to the seminal vesicles is involved; very soon this also becomes tuberculous. The next step is the infection of the corresponding lobe of the prostate. For the radical cure of this condition castration alone will evidently be futile; every portion of diseased tissue must be removed including the entire vas deferens, together with the corresponding seminal vesicle. The following procedure is recommended: Castration is performed by the usual scroto-

inguinal incision, with the exception that the vas deferens is not divided at the level of the vessels, but is isolated from the other structures of the spermatic cord and left in connection with the testicle; then as much of the vas deferens is pulled out of the inguinal canal as can be done without danger of tearing it off. After placing a ligature around it, it is divided, and the proximal end is seared with a Paquelin cautery, so that in manipulation no opportunity shall be given to infect the channel of the vas deferens, between the peritoneum and the bladder. After removal of the testicle the external incision is closed. The patient is then placed in the lithotomy position, a sound is introduced into the bladder as a guide, and a curved incision is made in front of the anus, extending from one tuberosity of the ischium to the other—after division of the superficial and deep perineal fascia, and of the tendinous union between the bulbo-cavernosus and external sphincter, the urethra being held front by a blunt retractor, the space between the rectum and urethra is deepened by blunt dissection, until the anterior portion of the levator ani, the so-called levator prostatae, is reached. This is divided by scissors, the muscle retracts, and the prostate and diseased seminal vesicle are reached by the finger. The finger of the left hand is now introduced into the rectum, and hooked over the upper border of the prostate; traction is exerted, and much of the prostate and seminal vesicle can be brought into view. Should this be impossible on account of adhesions, the seminal vesicle may be grasped by a clamp and gentle traction and manipulation made to liberate it. Proceeding in this manner, the entire unruptured seminal vesicle and the remaining portion of the intraabdominal part of the vas deferens are brought into view. The seminal vesicle and vas deferens are then attached only by the ejaculatory duct, which can be readily cut off. Tamponade of the wound, and the insertion of one or two sutures partly closing the perineal incision, terminate the operation. Moschcowitz reports operating on a man of 35 by this method. Uneventful recovery followed the operation and the patient was cured of genital tuberculosis, but he died eventually of pulmonary tuberculosis. [M.B.T.]

4.—Davis says the **liver** is the connecting link between **digestion and elimination**. It completes digestion and finishes disintegration, rendering it possible for the substances to be excreted by the kidneys. The most frequent cause of nephritis and diabetes is inadequate constructive and destructive metabolism in the liver. Drugs correcting the liver functions often prove to be the best diuretics. [M.B.T.]

- 1. A Simple and Efficient Treatment of Talipes Calcanus Paralyticus in Young Children. V. P. GIBNEY.
- 2. In What Relation does Occupation Stand to Tuberculosis? W. FREUDENTHAL.
- 3. Multiple Traumatic Hemorrhages of the Liver Associated With Multiple Pulmonary Emboli of Liver-Cells and Giant Cells Resembling Bone-Marrow Cells. ALFRED SCOTT WARTHIN.
- 4. Post-Apoplectic Temperature and Disturbances of the Alimentary Tract; Their Management. HENRY LYLE WINTER.

1.—Gibney says that a simple and efficient method of **treating talipes calcaneus paralyticus** is to put the foot in extreme extension and to keep it there by some form of apparatus. In children he employs plaster-of-paris, and in a number of cases has obtained very satisfactory results, some of the patients obtaining practically normal limbs. In adults plaster-of-paris possesses many disadvantages, so that it is better to immobilize the foot with some form of leather splint properly supported by steel, but the same principle, **immobilization in extension**, holds good. [G.W.B.]

2.—Freudenthal says that statistics show that **tuberculosis** causes a **higher death-rate** among the population that receives the **smallest incomes**. Among 1,152 tuberculous male patients at the Montefiore Home in New York, 389 were tailors or engaged in allied occupations. The reasons he gives for this fact are that most of these men are Poles or Russian Jews, and they not only work in sweat shops, but their homes are in the crowded tenement houses where they have the same bad hygienic surroundings. These

people suffer from chronic atrophic nasopharyngeal catarrh, and the dried secretions offer a good medium for the growth of the bacillus and an open door to invasion. [J.S.]

3.—Warthin reports a most interesting case of **traumatism of the liver**, caused by the handle of a hay-fork passing through the perineum into the abdomen. The sufferer died, on the third day after the injury, from septic peritonitis developing as the result of numerous intestinal perforations. At the postmortem, numerous areas of contusion and hemorrhage were found throughout the liver, in which both the portal and hepatic vessels were found ruptured. In the lung there were many fresh hemorrhagic infarcta caused by the lodgment of giant cells in the capillaries. These giant cells resembled apparently exactly those seen in the lung capillaries in cases of eclampsia, and supposed to be placental cells. After a careful study of this case and the literature on the subject Warthin offers the following conclusions: 1. Mononuclear and multinuclear giant cells appear in the pulmonary vessels in a large variety of widely varying pathologic conditions. In some cases they also appear in the capillaries of the liver, spleen, and kidneys. 2. The source of these cells may be either the placenta, bone-marrow, spleen, or lymphatic glands, but we have no means of absolutely determining such origin except in the cases where portions of the villi or of marrow tissue are also found. 3. It is not possible with the present staining methods to differentiate between simple giant cells arising from the syncytium, periplacental tissue, bone-marrow, spleen or lymphatic glands. 4. It is probable that in the majority of cases the giant cells found in the lung-capillaries arise from the bone-marrow, and that in some cases (pregnancy) the metastasis is physiologic, while in others it may be the nature of an agonal or pre-agonal leukocytosis. In other conditions it may be the result of diseased conditions in the bone-marrow itself. The exact significance of the process remains yet to be discovered, but it is probably of far greater importance than that of an accidental occurrence, as it has generally been considered. In the case above mentioned liver-cells were found in the lung-capillaries along with the giant cells. [O.B.W.]

4.—Winter thinks the **post-apoplectic temperature** found at the time of returning consciousness in the majority of cases not due to local infection, is caused by the absorption of infective material from a torpid alimentary tract. In place of the usual routine of calomel, he advises dram doses of hydrogen peroxid, repeated as necessary. This drug checks fermentation, and is slightly stimulating to digestive functions. In a number of cases in which it was tried, he found the axillary temperature reduced a few hours after its administration, and more rapidly on the paralyzed side. This was not due to vasomotor phenomena, but to a more rapid elimination of heat on the affected side as the alimentary condition was improved. The drug does not influence the pulse. It is administered with an equal quantity of glycerin. [J.S.]

Boston Medical and Surgical Journal.

September 13, 1900. [Vol. cxliii, No. 11.]

1. The Radical Cure of Hernia. J. COLLINS WARREN.
2. Actinomycosis. CHARLES ALLEN PORTER.
3. Four Cases of Actinomycosis. JOHN C. MUNRO.
4. Tendon Suture. EDWARD S. HATCH.
5. Method of Teaching Practical Medicine. THOMAS F. HARRINGTON.

1.—Warren gives the results of his experience in the **radical cure of hernia** in a series of 98 cases operated on in the Massachusetts General Hospital and in private practice between the years 1888 and 1900. It includes 74 cases of inguinal hernia, 7 of femoral hernia, 12 of umbilical hernia and 5 of ventral hernia. Great pains were taken to obtain the subsequent history of all cases operated upon over 1 year previously and answers were received from 62. In 4 of these death occurred from other causes, results unknown. This leaves 58 cases from which to obtain information as to recurrence. Separation of the cases into 2 groups—those operated upon between 1888-1894 and those between 1895-1900—shows the marked improvement aseptic technic has brought about. Prior to 1895 there were 33 cases operated upon, of which 16, or 48%, were infected; after 1895, of 65 cases, 9, or

16%, only were infected. All cases that did not heal by first intention throughout the wound, even the smallest stitch abscess, are classed as infectious. A careful analysis of the cases was also made to determine the best form of suture material. Silk, catgut, kangaroo-tendon, etc., were used. The results are decidedly in favor of silk as a suture material, though, since more thorough preparation of catgut in later years, the results following its use are much improved. As to the question of recurrence: Out of 58 cases in which an answer was obtained 1 year or over after operation, 45 were cases of inguinal hernia; and in 7 of these relapse was reported—that is, there were 84% of cures. In 3 cases of femoral hernia there was no recurrence; 2 cases of ventral hernia, no recurrence; and 8 cases of umbilical hernia, 3 recurrences. Comparing the inguinal hernias operated upon prior to 1895 and since, in the former there was 69% of cures, in the latter 92% of cures, showing that improved technic had an important influence upon the result. Warren does not agree with Coley and Bull that the age-limit should be placed at 50 years. It is in hospital practice that we see a larger number of hernias, usually of large size, in individuals above this age. They are, as a rule, patients who are unable to afford a truss, or do not understand how to apply it intelligently. It is precisely in this class that an operation seems to hold out hope of great relief. Among Warren's cases, 17 were operated upon who had passed that limit, with no recurrences. Great care in the preparation of the skin and careful isolation of the sac, closure by suture and excision, are considered specially important. [M.B.T.]

2.—Porter believes that **actinomycosis** is a much more common affection than is generally believed. In its clinical aspects there is little that is characteristic, and examination by microscope and culture is essential for a positive diagnosis. During 18 months' work in the Out Patient Department at the Massachusetts General Hospital, Porter has found 8 cases of actinomycosis in about 60 so-called alveolar abscesses examined, and 4 cases were found by other surgeons. Six cases occurred within 3 months, and 4 within a week; so we may conclude that the disease cannot be one of great rarity. Reports of Porter's 8 cases are given. The infection enters most frequently near a carious tooth, or is carried in by a foreign body through the mucous membrane of the mouth or pharynx. The process is essentially sub-acute or chronic, the infection is usually mixed with ordinary pyogenic organisms, it is rarely painful, and under the microscope the disease is characterized by the formation of an unusual amount of dense connective tissue. The mere presence of "sulphur granules" is not by any means conclusive. Small, round masses of fibrin or tuberculous debris, or round masses of mouth bacteria, or *Leptothrix buccalis*, occasionally appear very like a true colony. With reference to treatment, two facts speak strongly for the self-limitation of the disease in the majority of cases. Though it cannot be rare, few cases enter the hospital with advanced actinomycosis of the jaw, and it seems, therefore, certain that many recover after simple incision of the abscess, or even natural rupture. It is surprising to find, on microscopic examination of sections, how infrequently the colonies are found in the walls of the abscesses, though the pus contained many granules. The surrounding connective tissue probably proves an effective barrier to the spread of the disease. Simple opening, curetting, and drainage have proved sufficient in many cases; though recurrences may be frequent, healing eventually takes place. When possible, excision of the inner half of the abscess wall or sinus is the best treatment. External drainage is advised, and potassium iodid internally is thought to be of benefit in some cases. [M.B.T.]

3.—Munro reports 4 cases of **actinomycosis**: A man of 45 was operated upon for encysted empyema in the region of the left ninth rib posteriorly. A portion of the rib was removed and the cavity was curetted and packed. The patient's general condition did not improve and death resulted a few weeks later. In the 3 remaining cases the jaw was affected, the disease following a blow on the cheek in 1 case, fracture of the jaw in another, and extraction of a tooth in the third case. In all these cases apparent cure resulted from thorough curetment and antiseptic treatment of the abscess cavity. [M.B.T.]

4.—Hatch reports **tendon suture** following an incised wound of the wrist dividing the following structures: Tendons of the palmaris longus, flexor carpi ulnaris, and flexor sub-

2.—Crafts reports a case of family periodic paralysis. The name is of no scientific value, and applies only from the fact that the majority of cases have been reported in groups in families. European writers have reported cases of this disease, but only 3 cases in this country strictly conform to the conditions. The patient has been under observation for about 7 years. A man of 35 years, short, heavy build of body, hands and feet very large. His gait is waddling in character. Mentally he is keen and energetic. The legs, hips, and thighs are abnormally large and the arms, too, are heavy; but his muscular strength does not correspond at all to the development. His family history is distinctly neuropathic. He was 12 years old when the present condition made its advent. For 2 days he was unable to move any of his ex-

trémities, but on the third day he was up and about. Six months later the second attack occurred, and they have returned at irregular intervals since. The most serious attack occurred 3 years ago, following extreme exertion for a day. There was almost constant vomiting, with large quantities of bile, marked exhaustion, bad color, pulse weak, small, and rapid. Constipation or diarrhea frequently precedes the attack. The onset is always gradual, usually beginning in the hands and feet, and the duration of an attack varies from a few hours to about 3 days. In the extreme condition all muscles of the extremities, body, and neck are entirely relaxed. The chest-wall hardly moves at all on respiration, which seems entirely confined to movements of the diaphragm. There are no manifest vasomotor disturbances, no pains, and no sensory changes. The normal reactions of both muscle and nerve to either galvanism or faradism diminishes in proportion to the motor loss in the muscle under test, and tetanizing currents will elicit absolutely no response when the paralysis is complete. The tendon reflexes are abolished, the plantar is gone, but the cremasteric is at times present in slight degree. During the attack the pulse is always accelerated. Examinations of the blood, urine, and feces have been carefully made. From the feces a poison was eliminated which produced in rabbits and guinea-pigs a paralysis which gradually disappeared in 48 hours. Goldflam, Taylor, and Mitchell became convinced of the presence of some form of autointoxication (an opinion shared by the author), but were not able to isolate the poison. It would appear, further, that this poison is developed only at intervals, considering the widely varying intervals between the attacks. The way is therefore pointed out for the development of a rational method of treatment of an antitoxic nature, but this probably cannot be accomplished until the poison has been fully identified and the seat of its evolution determined. [C.A.O.]

3.—Brown gives a clinical report of 3 cases of **permanent nonprogressive ataxia**. The first case was a man of 30, family history fairly good. At 18 he was subject to very hard labor, and drank some, but not to excess. He denies venereal disease of any kind. At this age he began to suffer from severe frontal headache, became gradually blind, lost the use of his arms and legs, and in 2 or 3 months was entirely helpless. For several months he continued in this condition, and then improved very slowly for a year, since which time he has been practically in his present condition, which is that of intense muscular incoordination and great exaggeration of the superficial and deep reflexes. The voice sounds and grimaces when speaking are much like those observed in some cases of idiocy, so that one might be easily led to form an erroneous impression as to the patient's mental state. The second case was a woman of 28, vigorous and healthy as a child and young woman. She was married at 19, and a year later a child was born; nothing abnormal. When 23 she again became pregnant, and from the first suffered intensely with nausea and vomiting. All known remedies were tried in vain and an abortion was carefully performed. Symptoms of severe sepsis followed this. After recovery the ataxia was so great that she could not stand alone, feed or dress herself, although the gross strength was little, if at all, reduced. The reflexes were exaggerated, there was great difficulty in speaking, although no mental impairment. There was no change in her condition until she died at the age of 28 with symptoms of cerebral meningitis. The third patient was a woman of 28, general health good up to present illness. About the eighth month of pregnancy she suffered from grip, followed by severe headache. Finally somnolence, loss of reflexes, ptosis, with no attention to the bowels or bladder. A healthy child was born 11 days after the headache began without the mother showing the slightest appreciation. After several days mental activity gradually returned. The strength partly returned, but there was extreme ataxia which has continued until the present time—a period of over 6 months. These cases, from a clinical side, have much in common; a more or less severe, acute, and probably infectious illness, resulting in profound general muscular ataxia, particularly in the muscles of articulate speech. No lasting impairment of special sense or general sensation, general health good after primary illness and mental condition normal. The essential question is, what part of the normal adult brain has to be injured in order that general ataxia shall result. Assuming that the cerebellum

exercises a predominating influence upon the coordination of voluntary muscular movements, then it would not be unreasonable to assume in the cases cited that one effect of the primary disease had been to injure permanently those parts of the organ subserving this function, or a considerable number of the neuron processes connecting it with other parts of the nervous system. If it is conceded that the influence of the cerebellum is paramount in controlling muscular coordination when the position and extent of the various tracts are remembered which connect it with other parts of the nervous system, it is not difficult to understand how far apart pathologic processes may be situated, and yet, by destruction of one of these connecting paths, throw the cerebellum out of circuit, so to speak, and give rise to ataxia. In many cases of the progressive types of ataxia the pathologic process apparently begins and is for a long time confined to the spinal cord, while in the cases described it was apparently in the brain. [C.A.O.]

4.—Nonne publishes a reply to a paper on **paralysis agitans** by Dana in the November issue, 1899, of the *American Journal* in which he states that Dana takes occasion to differ radically from an opinion which he had expressed on the **spinal-cord changes in paralysis agitans**. He says the changes found by Nissl's method are identical with those found by Dana, that there was no difference between the changes found in senile cords and those in cases of paralysis agitans, and that the changes described by Dana are those usually found in a condition of cachexia. German authors do not consider such changes pathognomonic. He says this alteration of the ganglion-cells had been observed by him in his own cases of anemia and in those that came under Goebel's notice. The fact that these changes in the ganglion cells in cases of paralysis agitans often occur, and are not looked upon as pathognomonic of paralysis agitans has already been stated by Sander. [C.A.O.]

5.—Dana in reply to Nonne's article says that he and Nonne do not differ much and that his views have been misinterpreted. These were as follows: 1. That paralysis agitans was a very strikingly distinct clinical entity and quite different from premature senility; hence it was probable we should some time find its anatomic basis. 2. In his experience he did not find the pathologic picture of the cords in paralysis agitans and senility identical. 3. That there is a rather unusual degree of degeneration and vascular and sclerotic change in the anterior horns in paralysis agitans, and more here than in any other part of the central nervous system so far as yet known. 4. He says his view that in the disease there is an interruption in the flow of nerve impulses from the corticospinal dendrites to the anterior horn cells is only a working hypothesis, but that it is in harmony with pathologic findings, as Nonne admits. [C.A.O.]

6.—Crowder briefly reviews the literature bearing on **tuberculosis of the cecum**, and reports 2 cases. The first was a colored girl of 14, whose immediate family history was fairly good. Her trouble began about 8 months before she applied for treatment. There were cramp like pains in the abdomen, which at first were irregular and diffuse, but later became more frequent and were attended by much vomiting. Only liquid food could be retained and she had lost much flesh. On physical examination a mass the size of a large lemon was found lying deep in the abdomen, half way between the umbilicus and the anterior superior spine. The mass was tender, smooth, very slightly movable and apparently free from the anterior abdominal wall. On operation the tumor was found to involve the entire circumference of the bowel at the ileocecal junction. The lymphatic glands lying in the mesentery next to the cecum were firm, white and swollen. No vermiform appendix was found. The mass, including about 2 inches of the bowel on each side, was excised and an end-to-end anastomosis between the colon and the ileum was performed. The patient made a good recovery. A microscopic examination of the mass showed it to be tuberculous. Since the patient has developed no evidences of other tuberculous manifestations, it appears that this was a primary, localized tuberculosis of the bowel. The second case was a woman of 54. About 3 years before entrance to the hospital tumors were removed from the left breast and left axilla, but there is no definite knowledge of their nature. The patient gave a history of a blow in the right inguinal region. Succeeding this there was pain on walking, which radiated down the leg. Later there appeared a swelling in

the right groin, which was incised, revealing an abscess. There remained to the time of her death a fistula in the right groin, which permitted the escape of fecal matter. A postmortem examination showed tuberculosis of the lungs and peribronchial glands; amyloid spleen, chronic interstitial nephritis; and **carcinoma of the cecum associated with tuberculosis**. It appeared that the malignant growth had taken its origin from the margin of an old tuberculous ulcer. This hyperplastic form of tuberculosis as found in the intestine is usually located in the cecum, and most often takes its origin at the ileocecal junction. [C.A.O.]

7.—Herzog and Lewis discuss that type of mixed tumors of the kidney which has been attracting attention for a number of years, the true character of which has been fully recognized only quite recently. These tumors attract attention not from urinary symptoms, but by increasing the size of the abdomen. They grow rapidly, speedily lead to malignant cachexia and destroy life with or without the formation of metastases. They are the **embryonal renal adenosarcomas of childhood**. With reference to their origin, which has excited much investigation and controversy, Birch-Hirschfeld believes that they arise from the remnants of the Wolffian body. Wilms believes, however, that they arise from inclusion of the very earliest embryonic development, namely, from the undifferentiated mesoblastic tissue, which later on in normal embryonic development gives rise to the Wolffian body and to the myotome. The myotome, he claims, is responsible for the presence of the striated-muscle fibers in the tumors. The authors refuse to accept the explanation of Wilms, but lean strongly to that of Birch-Hirschfeld. They believe that these tumors owe their origin to inclusion which is formed in the following manner: The nephrotome is not cut off at the normal site, but in such a manner that a part of the myotome is severed from the main mass and remains in connection with the nephrotome. The separation may take place so that only a part of the myotome proper is cut off, or a part of the sclerotome may likewise be taken along. If the former is the case we have the matrix for striated muscle-fibers only; if the latter occurs, we have also the matrix for cartilage. If now we assume that a part of the nephrotome (Wolffian body) to which tissues of the myotome proper, or the latter and sclerotome have become adherent by an abnormal process of embryonic separation, becomes included in the permanent kidney, we have a matrix containing all those embryonic elements which occur in the mixed renal tumors, namely, striated muscle-fibers, cartilage, other connective-tissue elements, and epithelial glandular structures. The latter are derived from the excretory tubules of the nephrotome. [C.A.O.]

Münchener medicinische Wochenschrift.

July 10, 1900. [47. Jahrg., No. 28.]

1. A Contribution to our Knowledge of the Effects of Turpentine. H. SCHULZ.
2. A Contribution to Immunity Instruction. FREIHERRN V. DUNGERN.
3. Etiology of Fibrinous Bronchitis. OTT.
4. A Case of Weil's Disease. ALFRED SCHITTENHELM.
5. A Case of Hysterical Muteness, Doubtless Caused by Intoxication. ERNST BLOCH.
6. Experimental Attempts at Hand Disinfection. PAUL and SARWEY.
7. Migration of Foreign Bodies in the Small Intestines After Laparotomy. WUNDERLICH.

1.—Schulz's studies on the influence of **minute doses of turpentine** have led to results that are exceedingly strange and almost incredible. Several medical students took turpentine in 1% solution. The first took during 5 days a total of one drop; the second took in 10 days 2 drops; the third during 8 days, a little less than 2 drops; and the fourth during 9 days, about 2 drops. The first man had some gastric pains, headache, nausea, belching, and a marked sense of fatigue. More or less similar symptoms were present in the other cases. In a second series of experiments the dose was still smaller. The first subject took during 8 days altogether one-fifth of a drop of turpentine. In a third series the subject took during the course of 23 days altogether

one-half drop. There was a reduction in the pulse-rate. Constipation was the rule in nearly all of the subjects, which shows that turpentine in small doses may, even in the absence of lead, produce constipation. There was no harmful effect on the urine. In 2 cases acne was produced. While it would not be scientific to deny that turpentine in such infinitesimal doses could produce all the symptoms which Schultz found, it seems to us that the psychic element must have influenced both the experimenter and his subjects. [D.R.]

2.—Von Dungern brings forward further proof of the **lateral chain theory of immunity**, as enunciated by Ehrlich, which had been attacked by Metchnikoff. He also succeeded in producing immune serum by means of the injection into guineapigs and rabbits of cows' milk. Such an immune serum is capable of killing ciliated epithelial cells introduced into the abdominal cavity of guineapigs. The serum has also to a certain extent the property of dissolving the blood corpuscles of cattle. This shows that the immune serum possesses at least two *immunkörper*, one acting on the ciliated epithelial cells of the trachea of cattle and the other on the red blood-corpuscles. Its action on the former is much more powerful than on the latter. This proves that in milk are contained the same specific substances as in the epithelial cells which produce the milk, by means of which it is possible to excite the formation of a powerful serum that is destructive of epithelial cells. The author has been engaged in an attempt to produce an epithelial immune serum with human milk, thinking that it would perhaps be destructive to the epithelial cells of cancer. So far the injection of human milk into dogs and rabbits has not produced an immune serum having such properties. [D.R.]

3.—A case of **fibrinous bronchitis** in a boy of 15. The fibrinous coagula on culture and microscopic examination showed the presence of the pneumococcus and Staphylococcus pyogenes aureus. It is probable, the author thinks, that the patient had a primary simple catarrhal bronchitis, which was kept up by his occupation. He was a polisher of shears, knives, and other metal tools. The irritation produced by the fine metallic particles prepared the way for the localization of the bacteria. The chronic course of the case was probably due to the addition of mixed infection to the infection of the pneumococcus. [D.R.]

4.—A coppersmith of 31 was suddenly taken ill with headache, delirium, fever, gastric and general symptoms, and a mild angina. Jaundice, swelling of the liver and spleen, a mild nephritis, muscular pains, and skin-lesions soon developed. The disease ended by lysis. Convalescence was slow, and during it the pulse was rapid. Bacteriologic examination of the blood was negative. There was nothing in the history throwing any light on the origin of the Weil's disease. [D.R.]

5.—A case of **hysteric mutism** preceded by hysterio-epilepsy and apparently excited by intoxication with carbon monoxid. It seems probable that as the patient had shown some signs of nervous disturbance previously, the CO poison was merely the exciting cause of a dormant neurosis. [D.R.]

7.—Wunderlich reports 2 cases in which **tamppons** were evidently **left behind** after abdominal operations. In the first case the gauze tampon was passed from the bowel through the anus and the patient made a good recovery. In the other the patient died within 36 hours subsequent to the operation and the tampon was found free in the abdominal cavity and unaccompanied by any inflammatory reaction. [G.B.W.]

9. Concerning Diabetes Insipidus. STRUBELL.

1.—Erb calls attention to the existence of larval forms of tabes, the early recognition of which is difficult. A number of illustrative cases are cited. The disease generally manifests itself by lancinating pains, slight paresthesia, and diminished sexual power. In one case there was a unilateral Argyll Robertson pupil. In another there were merely bladder and sexual weakness, slight fatigue, and paresthesia, and some swaying with the eyes closed. The reflexes in 5 cases were present and active, even after the symptoms had persisted from 4 to 7 years. In all of the 5 cases cited an undoubted secondary syphilis had preceded. Another group of cases in which the diagnosis is difficult is composed of those with visceral crises. In all of these a careful examination may reveal perhaps a sluggish or absent reaction in both pupils or in one pupil only, absence of the Achilles reflex, slight indication of Romberg's symptom or of disturbance in sensation. Erb considers that the presence of lancinating pains, bladder and sexual weakness, lassitude, trifling paresthesia, Argyll Robertson pupil, and slightly developed Romberg's symptom, are sufficient to justify the diagnosis of tabes, even if the reflexes are present and the other characteristic symptoms are absent. The demonstration of a previous syphilitic infection practically clinches the diagnosis. Such cases may remain always rudimentary, or they may develop into the typical grave locomotor ataxia. Erb uses mercurial inunctions freely in these forms. [D.R.]

3.—Hirsch reports a most interesting case of **hernia of the diaphragm** in a man of 34. The objective symptoms resembled very closely a left-sided pneumothorax. The patient, however, was in good health and did not give a history of lung-disease. Ever since early childhood the patient had suffered more or less from gastric distress, especially following eating, and had been treated at different hospitals without obtaining relief. Physical examination gave unmistakable signs of a cavity in the lower part of the left side of the chest, and it was ascertained that since childhood the heart had been situated on the right side. Also it was noticed that physical signs varied greatly. After eating, the supposed cavity increased in size, and finally the true state of affairs was suspected. The diagnosis was confirmed by inflating the stomach and by radiographs made after the patient had swallowed a quantity of bismuth, and, secondly, after a stomach-tube filled with mercury had been introduced into the stomach. These tests show that the whole of the stomach was displaced and occupied a position above the diaphragm, in the left pleural cavity. [O.B.W.]

5.—Braatz advances a rather new theory as to the way in which alcohol does good as a **disinfectant** for the hands. He says that the skin naturally contains a certain amount of air chiefly in the ducts of the glands, and that it is the presence of this air which prevents, to a very large degree, the watery disinfectants from gaining access to the bacteria residing in these recesses. Alcohol, he claims, will replace this air and thus readily penetrate into the ducts and act directly on the germs contained therein. [G.B.W.]

6.—Sicherer says that the oxycyanid of mercury is not as powerful an antiseptic as the bichlorid, though Pastilli's oxycyanid is stronger than that of Grouvelle. [G.B.W.]

9.—Strubell defends himself against the attacks made upon him by lay and medical writers, on account of his practical **incarceration of a man with diabetes insipidus** in whom he wanted to study metabolism. While he seems to show that he did not transgress the limits of the allowable, we yet feel that he laid himself open to criticism. His own devotion to his work, which made him visit the patient from 8 to 10 times during the day and from 5 to 6 times during the night, is very commendable; but it would not be considered by the majority of persons whose opinion, even if not well founded, must be respected, as excusing the procedures dictated by the author's scientific zeal. Much has been made by the lay press of the man's escape through the roof of his room, but Strubell clearly shows that the man himself was willing to submit to the investigation and returned after his escape for a continuation of the experiment. [D.R.]

Wiener klinische Wochenschrift.

July 12, 1900. [13. Jahrg., No. 28.]

1. The Etiology of Basedow's Disease and Thyroidism. ROBERT BREUER.
2. Our Knowledge of Recurrent Tetania Gravidarum. C. HÖDLMOSE.
3. A Mud Obtained from Salzberg by Ischler. E. WIENER.
4. Comment upon the Essay, in No. 25 of this *Wochenschrift*, of G. Holzknecht, "The Radiographic Appearance of Pathologic Processes of the Thoracic Aorta." M. WEINBERGER.

1.—A man of 43, of healthy antecedents, following an acute suppurative thyroiditis due to staphylococci, developed **exophthalmic goiter**, of a grave type, with well-marked ocular symptoms. The disease ended fatally in about six months under the picture of an acute psychosis. The autopsy showed the remains of the abscess and a diffuse hyperplasia of the thyroid gland. The parenchymatous viscera were the seat of degenerative changes such as are found in intoxications or acute infectious diseases. The author believes that his case clearly proves the thyroid origin of the exophthalmus of Graves' disease. It had been held by some that the existence of exophthalmus could not be explained on a thyrogenic origin and that this constituted a strong argument against Möbius' theory of the thyroid origin of the disease. [D.R.]

2.—Hödlmoser reports a case of **recurrent tetany** in a woman of 33. The attacks set in at about the middle of each of 7 pregnancies and continued until the end. From the history it was apparent that the patient had had the attacks of tetany before her marriage. The pregnancies seemed afterwards to be the exciting cause. Tetany is much more frequent during lactation than during the period of pregnancy. [D.R.]

Sundry French Journals.

1. Kernig's Sign in Meningitis. P. ROGLET. (*Gaz. Heb. de Méd. et de Chir.*, July 15, 1900. 47me Année, No. 56. Paris Thesis, 1899-1900. No. 344)

1.—Kernig's sign is characterized by the absolute impossibility of obtaining complete extension of the leg on the thigh, when the patient is sitting and the thigh is flexed at a right angle to the trunk. The cause of this functional trouble lies in the contracture of the flexor muscles of the leg. The contracture disappears, however, and complete extension of the knee joint is easy when the patient assumes the dorsal decubitus. While it is usually bilateral the phenomenon is sometimes found on one side only. The intensity of the contracture may vary from day to day and in order to be sure that the sign is not present it is necessary to look for it several times. Often the phenomenon does not appear until the third or fourth day of an attack of **meningitis** and, indeed, in some cases of tuberculous meningitis it has not been discovered until the seventeenth day. The time of its disappearance is also variable. It may persist until death supervenes; it may disappear during the preagonal period; and it has been known to remain during convalescence. The value of the sign is real but not absolute. When it exists, it is useful in differentiating cerebrospinal meningitis from certain forms of influenza, typhoid fever, infantile paralysis, tetanus, and meningismus. Its absence in any case would not justify one in excluding the diagnosis of meningitis or of irritation of the meninges. Kernig's sign is produced by irritation of the meninges of the lower portion of the spinal cord and of the nerve roots that constitute the *corda equina*, although it is no indication of a distinct lesion of these structures. The experiments of Roglet on rabbits indicate that increase of pressure of the cerebrospinal fluid is not the cause of the phenomenon. In the healthy subject, placed in the sitting posture, with the thighs flexed at right angles to the trunk and the legs completely extended, the fibers of the flexor muscles of the knee-joint are extended to their extreme limit and their elasticity is almost completely exhausted. If now, under an irritation of the spinal cord or of the roots of the spinal nerves, the muscular tonicity is increased and the elasticity and the length of the fibers are diminished, they become too short to allow of complete extension of the leg upon the flexed thighs and Kernig's sign appears. [J.S.M.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Tropon as a Food in Pulmonary Tuberculosis.—

Knopf (*Prophylaxis and Treatment of Pulmonary Tuberculosis*) writes as follows: "Of the many food-substances which have been recommended recently as especially valuable in the dietetic treatment of tuberculosis, I have used most extensively and with most satisfactory results the new product, tropon. Tropon is a tasteless and odorless, albuminous preparation in the form of a yellowish-brown powder, obtained through a complicated chemical process from animal and vegetable substances. That such a substance should be of value in the treatment of consumption seemed evident. I selected patients with whom I had had unusual difficulty in increasing their weight, with some among them on account of their aversion to fats. To summarize the results obtained, I may say that with from one to two ounces per day the average gain in 20 days was about one pound and a half, including one case with negative results. I must, however, add that these patients were mostly ambulant. In Weicker's sanatorium in Goerbersdorf, where patients in all stages of the disease are admitted, from out of 18 cases 15 responded to the treatment, gaining in the average 2½ pounds in 4 weeks. The relatively better results obtained in the sanatorium must be ascribed to a better supervision and a more regular administration of the tropon than is possible with ambulant patients. Tropon has since been extensively used with satisfactory results in the clinics of von Leyden and Senator in Berlin; Schmelsky and Klein in Hamburg. It can be administered with mush, thick soup, cocoa, chocolate, milk, mashed potatoes, rice, sago, tapioca, etc. It must be borne in mind that tropon is not soluble in water, and consequently falls to the bottom in clear liquids, coffee, and thin soups, and when taken with such it must be constantly stirred. It can be advantageously taken with the yolk of an egg and some sugar. For those of my ambulant patients who have not the conveniences of home life, I prescribe the tropon to be taken by the aid of a wafer (a teaspoonful at a time). Considering that tropon is really an able substitute for the albumen in other foods; that it rarely causes digestive disturbances; that it can be taken for a long period of time without aversion, and that it is excessively cheap, we may look upon the new product as a most valuable adjuvant in the dietetic treatment of phthisical patients."

Diarrhea of Phthisis.—Burney Yeo states that in advanced cases he has found the extract of coto bark very efficacious. He prescribes it in the following form:

- R.—Fluid extract of coto 60 minims.
 - Compound tincture of cardamom..... 60 minims.
 - Mix and triturate slowly with:
 - Mucilage of acacia..... 3 drams.
 - Simple sirup..... 2 drams.
 - And add sufficient water to make..... 6 ounces.
- Dose: One tablespoonful.

Ichthalbin in Intestinal Diseases.—Rolly (*Merck's Archives*, August, 1900) draws the following conclusions from the use of ichthalbin in 28 cases of subacute and chronic enteritis: Ichthalbin was given in doses up to 2 drams daily for a long time without harmful results, and was always eagerly taken. It caused no constipation, even in the larger doses, nor any symptoms of irritation of the intestines or kidneys. In our metabolism tests it facilitated the albumin intake, while at the same time it diminished the nitrogen elimination via the urine, and heightened the utilization of the ingested nutriment. Doses of 5 to 8 grains of ichthalbin sufficed to raise the appetite and increase the body-weight; hence the remedy appears to be serviceable as a tonic. In our four series of tests daily doses of 23 to 45 grains greatly reduced the quantity of ethyl-sulfates, and lessened intestinal fermentation, even though the dejections only gradually lost their fetid character. Under otherwise constant conditions (diet, etc.) daily doses of 23 to 45 grains of ichthalbin had a satisfactory, at times very excellent, in-

fluence on simple chronic enteritis, as well as in cases complicated with peritonitis or tuberculosis. Subacute gastric intestinal catarrhs were to some extent satisfactorily influenced, but in acute cases an uninfluenced action could not be observed.

The Abortive Treatment of Bubo.—Christian (*Therapeutic Gazette*, August 15, 1900) states that he has obtained most satisfactory results from the use of an ointment of drugs alterative in character combined with speedy pressure obtained from the use of a spica bandage. The ointment to be used for this purpose is made up as follows:

- R.—Ointment of mercury.....
 - Ointment of belladonna.....
 - Ichthyol.....
 - Lanolin.....
- } of each 2 drams.

If the bubo be seen early, no heat or redness being present, a piece of surgical lint spread with the ointment is applied directly to the swollen gland; over this is placed a piece of oiled silk of the same size. A large pad of cotton is next applied, and firm continuous pressure is obtained by the application of a wide spica-of-the-groin bandage, two bandages being employed. This treatment is applied every other day until, in cases in which it acts successfully, entire resolution of the bubo is accomplished—usually a period of 10 days to 2 weeks. Twenty buboes have been treated in this manner during the past year in the Philadelphia Polyclinic. Of these 12 were aborted, 8 of the cases following gonorrhea, and 4 accompanying chancreoid. Of the 8 cases in which abortive treatment failed, 6 were cases of tubercular adenitis. In these instances, however, it was early apparent that resolution would not occur. From a careful study of these cases the author has become firmly impressed with the belief that fully 50% of buboes, other than tubercular, can be successfully aborted by the plan of treatment outlined.

Eruetation, Regurgitation and Ruminantion.—Lincoln (*New York Medical Journal*, March 24, 1900) states that ruminantion is usually caused by heredity, custom or imitation. The best treatment is removal of the cause, having meals served in company, and the administration of some very bitter preparation. The following is suggested:

- R.—Fluid extract of condurango.)
 - Fluid extract of quassia.....
 - Compound tinct. of gentian.)
 - Tincture of nux vomica.....
 - Tincture of capsicum.....
- } of each 20 minims.
- } of each 10 minims.

Neurasthenia.—Dornblüth (*Therapeutische Monatshefte*, July, 1900) lays great stress upon the hygienic and regimantal treatment. Drugs, however, are often of great service. He believes that codein is particularly useful, and that it exerts, apart from its narcotic properties, some special influence on the nervous system. The organic salts of iron, bromids, and arsenic are often used with advantage. Insomnia may be a troublesome symptom; when such is the case the patient after partaking of light supper should give himself up for the rest of the evening to absolute relaxation of mind and body. A little food before retiring is sometimes beneficial. For inducing sleep the author recommends a hot foot-bath, a general bath (70°—76° F) with gentle friction, or Preisnitz pack. Valerian, kryofin, lactophenin often prove efficient, but in obstinate cases their use may be preceded for a few nights by trional, sulfonal, or dormiol.

Levulose in Diabetes.—The *Therapist* for July 16, 1900, quotes an article on this subject by Andrea Ferrannini, which appeared in *Il Policlinico* for November, 1899. The author draws the following conclusions from his experiments:

When glucose continues present in the urine of a diabetic subject, in spite of the diet being exclusively albumino-adipose, the administration of levulose augments the quantity of sugar contained in the urine.

When the sugar disappears from the urine, the diet being much scantier, although exclusively albumino-adipose, we may administer 13 drams of levulose in 24 hours without causing it to reappear in this urine; but the quantity of levulose may not be repeated on the following day, as sugar would then show itself. It is only with a dose of 6½ drams of evulose administered on alternate days that the sugar does

not show itself in the urine, even when this alternate treatment is continued for a protracted period of several days.

This small dose of 6½ drams of levulose administered on alternate days, when not eliminated as sugar in the urine, saves the consumption of the nitrogenous substances in a much greater proportion than agrees with the law of the thermo-dynamic equality of the articles of food, so that this effect is also due to other bio-chemical properties, which have not yet been ascertained.

Dysentery.—According to the *Medical Fortnightly* the following combination is useful:

R.—Magnesium sulfate.....	1 ounce.
Tincture of aconite.....	4 minims.
Morphin hydrochlorate.....	½ grain.
Spirit of camphor.....	10 minims.
Water.....	3 ounces.

A teaspoonful every 2 hours until character of stool changes, then at longer intervals.

Rheumatoid Arthritis.—Nestor Tirard (*Medical Treatment of Diseases and Symptoms*, 1900) writes that it is essential to make careful inquiry as to the possible connection of the disease with any menstrual irregularity, which may perhaps be corrected, and also to treat the general health by the free use of alterative tonics. Iron arsenate (⅞ to ⅓ grain) or sodium arsenate (⅞ to ⅓ grain) may be conveniently administered as a pill in conjunction with ferrous sulphate, if there is marked tendency to anemia. If the patient experiences any difficulty in taking this pill, sodium arsenate may be given in solution with iron citrate, or with the sirup of ferrous iodid, or, if the digestion appears to suffer from the use of arsenic, the sirup of ferrous iodid, ½ to 1 dram, may be given in water three times a day. Although this drug is frequently of very great service, complaint is sometimes made of its persistent taste, which is due doubtless to the absorption of iodine and its gradual elimination by the salivary glands. When there is evening rise of temperature, together with slight night-sweats, quinin is often of service. A grain or a grain and a half may be added to the iron arsenate, or it may be given in solution with dilute sulfuric acid, or in pill with extract of nux vomica and extract of belladonna. Ordinarily under this treatment the appetite improves and the temperature falls. When there is marked indication of debility, codliver oil may be of service. Many observers contend that they obtain better results from the steady employment of this drug than from any other form of medication. Constipation must be counteracted. Sulphur in comparatively large doses is the best laxative. The confection of sulphur may be administered night after night, but in general it is found that preference is expressed for the repeated use of the sulphur lozenge:

R.—Precipitated sulphur.....	5 grains.
Potassium bitartrate.....	1 grain.
Sugar.....	8 grains.
Powdered acacia.....	1 grain.
Tincture of orange peel.....	1 minim.
Tincture of acacia.....	1 minim.

Two or three to be taken at bedtime.

Concerning the hot-air treatment the writer believes that in the early stages of osteoarthritis the applications lead to increased mobility, but in advanced cases comparatively little benefit ensues. Massage, if performed with care and moderation, may cause some improvement. The combination of massage with the use of hot baths, as carried out for instance at Aix-les-Bains, is sometimes productive of considerable benefit. In the early stages the writer has seen much benefit follow the application of iodine, with repeated gentle, passive movement. The ointment of cadmium iodid (62 grains of cadmium iodid with 1 ounce of simple ointment) has occasionally appeared to give much relief, though sometimes it has caused blistering.

Fetid Bronchitis.—Parcellé (*Progres Médical*, June 16, 1900) recommends the following pill:

R.—Acetate of lead.....	2½ grains.
Terpine hydrate.....	2½ grains.
Dover's powder.....	1½ grains.

Three to four pills daily.

Application for Herpes Zoster.—Bleuler (*Nouveaux Remèdes*, No. 1, 1900) reports 23 cases of herpes zoster in which he employed successfully the following ointment spread upon linen:

R.—Cocain hydrochlorate.....	1 part.
Lanolin.....	50 parts.
Cosmolin.....	50 parts.

According to the writer the subjective pains are relieved at once and the disease brought to a speedy termination.

Gelatin in Hematuria.—Schwabe (*Therapeutische Monatshefte*, June, 1900), reports a case of hematuria in a patient with recurrent nephritis in which he employed without success the usual hemostatic remedies. Prompt and permanent relief, however, was obtained by the injection into each infraclavicular region of 7 drams of physiologic salt-solution containing 2% of pure gelatin, followed by the daily internal administration for a week of a pint of 10% gelatin solution. According to the author the pain was not intense and no unfavorable after-effects were observed.

A Lotion for the Night-Sweats of Phthisis.—Kohnstamm (*Wiener medizinische Blätter*, June 21, 1900) states that the following lotion is very efficient in the night-sweats of phthisis:

R.—Balsam of Peru.....	1 part.
Formic acid.....	5 parts.
Chloral hydrate.....	5 parts.
Trichloroacetic acid.....	1 part.
Absolute alcohol.....	100 parts.

Quinin in Syphilis.—Murray (*Rough Notes on Remedies*) in discussing the treatment of those cases of syphilis which do not respond to mercury or iodids writes: "Happily there is another drug which seems to deal with this mercurio-syphilitic diathesis and to help the patient over the stile, and that is **quinin**. At this juncture a bold administration of quinin will often act like a charm, and it may be safely combined with potassium iodid if that be deemed wise or necessary. This combination seems to be a deadly foe to the mercurio-syphilitic diathesis. Five or six grains of quinin 3 times a day is enough, and it will work well with 15-gr. doses of iodid. Indeed, it is quite wonderful to see how much better the iodid works with quinin than mercury, and how this combination tends to undo the bad effects of mercury where specific disease has occurred in a poor habit of body with unfavorable surroundings."

Prostatic Hypertrophy.—The *Revue Médicale*, July 18, 1900, recommends the following suppositories:

R.—Ammonium sulphoichthyolate.....	5 to 12 grains.
Cacao butter.....	54 grains.

For one suppository.

Opium in the Summer Diarrheas of Children.—Crandall (*International Medical Magazine*, July, 1900) believes that opium, if skilfully used, is capable of doing good in summer diarrhea. He believes that it is contraindicated in the first stages of acute diarrhea before the intestinal canal has been free from decomposing matter; when the passages are infrequent or of bad odor; when there is high temperature or cerebral symptoms are present; when its use is followed by elevation of temperature or the passages become more offensive. It is indicated when the passages are very frequent, with pain; when the passages are excessively frequent, large, and watery; in dysenteric diarrhea, preceded by castor oil or a saline; in late stages, with small, frequent, nagging passages; when the passages consist largely of undigested food, and the bowels act as soon as food is taken into the stomach. Opium should be given alone, so that its dose can be regulated with more certainty. The intervals between its administration should rarely be less than 3 hours, while 4 hours is more commonly advantageous. The dose should be as small as possible. Narcotism should be strictly avoided. The most available preparations for young children are paregoric and the deodorized tincture. The dose of paregoric may be as follows: at 3 months, 2 minims; 1 year, 8 minims; 5 years, 30 minims. The dose of the deodorized tincture may be at 3 months, ⅓ minim; 1 year, ⅓ minim; 5 years, 2 minims.

Original Articles.

MULTIPLE METASTATIC SARCOMATA OF THE LUNGS.

Secondary to Sarcoma of the Right Forearm. Adhesive and Hemorrhagic Pleurisy; Thrombosis of the Pulmonary Artery, with a Necropsy.

By STEPHEN SMITH BURT, A.M., M.D.

Professor of Physical Diagnosis and Clinical Medicine, New York Post-Graduate Medical School and Hospital.

AMONG the patients that have come under my observation during a recent service at the New York Post-Graduate Hospital, there has been an instance of multiple metastatic sarcomata of the lungs which seems to be of enough general interest and importance for publication. "Virchow¹ described sarcomata as new formations of the connective tissue type, distinguishable from the corresponding fully developed tissue by their immaturity, of which the predominance of their cellular elements is a sign." It is stated that "accurate knowledge regarding mediastinal and other intrathoracic tumors dates from a very recent period."

Although pulmonary sarcoma is now a well-recognized disease, it certainly is not of common occurrence; and a metastasis of this neoplasm from the extremities to the lungs is comparatively infrequently encountered.³ "The number of cases coming under the observation of any one observer has always been limited, and opportunity for accurate clinical study of the various forms and of the successive stages is therefore limited." Hence, every additional example of primary sarcoma and its metastases, in view of the necessary paucity of individual experience, should find its way into the public records, for the benefit of those who are especially interested in this subject. Of the 60 examples collated by S. W. Gross to illustrate the pathology of malignant growths, inspection after death disclosed metastatic tumors in 57.14% of the sarcomata. It is not improbable that many of these tumors are discovered for the first time at the autopsy.

In an exhaustive article by W. Roger Williams,⁴ out of 15,481 primary tumors collated, 54.4% were cancers; 9.4% sarcomas; 24.7% nonmalignant tumors; and 11.4% were cysts. Of 1,350 primary sarcomatas tabulated by Williams, 385 were of the bones, and 340 originated in the connective tissue. Of these latter, 11 were found in the mediastinum, 7 in the arm, 5 in the forearm, 18 in the thigh, and 13 in the leg. Out of 385 cases of primary sarcoma of the bones, the humerus was affected 22 times, the radius 3, the ulna 3, the femur 61, the tibia 19, the fibula 11, the clavicle twice, and the ribs 6 times. Among other sources of original growth, the kidney was affected 8, and the lung 3 times. The primary seat of the neoplasm under discussion was in the connective tissue of the right forearm. Williams likewise says that "any given tumor always contains more than a single variety of cell; but in most sarcomata some special variety predominates, and after it the tumor is named. Round-celled and spindle-celled are the commonest, but a mixture in which both these varieties are dominant is of frequent occurrence."

Delafield and Prudden⁵ state that "sarcomata may occur in the liver and lungs, and heart by metastasis, and intimately related as they are to the bloodvessels, metastasis is more apt to occur through the blood than through the lymph-channels, and consequently adja-

cent lymph-glands are much less apt to be invaded than in some other forms of tumor, notably the carcinomata." It will be seen in the following history that there was no involvement of the lymph-glands. "Metastatic deposits are of comparatively rare occurrence in sarcoma," says McGuire.⁶ On the other hand, Dr. N. Senn⁷ asserts that "general dissemination in sarcoma takes place much more frequently, and at an earlier stage than in carcinoma. In this regard sarcoma is much more malignant than carcinoma. The intimate relations which exist between the bloodvessels and the tumor-tissue in sarcoma serve to explain the frequency of metastasis." Inasmuch as the migration of these neoplasms seems to take place by way of the veins, the malignant growth is more prone to reappear in the lungs than elsewhere. Hare⁸ repeats that "it is a point worthy of remark that the lungs very rarely form the starting-point of the growths, and are, indeed, very rarely affected by primary or secondary formations. Ziegler⁹ states "of secondary growths examples of each species of neoplasm that form metastasis at

FIG. 1.—Photomicrograph of spindle-celled sarcoma.

all have been found in the lungs, and, as the tumor grows, reactive inflammation is apt to be set up, especially in the pleura, where it not infrequently assumes a hemorrhagic character, and in the lung the inflammation is usually catarrhal." There was a pronounced catarrhal bronchitis in our patient, together with an inflammation of the pleura that was both adhesive and hemorrhagic. Ziemssen¹⁰ says that "sarcoma is pretty frequently found in the lungs, occurring only secondarily, and generally when the primary seat of the growth is in the bones." In the following case, as previously stated, the original growth involved the connective tissue of the forearm. "Where the disease is primarily in the arm," remarks Hare,¹¹ "the secondary growth is not infrequently in the mediastinum." One singular fact about the case before us was the entire absence of the sarcomatous tumors in the mediastinum. "When the malignant disease extends to the lungs," says Winslow Anderson,¹² "by metastasis from some other organ, the disease is for the most part multiple," and further, "malignant growths of the lungs, like those of all other

organs, tend rapidly to undergo degenerative changes, hence they soon break down and form irregular cavities with considerable hemorrhage." The report of the necropsy will show a breaking down of many of the tumors in this pathological specimen, and the history records a moderate amount of hemoptysis. "Of the varieties of sarcoma the spindle-celled is by far the most common, as it constituted 11 of the 16 cases that have come under my personal observation," declares S. W. Gross," "and it was met with in 45 of the 60 examples that I have collated." The primary tumor was of the large spindle-celled variety in the present instance, and the metastatic tumors were likewise composed of the large spindle cells. In the "Reference Hand-Book of the Medical Sciences" it is stated that "sarcoma is a growth preferably of the first half of life, differing markedly from carcinoma, which is an affection of middle life and of later years." The present patient was 33 years of age. Sarcomatous growths in the lungs exist usually without pain, except in the associated pleurisy, and there was little complaint of pain recorded here, except about the heart, and in the previous history of the attack of pleurisy.

In the *Johns Hopkins Hospital Reports*, Volumes I to VII, there are no cases of multiple metastatic sarcomas of the lungs mentioned. From Volume I, published in 1876, of the "Transactions of the New York Pathological Society" to the last bound volume,

dated 1897-98, but six pulmonary sarcomatous tumors are recorded. The first specimen was presented to the Society by Heitzman in 1876. It was a multiple metastatic round-celled sarcoma of the lung, from the body of a man aged 69, who had had since childhood a primary tumor in the right groin, and who died two years and eight months after the first operation for its removal. The second was an osteosarcoma of the lungs, presented by Van Gieson in 1879, and published in Volume XXX of the *New York Medical Journal*. It was from a man aged 30, and the tumor involved nearly the whole of the left lung, and was strongly adherent

to the chest and pericardium, and involved the apex of the right lung. The third was also presented by Van Gieson in 1887. It was an angiosarcoma of the lung with calcific deposits, removed from the body of a middle-aged woman, who had an amputation of the knee five years previously for a tumor which was not diagnosticated. The fourth was presented by Roosevelt, in 1888, and taken from the body of a boy aged 11, who was brought into the hospital moribund, and who died the day following. It was an extension of a sarcoma from the mediastinum into the left lung. The

fifth was presented by Hodenpyl in 1895, from a man 43 years of age. It was a multiple new growth in the lung, mediastinal and mesenteric glands, liver and stomach, following an injury to the left shoulder resulting in hemorrhagic pleurisy, and thought by Prudden from the description to be both sarcoma and carcinoma. There was about one quart of bloody fluid in the pericardial sac. The sixth was presented by Tuttle, in 1896. It was a specimen of angiosarcoma from a man, 42 years of age, who had primary sarcoma of the kidney with numerous metastatic deposits in the lung and liver, varying from one-fourth of an inch to two inches in diameter.

From 1857 to 1899, comprising Volumes I to XX of the *Proceedings of the Pathological Society of Philadelphia*, there are 9 pulmonary sarcomas recorded. The first specimen, from a man aged 24, was presented by Louis

Starr, and published in Volume IX. There was an intrathoracic tumor of the right side, weighing 10½ pounds, with several calcareous nodules found in the right lung, and two of a similar nature, as large as a filbert, in the left lung. It was secondary to an osteosarcoma of the right femur, for which amputation at the hipjoint was performed, and it was a spindle-celled sarcoma with calcareous and osseous transformations. The patient died 23 months after the operation. The second was presented by H. F. Formad for R. E. Girvin, from a man aged 36, and published in Volume X. It was a secondary multiple sarcoma of the lungs, from

FIG. 2.—Multiple metastatic sarcomata. Left lung.

a small round-celled malignant sarcoma of the left foot, for which there was an amputation at the lower third of the leg, with a reappearance in the lungs three months afterwards. The third was presented by H. M. Fisher, published in Volume XV, from a woman aged 48, and was a small round-celled sarcoma of the mediastinum involving the left lung. The fourth was presented also by H. M. Fisher, from a man aged 25, and published in Volume XVI. It was a multiple sarcoma of the lungs, pleura, heart, etc., secondary to a large round-celled sarcomatous tumor of the rib. There was a hemorrhagic pleurisy. The fifth was

a specimen presented by Alfred Stengel for Thomas Tyson, from a boy aged 13, and published in Volume XVII. It was a multiple round-celled sarcoma of the lung, secondary to sarcoma of the periosteum of the rib. The sixth, also presented by Alfred Stengel, from a boy 7 years old, and published in the same volume, was a primary mixed, small, round-celled and spindle-celled sarcoma of the pleura, or the periosteum of the rib, probably the latter, with secondary involvement of the lungs. The seventh, likewise by Alfred Stengel, from a man aged 38, in the same volume, was an endothelioma primarily in the pleura, with metastasis to the lungs and hemorrhagic pleurisy. The eighth was presented by F. A. Packard, in the same volume, from a woman aged 50, and was a primary endothelioma of the left pleura with secondary involvement of the lung, pericardium and diaphragm. The ninth

was a multile sarcoma, presented by A. O. J. Kelly, and printed in Volume XIX, O. S. It was a metastatic formation from an amputation at the hip for sarcoma of the left femur. The patient was a girl 9 years of age, who died 8 months after the amputation. There were growths in the three mediastinal spaces, the lungs, the pleura, and the brain.

In the bound volumes of the *Boston Medical and Surgical Journal*, from 1886 to 1899, comprising Volumes 115 to 141, there are four cases of intrathoracic sarcoma published. The first, in Volume 120, was an intrathoracic sarcoma, endothelioma, by F. C. Shattuck, from the periosteum of the ribs in a boy of 12. It was

remarkable, as Dr. Shattuck states, for an entire absence of any metastasis. The second, in Volume 131, also by F. C. Shattuck, was a rapid sarcomatosis, in a man aged 36, involving the surface and viscera, including the lungs, but not multiple metastatic sarcomata. The third, in Volume 140, published by George W. Sears, was a primary sarcoma of the posterior mediastinum, involving the lungs, the pleura and the liver, in a man 25 years of age. It was a spindle-celled sarcoma; there was hemorrhagic pleurisy. The fourth, also in Volume 140, by W. F. Whitney, was a large round-celled sarcoma, in a man 39 years of age, of the mediastinum.

There was no metastasis. The growth was by direct extension, and it was restricted to the right side of the pericardium, the right side of the heart, and to the left lung, and the diaphragm on that side.

The examples which have been gathered from the Transactions of the Pathological Societies of New York and Philadelphia, and from the *Boston Medical and Surgical Journal*, number, including my own, 20. Of these, one started primarily in the groin; one in the leg; one in the kidney; one in the lung; four in the mediastinum; two in the pleura; one in the right femur; one in the left femur; one in the left foot; four in the ribs; one in the right forearm; one in the left shoulder; and one apparently was general, rather than local, from the beginning. Sixteen were male and four were females. The ages were: One "middle-aged;" two, 36; two, 25; and one, 7, 9, 11, 12, 13, 24, 30, 33, 38,

39, 42, 43, 48, 50, and 69, respectively. There were six round-celled; two spindle-celled; two angiosarcoma; three endothelioma; one osteosarcoma; one sarcoma and carcinoma; one mixed—small round and spindle-celled; one spindle-celled, with calcareous and osseous transformation; and the nature of three was not given. Finally, there were one hemorrhagic pericarditis, and five hemorrhagic pleurisies among the 20 cases enumerated.

History.—William E. F., admitted to surgical division, July 23, 1899, readmitted to medical division, December 26, 1899, aged 33, married. Occupation, locomotive fireman. Family history negative. Previous history—had the diseases com-

FIG. 3.—Multiple metastatic sarcomata. Right lung.

mon to childhood—measles, whooping-cough, etc.,—also typhoid fever and pneumonia. Four years previous to admission he first noticed a small tumor situated in his right forearm, which then was painless. This tumor gradually increased in size, and finally became sharply painful upon exertion. One year ago, from July 23, he had the tumor removed, but before the wound had healed the growth reappeared, and has been gradually growing larger, and during the past two months more painful. When he entered the surgical division there was a physical examination of the heart and lungs with negative results. The urine was 1.025 in specific gravity; acid in reaction; contained neither albumin nor sugar, and but a few hyaline casts. A second examination of the urine on July 25, revealed neither casts, sugar, nor albumin. There was a tumor on the inner side of the right forearm, five by four inches in diameter, somewhat movable, nodular, with fluctuation in one of the nodules, and encapsulated. A specimen of the neoplasm sent to the laboratory was found by Dr. H. T. Brooks to be a large spindle-celled sarcoma upon microscopic examination. On July 24, 1899, the arm was taken off at the upper third by Dr. W. O. Plympton; the patient made a good recovery, and on August 5, 1899, was discharged from the hospital.

Pathological examination by Dr. R. L. Loughran of the house staff: There is a tumor $2\frac{1}{2} \times 2$ inches in diameter beneath the common tendon of the flexor muscles of the forearm, just below the elbow, and in front of the internal intermuscular septum. This growth extends downwards to within a few inches of the wrist, between the flexor sublimis and extensor carpi ulnaris, becoming thinner as it descends. There is no evidence of the involvement of bone, nor, above the elbow, of the muscles.

The man, after the amputation, continued in apparent good health until the middle of November, when, after retiring one night feeling as well as usual, he awakened next morning to find that he could not get up. He complained of severe, sharp pain in the right side on respiration. A week later he was taken with shortness of breath, which has gradually increased. On December 1st there was pain on the left side in front. An aspirating needle was inserted in the right side of his chest before he returned to the hospital, but only a small amount of blood was withdrawn. On readmission to the hospital his chief complaint was weakness and dyspnea. Temperature 98° F.; pulse 112; respiration 38. Examination of urine December 27, specific gravity, 1.025; reaction, acid; color, amber; transparency, clear. Chemical analysis—albumin, very slight trace; sugar, negative. Microscopic examination—no casts. Second examination, January 10, with similar results, and a few coarse, granular and hyaline casts in addition. Examination of sputa for tubercle-bacilli, with negative results.

Exploration of the chest.—Heart, inspection, no visible cardiac impulse; palpation, impulse of heart against chest wall absent; percussion, flatness from below upwards to the third intercostal space, in the left parasternal line, and dulness thence to the second intercostal space. Flatness extending across and about three-quarters of an inch to the right of the sternum. Flatness extending four inches beyond the left edge of the sternum, and dulness one inch further. Auscultation, heart-sounds almost inaudible.

Lungs, right side, inspection, lack of mobility; palpation, absence of fremitus over the greater part in front and behind; mensuration, no increase in the semi-circumference. Percussion, marked dulness over the upper part, and flatness below, especially behind; auscultation, vesicular respiration heard from above downward with diminished intensity, but rather harsh in quality, to the lower part in front and behind. Left side, inspection, lack of free mobility; palpation, negative; mensuration, negative; percussion,

dulness below in front, vesiculo-tympanic resonance behind; auscultation, fine crackling, and subcrepitant rales lower portion behind. Also a small area of bronchial breathing just below the inferior angle of the scapula; sibilant and sonorous breathing in front and behind, especially behind. The bronchial breathing and subcrepitant rales remained constant throughout subsequent repeated examinations, and were, of course, more distinct during the absence of the sonorous breathing, which was not constant. The bronchial breathing, subcrepitant and fine crackling rales were similar to the combination termed *rale redux* heard in resolving pneumonia. On January 10, the flatness over the cardiac area had disappeared, and the heart-sounds, though not strong, were stronger and decidedly more

FIG. 4.—Multiple metastatic sarcomata. Left lung.

audible than on previous examinations. In other words, the effusion in the pericardium virtually had been reabsorbed.

Clinical notes.—There was practically no fever; the temperature, once reaching 101° F., and once descending to 96.6° F., ranged the remainder of the time between normal and subnormal. Respirations varied from 24 to 40, reaching 50 once, but not often exceeding 36 per minute. The pulse was always rapid and generally weak. There is a record of attacks of coughing, and at first of vomiting; pain in the right shoulder and about the heart; bloody expectoration; restlessness, insomnia, and above all dyspnea; in the beginning appetite fairly good; repeated spitting of blood; profuse night-sweats; almost constant oppression of breathing, temporarily relieved by treatment. It was neither the rapid breathing of acute pneumonia, nor yet of capillary bronchitis, but rather of a gasping type that was comparatively slow and variable, but nevertheless unendurable. There was little, if any, cyanosis; there was pallor, but with flushed

cheeks; his dyspnea very soon resulted in orthopnea; he sat up, or reclined, in a chair most of the time, day and night. He frequently exclaimed, that if he could only get his breath, and a good night's rest, he would be all right. Indeed, his fortitude and cheerfulness throughout were remarkable. There was no enlargement of the superficial glands; there was no malignant cachexia; and he remained fairly well nourished. On January 9, the feet and ankles were much swollen, and were very tender and painful. There were still severe pains about the heart, and distressing attacks of dyspnea. On January 18, still the same complaint. His legs and feet still swollen (edematous) but no longer painful. On January 31, breathing very difficult; appetite gone completely. February 3, awoke in a sort of stupor, and talked aloud to himself almost continually. Short spells of apparent unconsciousness. Died February 4, 1900.

The diagnosis was adherent pleurisy, pericardial effusion, bronchitis, emphysema, asthma, and, eventually, metastatic sarcomata of the lungs, and, finally, pulmonary thrombosis.

At first the more manifest signs of pleurisy, pericardial effusion, and bronchitis with asthma and emphysema appeared quite sufficient to account for all the symptoms. But later, upon the disappearance of the effusion from the pericardial sac, and during the absence of the asthmatic seizures, though the action of the heart had grown somewhat stronger, there were, nevertheless, persistent weakness and orthopnea to be explained. There was no evidence of pressure upon the trachea, esophagus, recurrent laryngeal nerve, nor sympathetic. There was no involvement of the carotid or subclavian arteries. But there were, and had been for some time, symptoms of pressure upon the large veins. Despite the vesiculo-tympanic resonance on the left side behind, which indicated emphysema and masked the dulness; and, allowing for the manifest impossibility of differentiating an adherent pleura, with clotted blood on the right side from a pulmonary sarcomatous infiltration, I finally came, perhaps with more deliberation than was consistent with the circumstances, to the conclusion that the evidence was sufficient for what I had latterly been seeking to demonstrate, namely, a metastatic deposit in the lungs, because of the dulness in front on the left side, and the continuous bronchial breathing behind, together with the subnormal temperature and persistent orthopnea among other symptoms, and the history of the primary sarcoma whereof I had not been unmindful.

It is regrettable that no examination of the sputa was made, except for tubercle-bacilli. From the physical signs I concluded that the pleurisy was plastic chiefly, which it proved to be, and therefore no attempt was made to draw fluid from the pleural cavity, consequently there was no microscopical examination of the clot which occupied the space in the pleural sac that remained. In regard to the diagnosis of pulmonary thrombosis, it simply may be said that the picture of such an occurrence was still vividly in my mind when its re-presentation appeared in this case towards its termination. The apparently increased distress of the breathing; the swelling of the superficial veins; the livid countenance; the increase of the anasarca; the repeated reference to the heart; the irregularity of its action; the tumultuous, and, withal, weakness of its impulse; the failing distinctness of the heart-sounds, with, at the same time, a certain discrepancy between respirations that were fairly deep for him, and reiterated complaints of air-hunger such as occur in cardiac dyspnea; all this, as said in the beginning, was a reproduction of a former scene wherein pulmonary thrombosis was taking place; hence, my diagnosis.

Respecting the treatment, the patient was given, among other drugs, digitalis, strychnia, nitroglycerin, and compound spirits of ether. Hoffman's anodyne proved of no relief to the dyspnea, but extensive and daily dry cupping chiefly, with now and then hot flaxseed and mustard poultices, and, finally, oxygen inhalations, were a great and continued source of relief and comfort, supplemented by small doses of atropia and morphia hypodermically.

Report of Necropsy.—February 6, 1900. Necropsy on the body of William E. F., performed by Dr. H. A. Gribbon, of the house staff, under the direction of Dr. Henry Turner Brooks, pathologist.

General Conditions.—Body well nourished; right arm shows old amputation about six inches below the shoulder; stump normal; rigor mortis pronounced; postmortem congestion of the most dependent parts; moderate amount of anasarca; abdominal fat about one quarter of an inch thick; costal cartilages not calcified; on removal of sternum, lungs bulge forward, color black mottled.

Lungs.—Right lung, surface irregularly nodular; nodules vary in size from one quarter to two inches in diameter; consistence of lung boggy adherent to chest-wall all over the anterior and lateral surface; small area behind not adherent; separation is made with difficulty; large clot of blood in the pleural cavity; blood partially organized and intimately connected with lung-parenchyma and ribs; further separation tears lung-tissue, leaving fragments adhering to the costal cartilages and the ribs; whole substance of lung soaked with bloody liquid; section through nodules shows some of them to consist of a soft mass closely resembling blood-clot; some show blood-clot center with small periphery of soft, white tissue; some show solid white mass with occasional blood foci, others show pure white, or yellow white, bacon-like appearance; section through lungs shows these nodules distributed throughout. The left lung separates readily from pleural adhesions, and shows one very large irregularly lobulated nodule occupying the lower part of the upper lobe, and almost the entire lower lobe near the front; section through this growth shows soft, white encephaloid tissue. The lung also contains several small nodules, mostly with softened blood-mass centers. Behind there was hypostatic congestion; lower lobe behind also shows pronounced emphysema; section shows large dilated alveoli—spongy appearance. Trachea and bronchi down to the smallest branches intensely congested, mucosa brilliant red and covered with bloody mucus.

Pericardium.—Thin, smooth and glistening; sac contains about two ounces of clear sanguinolent fluid.

Heart.—Displaced to the right; normal in size; muscles show slight fatty and interstitial change; right auricle filled with dark clot. Pulmonary artery filled with dark clot partly decolorized, and of sufficient consistency to be drawn out in its entirety.

Liver.—Slightly enlarged; extends one and a half inches below the free border of the ribs; surface smooth; color dark red with slight mottling—nutmeg liver; on section, shows fatty change associated with passive congestion.

Kidneys.—Large, dark red; capsule strips off with difficulty, leaving granular surface; on section, cortex swollen, alternate yellow and red cortical markings; pyramids passively congested; whole kidney shows slight fatty and interstitial change. Diagnosis, chronic diffuse nephritis.

Spleen.—Slightly enlarged, soft; on section, dark and granular; parenchyma—soft and easily scraped off.

Brain, stomach, intestines, and pancreas not examined. No evidence of any lymphatic enlargement; no metastatic deposits elsewhere than in the lungs. Microscopic examination of the neoplasm shows it to be a large spindle-celled sarcoma.

GYNECOLOGY, ITS PRESENT, PAST, AND FUTURE.¹

By HOWARD A. KELLY, M.D.,

of Baltimore, Md.

IN extending me the distinguished honor of your invitation this evening I clearly recognize the fact that you have wished to acknowledge the present prominence of the special branch of surgery to which it is my good fortune to have devoted the working years of my life, rather than to exalt an individual who is merely one of the army of toilers who are busy in all the various branches of an art erecting the coralline structure in which we dwell so happily together.

Most appropriate, therefore, has it seemed to me to consider with you for a few brief moments the relationship of that not very euphonistically named branch, gynecology, to the greater fields of general medicine and surgery. Could I by the issuance of a mandate compel each one here present to declare instantaneously what he understands by the term "gynecology," I think you would one and all affirm that gynecology constitutes a well-defined branch of medical science, a crystallized entity, handed down from our forefathers, for which perhaps the present generation has furnished some accretions, a branch including within its scope all those diseases which are peculiar to women.

You would also quite surely tell me that while this has been, and is its field, you fully expected it to continue to operate within the same lines in the future.

If, however, I allow you a little time for reflection you will be inclined, I am sure, to modify your definition somewhat, perhaps recalling first the fact that "gynecology" is a term of widely varying significance in various localities. In Germany the leaders in gynecology, the professors in the various universities, are of necessity great obstetrical teachers as well, and find in the efficient conducting of the two chairs, in practice and in didactics, about as much work as one man can well compass.

In our own land the divorcement between gynecology and obstetrics has been long since effected through the absorbing activity of the more active surgical specialty, and with one important arm thus set free the gynecologist has reached out in other directions, and has sought to make good his loss by adding to his territory various kindred abdominal operations. There is, therefore, today a broad undefined zone in which both the gynecologist and the general surgeon are alike active.

You will, too, perhaps recall the fact that by way of compensation, or I might say in anticipation of these inroads, the general surgeon has recouped himself *prenumerando*, by laying hold of the whole range of breast affections which are peculiarly gynecologic (*sensu strictissimo*). I may, however, well pause to add in parentheses that I consider that this great act of trespass has been fortunate indeed for humanity, and I bear no grudge when I witness for example, as is often my pleasure, the wonderfully improved results of Halsted's breast operations.

While the gynecologist has thus been advancing his

domain in an upward direction, owing to the improvements in general technic and the greater precision of our various gynecologic operations easily described and for the most part easily imitated, our confrères have been no less busy in extending their own field downward, and herein lies a little source of occasional complaint and of some slight irritation, manifested only when we forget for a time the breadth and the magnanimity which should characterize lives weighted with so great and such sacred responsibilities.

To this matter and to its solution I shall recur again.

If the gynecology of today is such a variable conception, a thing of such mobile equilibrium, what of that of the past? Are the trespassers of this generation indeed guilty of that offence most heinous in the eyes of mankind, the shattering of a time-honored hoary idol? The rootlets of gynecology reach back, it is true, into a hoar antiquity (speaking as mortals speak), and the zealous historian finds precise and precious data in all the early writings, and especially in those of Soranus and of Celsus of the first century.

Then, again, after the curtain of the black night which fell over first the Greek and then the Arabian copyists, Aëtius, Rufus, Oribasius, Avicenna, Rhazes, and Abulcasis, was lifted the first glimpse of the dawn of the mighty day was shed in the middle of the fifteen hundreds by the anatomy of Vesalius (1543) and the surgery of Ambroise Paré, to be followed at once by the large collective gynecologic work of Casper Baulein, of Basel, reëdited toward the end of the century in a great volume by Israel Spach. But these "Gyneciorum libri," or gynecologies, were but the collated observations of the ancients and constituted the evidence of no specialty, for there were no men giving exclusive attention to the branch and there was no science.

But from now on, beginning with Felix Plater, Rousset's hysterotomotoky, Roonhuysen, Fatio, Levret, Naegele, and a host of others for the next two hundred years, observations began to accumulate and the first foundation-stones were laid, although even yet no specialty existed, nor was it born until the second quarter of this century in which we live.

Then the great superstructure in which we dwell was erected by the giant labors of a few men working in different but kindred fields, and it is by the gathering together into one these converging lines the science of gynecology as we understand it today has been formed.

If I may erect a circle of honor with gynecology on a pedestal in the center, I will place in the periphery of the circle all pointing to the common center, the figures of MacDowell, who gave us ovariectomy; of Jobert de Lamballe; of Sims and of Simon, whose joint labors rescued vesicovaginal fistula from the list of impracticable procedures; of Atlee and Keith, who labored so bravely in operating upon fibroid tumors. I would give a position of preeminent excellence to Virchow, whose cellular pathology is the very groundwork of all that is scientific in our work. I would place T. A. Emmet there for his undying services in the domain of plastic surgery.

I would give Lord Lister a place beside Virchow as the greatest conservator of life the surgical world has ever known.

And so on, time would fail me should I attempt to mention the mighty Blundell, Simpson, Pean, Koeberlé, Hegar, Martin, and the whole galaxy of other great German and brilliant French investigators whose labors are our common property today.

And so it is, you see, if I may change my figure, by

the blending or the flowing together of these streams that the mighty current is made on which we are so satisfactorily borne today. Not without many eddies and counter-currents did these streams come together; and so we see that like general medicine, our branch has passed through her fads, and although but a creature of the latest century, she is, after all, a little microcism exhibiting the spirit which has energized the whole.

We have lived through our cervical catarrh and ulceration era, when these notions dominated all our pathology, and therefore our therapeutics, like the humoralist doctrines of old. We have seen the day when vesico-vaginal fistulae fixed the attention of the world as a crowning surgical achievement. We have witnessed ante- and retroflexions, the great dominating factors in our pathology and the innocent inspirers of the vast horde of pessaries. We have watched the rise and fall of pelvic cellulitis.

We have then seen pelvic peritonitis and pelvic abscess assume the prominent role.

Again, extrauterine pregnancy in the hands of Tait came like a great refreshing discovery to taking the place of pelvic hematoceles, inspiring a mass of literature which no man can digest.

Hysterectomy for cancer and hysterectomy for fibroid tumors then came to the front as a godsend to thousands of hopeless sufferers.

And still the march goes on; diseases of the appendix and other great problems in abdominal surgery have been added to the list. Diseases of the urinary tract are destined in the immediate future to attract our most interested attention, and if I am not wrong in my forecast, a better understanding of diseases of the rectum will follow, and I would add to the list, the as yet vaguely understood affections of the gallbladder. Let them go on until the tale is complete and until we have reached the acme of our art under its present limitations; until some mighty mind reveals some new principle which will revolutionize and reorganize all our work on new lines.

But what of the immediate future of gynecology? Unless I wrongly read the signs of the times, and unless I would shun what seems to me to be an irresistible conclusion, the future of gynecology is destined to develop a closer association with the parent trunk from which she was originally broken off; the aims of gynecology and of general surgery are one. Gynecology is, after all, but a branch of general surgery, to be cultivated by reason of predilection and of special aptitude, but, after all, one of the branches.

I take it that from now on the interests of humanity will be best served by discouraging the training of men as gynecologists exclusively, and by insisting upon the broad training of general surgery as the best equipment to do this work in the best possible way.

THE CHEMICAL EXAMINATION OF FECES FOR CLINICAL PURPOSES.

By A. E. AUSTIN, A.M., M.D.

of Boston, Mass.

From the Chemical Laboratory of Tufts College Medical School.

THE examination of feces has received, as is well known, too little attention from physicians, probably for various reasons. First, on account of the disagreeable nature of the manipulations required; second,

from a disinclination of the patient to provide such means of diagnosis; and third, because up to the present time we have been unable to derive from such examinations the positive results which we desire and also expect. Notwithstanding these obstacles, however, it seems that we ought to continue such investigations, simply because we wish to perfect the results obtained from such means. From such examinations several points can be learned. First, in regard to the pancreas with its threefold function of fat-splitting, albumen-converting, and saccharification; second, by this means we learn the rapidity and completeness of absorption of the digestive products in the digestive tract; third, the motility of the intestines; and fourth, the nature of the fermentative processes which take place there.

The objections to collection and manipulation may be largely avoided by the use of weighed Mason jars which are given to the patient and in which are to be collected the 24 hours' feces. These, when again weighed, less the original weight of the jar, will give the weight of the feces in their moist state. When such feces are more carefully examined, they are found to consist of three elements: first, the undigested elements of food; second, side-products produced during the course of digestion; and third, constituents arising from the secretions and excretions of the intestinal mucous membrane. It is a well-known fact that during fasting, feces are still formed from the cast-off epithelium of the intestines, a fact which has been substantiated by Hermann.¹ The composition of the feces varies also according to the nature of the food, there being more after vegetable food, and less after animal food. Voit² found in 24 hours after mixed food, 120 to 150 grams of feces, with 30 to 37 grams solid residue; after vegetable food, 333 grams, with 75 grams solid residue.

The commonest constituents are muscle-fibers, connective tissue, particles of casein, starch, fat, cellulose, and nuclein. All of these come from the food. From the excretions, on the other hand, and the mucous membrane producing them, there are found mucin, cholic acid and cholesterin; while from the products of decomposition we find skatol, indol and fatty acids, especially acetic acid, calcium and magnesium soaps. We find no chlorids; because of their ready solubility they are absorbed and eliminated in the urine. The insoluble ammonium magnesium phosphate is quite common, however, and can be readily detected by the microscope by its peculiar coffin-lid shape. The neutral calcium phosphate and magnesium phosphate are found, coming chiefly from the food. Bacteria in great numbers, together with stercobilin, are found, but no bilirubin or biliverdin unless there is present undue motility.

Microscopic Analysis.—With the microscopic analysis, in my estimation, but little is to be learned. It is true that muscle-fibers may be found, but these are always found when a largely meat diet is taken, and the only inference which can be derived is very clearly stated in the following statement taken from Nothnagel:³ "When there is no fever, but symptoms point to existing catarrh of the intestinal tract (mucous), and large numbers of muscle-fibers are found, then only can we reach a reasonable conclusion that catarrh of the small intestine exists." Boas⁴ declares strongly against the view that such an abundance of muscle-fibers means an affection of the pancreas, as Friedreich states. The presence of starch granules under the microscope, which can also be confirmed by the addition of iodine in iodid

of potash solution, does not of necessity mean an impaired pancreatic digestion, but may mean an increased motility, by which the intestinal contents are hurried out before absorption can take place. These, however, are extremely rare—rarer even than muscle-fibers or fat-globules. Of the latter we may say that they may be present in quite considerable numbers, either as aggregations of needle-like crystals, more or less curved, due to the presence of fatty acids, or as longer and straighter needles, frequently arranged in groups, due to the presence of soaps of magnesium or calcium. It is possible also to find both neutral fats and soaps in the form of globules. A distinction can be readily made by warming the slide; the neutral fats and fatty acids are converted into globules, the soaps remain permanent. Then, of course, with the microscope, we can also find clumps of casein in the feces of small children, where the diet consists principally of milk. The great disadvantage of these microscopic methods is that we cannot get any quantitative idea of these ingredients present, and these quantitative amounts only can give us an idea of the degree of digestion, absorption, etc.

Chemical Analysis.—The importance of examining quantitatively the stomach-contents, or rather the gastric juice, for the purpose of diagnosis, has so impressed itself upon the minds of physicians, that at present few attempt to treat such disorders without a quantitative examination. The question presents itself to us at the present time—Why cannot we make an analogous examination of the feces? because unquestionably we have intestinal indigestion as well as gastric indigestion, and the results seem to be far more serious. The repeated removal of the stomach and continued health of the patient have shown that we can live very comfortably without the stomach, and without marked emaciation from the failure of this part of digestion. All experiments, however, which have had for their object the removal of the pancreas, have convinced us of the untoward symptoms which arise from such a removal. Persistent diabetes, very limited utilization of food, and marked emaciation have invariably followed. We can also, from a clinical point of view, appreciate the rapid emaciation which follows disease of the pancreas. It was only within the last year that we have had evidence that such removal of the pancreas for suppurative disease (Richardson) can be followed by fair health and good digestion. The only practical means of demonstrating the changed character of digestion when the pancreas is impaired or removed, is the examination of the products left unabsorbed after such digestion. This, of course, can only be obtained from the feces-examination. The method of obtaining pancreatic juice by the introduction of a tube through the duodenum into the pyloric orifice, has proved impracticable, though attempted by Ewald, Boas, and others. The examination of feces after extirpation of the pancreas in animals, and disease of the same in man, has shown some curious results. Ablemann and Minkowski⁵ found only 44% of the albumen taken, absorbed; of the carbohydrates only 57 to 61%, and of the fat none. Later, however, Mueller found that in a case of complete closure of the pancreatic duct, verified by autopsy, there was a perfect digestion of starch, and that fat digestion suffered to no great extent. This is probably due to the fact that the neutral fats are split up into fatty acid and glycerin by means of the bacteria in the intestine. In order to demonstrate the digestive power of the pan-

creatic juice, it is necessary to determine separately the fat, starch, and nitrogen in the feces on account of the former's threefold function, since it would seem improbable that all three functions would suffer to an equal extent. It is also possible that mental disturbances may have the same influence upon the pancreatic digestion that it has upon stomach-digestion. This influence, as we know, is generally directed toward the secretions of hydrochloric acid, and does not act upon the secretion of pepsin. The examination of feces, however, without a knowledge of the nature of the diet, would be practically worthless, yet it would seem that there is no objection to giving a test-meal or series of test-meals, in which the respective amounts of fat, starch, and albumen are known, and from which direct comparison can be made between these elements taken, and eliminated undigested in the feces. Such a day's ration is suggested in the following composition:

430 grams (15 oz.) pea meal.

200 grams (7 oz.) rice flour.

113.4 grams (4 oz.) butter.

This can be made into a loaf or into crackers and corresponds in terms of these three elements to 116 grams of albumen, 113.2 grams fat, and 384 grams carbohydrates, the proportions which will give about the average daily food as required by the need of an ordinary man, which, according to Voit, consists of 100 grams albumen, 100 grams fat, and 400 grams carbohydrates. Or there is a form of food known as the diabetic cracker, sold by the Health Food Company, which contains, according to the analysis made by me, 9.4% albumen, 53.4% carbohydrates with no free sugar, and 8.5% fat. One thousand grams of this taken every 24 hours, as can be readily seen, would give 94 grams albumen, 534 grams carbohydrates, and 85 grams fat. This daily ration could either be preceded the night before with a laxative, or there could be taken with the first portion .3 gram carmine, which would stain the feces and indicate when the first residue from this ration appeared in the feces.

To return to the feces, absolute accuracy is of course desirable, but yet we can weigh the 24 hours' feces, and then determine in aliquot parts the amount of N substances, fat and carbohydrate and calculate for the 24 hours' feces as is done in urine. This theoretically should give some information as to which of the pancreatic functions, if either, is wanting; or if we found these undigested substances alike increased, we could either say that all the functions were lacking, or that there was an increased motility which prevented complete absorption. In the latter case, we could easily demonstrate this by determining whether albumose, peptone, or sugar was present,—substances equally indicative of wanting absorptive power. It is always advisable to weigh out two portions of 5 grams each, which shall serve respectively for the determination of carbohydrates and fat, and one portion of 1 gram which shall serve for nitrogenous estimation by Kjeldahl's method. The portion reserved for the determination of fat must of necessity be dried, and we can also combine a determination of the amount of water by drying it in a weighed dish accompanied by a weighed rod. The process of drying is always a long and tedious one, but can be hastened by mixing this portion of the feces with absolute alcohol (50 cc.), and after this has been driven off, another portion of 25 cc. is added and evaporated, whereupon the feces generally form a dried, easily powdered mass, especially adapted to

extraction with the Soxhlet apparatus which is generally employed. This process will not remove the fat present as soap, but this can be easily obviated by adding a few drops of any acid to the alcohol, which splits up the soap and allows the fatty acids to be extracted by the subsequent treatment by ether. If it is desirable to determine the fatty acids separately, the extracted combined fat may be dissolved in a mixture of ether and alcohol, and titrated with $\frac{1}{10}$ normal NaOH solution in alcohol with phenolphthalein as an indicator. That portion which is intended for the determination of the carbohydrates is to be cooked for an hour or two with 100 cc. of 25% H_2SO_4 , filtered and then alkalinized. The volume of 100 is reestablished by the addition of water, and the sugar (resulting from the converted starch and cellulose) determined; the original carbohydrates will be equal to .9 of the sugar found. We now have a determination of the water, residual albumin (calculated from N by factor 6.25), fat and the carbohydrates (calculated from sugar).

It is also important, from the quantitative point of view, to mix a large portion of the feces, 50 grams at least, with water, and distill over the skatol and indol, the respective amounts of which would demonstrate even better than the ethereal sulphates in urine, the bacterial fermentation taking place in the intestines and the amount of autointoxication going on. Before important inferences can be drawn from such analyses, it is first necessary to establish a normal degree of utilization of food. This is excessively difficult, because the form in which the element occurs has great influence upon the amount of it absorbed; for instance, a much larger portion of nitrogen is absorbed in a meat diet than in a diet consisting of cereals, and also the form in which the same food is taken determines to a large extent the absorption. It has been shown that a much larger portion of the carbohydrates of potato is utilized when the potato is mashed than when cut up coarsely as is customary in potato salad. If, however, we establish a distinct form in which the three elements are to be taken as food, it seems possible to compare the results with a moderate degree of accuracy. To cite a few illustrations from Von Noorden's *Pathologie des Stoffwechsels*, we learn that from bread from coarse flour only 2.6% are lost, and that the feces in a condition of normal digestion contain only .5 to 1 gram of N in 24 hours.

This means, upon the above mentioned diet, a loss of 3 to 5%, and the loss of fat amounts to 4 to 6%. The following few cases were given approximately this amount and nature of food, and the feces collected for 24 hours were examined quantitatively.

CASE 1.—This case was from the practice of Dr. F. B. Brown, and was that of a young man complaining of enormous distention of the abdomen with gas. The rumbling from the collection of gases was very annoying, and could be heard by persons in the same room. There was some discomfort from pressure, but otherwise the man was in a normal condition. The feces were found of natural color, and possessed no bile pigments. The amount obtained weighed 132 grams in a moist state. The water was not determined, but the feces were well mixed and percentages were based upon the feces in a moist condition. No particles of mucin were found under the microscope, but there were some muscle-fibers, a few starch granules, and enormous numbers of bacteria. By means of distillation, large quantities of indol and skatol were found, and indican was plentiful in the urine. A quantitative analysis for the 3 chief elements of undigested food showed 5.8% starch, 2.1% nitrogen, and .34% of fats. These percentages, based upon 132 grams of feces,

show that 7.65 grams starch were present, which, based upon consumption of 400 grams, means a loss of 1.9%. Of nitrogen, there was present 2.77 grams, or a loss of 17.3% based on a consumption of 100 grams of albumen, which equals 16 grams nitrogen. There were present 448 milligrams of fat, or .44 of 1% on a basis of 100 gr.

CASE 2.—Also from the practice of Dr. Brown; a woman who had diarrhea and constipation alternately, who was undergoing the climacteric, and in whom no menses had been present for 5 months. She had .1 of 1% of albumin in her urine, with a sediment consisting of pus, oxalate of calcium and pelvic cells. The feces were of a yellowish color, and the 24 hours' amount weighed 127 grams. Albumose and dextrose were both absent. A quantitative analysis, as described above, showed 2.48 grams nitrogen, 689 milligrams of fat, 4.81 grams of carbohydrate, which, based upon the above diet, shows a loss of 15.51% of nitrogen, .69 of 1% of fat, and 1.2% carbohydrate.

CASE 3.—A man who complained of vague distress in the abdomen, but whose movements were regular and normal; 24 hours' feces weighed 119 grams. Quantitative analysis showed 1.66 grams nitrogen, 3.7 grams fat chiefly in the form of fatty acids, while the carbohydrates were present in too small amounts to be estimated. This would give a loss on the above diet of 10.3% of nitrogen, and 3.7% of fat.

For comparison, 2 tables are here appended. One from Von Noorden's *Stoffwechsel* gives results on perfectly normal individuals, prepared by various investigators, and one containing the results of these experiments.

TABLE I.

FOOD.			FECES.		
Nitrogen.	Fat.	Carbo-hydrate.	Nitrogen.	Fat.	Carbo-hydrate.
15.4	95.1		6.5 %	3.3 %	
15.3	94.2		4.8 %	6.9 %	
17.2	80.	154.	5.9 %	5.2 %	
15.782	40.49	289.64	4.6 %	3.4 %	
14.57	156.3	193.	18.9 %	3.27 %	2.79
15.36	227.5	423.7	16.7 %	2.81 %	1.35

TABLE II.

FOOD, APPROXIMATE.			LOSS IN FECES.		
Nitrogen.	Fat.	Carbo-hydrate.	Nitrogen.	Fat.	Carbo-hydrate.
16	100	400	17.3 %	.441 %	1.9 %
16	100	400	15.51 %	.691 %	1.2 %
16	100	400	10.3 %	3.7 %	None.

A short reference to Table I shows a wide variation in the loss under perfectly normal conditions. The amount of fat and carbohydrate unabsorbed remains quite constant, while the amount of nitrogen shows the widest differences, varying from 4.6 to 16.7% of loss. This must be due to a failure of digestion and not to absorption, because these experimentors state that no albumose-peptone was found in the feces. In the examination made by me, likewise, no albumose-peptone was found. There is present a strong possibility that the excessively acid condition of the stomach contents when poured into the duodenum may inhibit to a certain extent the action of trypsin upon the contents, which is also true of amylaceous digestion. The absorption of carbohydrate when digested is most excellent, dextrose being one of the rarest of substances found in the feces. It is possible that a large amount of the carbohydrate found arises from the cellulose in the food which is practically incapable of digestion, except by means of the bacteria which infest the in-

testinal tract in such large numbers. In cases where fat is found, it is very desirable to determine the nature of the fat, whether it exists as fatty acid, soaps, or neutral fats, because upon this is based the differentiation of faulty digestion or faulty absorption. The former means the absence of pancreatic juice under the conditions mentioned above, while the latter means the absence of bile. From this, we can conclude with fair certainty whether the pancreas or the liver is diseased.

Bile.—The normal feces always contain stercobilin, an analogous substance to urobilin, but never biliverdin or bilirubin, unless there is a catarrhal condition of the duodenum, with associated increased motility. Schmidt has devised a very simple and satisfactory means of distinguishing the biliary coloring-matters from the stercobilin. If we add to the feces a solution of mercuric chlorid a red color shows the presence of stercobilin, a green color the presence of the biliary coloring substances. There are also some interesting cases of what are known as cholic stools with absence of icterus. Unfortunately, as yet, we cannot derive any important diagnostic value from this peculiarity, because it has been found under such varying conditions as leukemia and carcinoma of the intestines, while Nothnagel claims to have found it in certain stages of phthisis. It seems that this condition is not necessarily due to the absence of stercobilin, but to the fact that fat is present in such enormous quantities that the normal color of the feces is obscured.

We have also, as another product of biliary coloring-matters, exceedingly small bodies which correspond to the gravel of urine. One opportunity has been presented to me of examining such feces from a case which had experienced a great deal of pain, but never had had jaundice. These small bodies were of about the size of a head of a pin, and were obtained from the feces by mixing with water, and straining through cheesecloth, and when isolated in this way were found, when examined under a microscope, to be faceted like the ordinary gallstone of greater size. This case, which was in the care of Dr. H. D. Arnold, was afterwards operated on, and on opening the gallbladder, various larger stones were found, which could not pass through the common duct. Chemical examination of these small bodies showed that they consisted of a compound of bilirubin and lime.

Diagnostic.—It is with some disappointment that we review the results which have been obtained from the examination of the feces, and upon referring to those who have had the largest amount of experience in such examinations, we find that they are not at all agreed as to the diagnostic value of certain of these chemical points. For instance, von Jaksch⁶ says that the native albumin can always be found in typhoid-fever feces and in those of diarrhea. He also claims to find albumose under the following varied conditions: Typhoid fever, tuberculous ulcers of the intestines, and peritonitis with purulent discharge into the intestines. He has also found it in scarlet fever, chronic nephritis, and chlorosis. The poor absorption of well-split and well-saponified fat, according to Biedert and Demme, can be found in duodenitis of children, and in tuberculosis of the mesentery glands. Nothnagel finds this condition in intestinal atrophy, amyloid and tuberculous condition of the intestines. The absence of pancreatic juice does not show as great difference as might be expected. There is, however, 40% split and saponified fat instead of 84%, as usually found. The presence

of enzymes, trypsin and amyllopsin, which can be easily demonstrated by allowing a small fragment of blood-fibrin to remain suspended in the liquid feces a few hours, whereupon the enzymes become fairly attached to the blood-fibrin, and their nature determined by their action upon starch or the fibrin itself,—has so far proved of little diagnostic value. About the only inference which can be drawn from their presence is the fact of excessive motility, and this is usually accompanied by catarrhal inflammation of the duodenum.

CHRONIC EAR-VERTIGO (MÉNIÈRE'S DISEASE); ITS MECHANISM AND SURGICAL TREATMENT.¹

By CHARLES H. BURNETT, M.D.,

of Philadelphia.

Aural Surgeon, Presbyterian Hospital, etc.

CHRONIC ear-vertigo, sometimes called Ménière's disease, consists in paroxysmal attacks of vertigo, due primarily to chronic disease in the tympanic cavity. The effects of the chronic disease in the middle ear are conveyed to the semicircular canals in the internal ear and thence reflected to the cerebellum. Chronic ear-vertigo is most frequently caused by chronic catarrh of the middle ear. This latter malady tends to sclerosis of the mucous membrane of the cavity, rigidity of the membrane of the round window, retraction and stiffening of the ossicles of hearing, and a consequent impaction of the stapes in the oval window of the vestibule. This latter event, by pressure upon the labyrinth fluid and consequent compression of the endolymph about the nerve terminals in the ampullae of the semicircular canals, leads to the reflex phenomena termed ear-vertigo.

In order to understand the mechanism of ear-vertigo, one must recall the anatomy of the middle and internal ears.

1. *The Labyrinth Fluid.*—The labyrinth fluid is composed of two systems, viz., the endolymph, that which fills the interior of the membranous labyrinth, and the perilymph filling the cavity of the bony labyrinth, in which the membranous labyrinth is suspended. The endolymph, according to Hasse of Würzburg, comes from an epicerebral lymph-cavity, being conveyed by the so-called aqueductus vestibuli to the cavity of the membranous labyrinth. Every increased or diminished pressure in the cerebrospinal fluid in the subarachnoid cavity will make itself felt through the aqueductus vestibuli in the interior of the membranous labyrinth. The same authority shows that the perilymph is poured into the labyrinth from the subarachnoid space, through the foramina acustica, and leaves the labyrinth by means of the aqueductus cochleae. In fact the perilymphatic cavity is inserted into the lymphatic tract of all vertebrates, and, being in connection with the subarachnoid space, it is seen how changes of any kind in the cerebrospinal fluid can be communicated to the perilymph and thence to the various parts of the mem-

¹ Read at the meeting of the American Otological Society, Congress of American Physicians and Surgeons, Washington, D. C., May 1, 1900.

branous labyrinth. Especially can we understand how easily intralabyrinth fluid-pressure may be increased either from the cranial side through the aqueducts, or the tympanic side through impaction of the stapes in the oval window, the semicircular canals thus irritated, and vertigo ensue.

If in a properly prepared, normal auditory apparatus, in a cadaver, sound is conveyed from an organ pipe into the external ear, the vibrations of the membrana, ossicles, and of the round window membrane can be seen and measured, as I have shown in my physiologic acoustic experiments, in Helmholtz's laboratory in 1871-72. If the auditory apparatus has been so prepared as for the experimenter to be able to convey water to the labyrinth from the side of the cranial cavity and thus increase the intralabyrinth pressure, while the sound vibrations of the ossicles and round-window membrane are going on, he will soon perceive that the intralabyrinth distention or engorgement thus brought about by the introduction of water into the internal ear will force the stapes and round-window membrane tightly outward and cause their vibrations to cease, while the vibrations of the membrana, mal-

H., hammer. I., incus. S., stapes. M.T., membrana tympani. V., vestibule. O.W., oval window. R.W., round window. T., tendon of the tensor tympani.

leus, and incus continue. Thus an idea may be gained of what takes place in an engorgement of the internal ear from influx of lymph from the cranial cavity, or from congestion of the former. This outward fixation of the stapes in such instances might be less if the bonelet were not pushed outward against the incus and its fixation thus further augmented. Outward distention of the round-window membrane could be overcome by puncturing it. But this I have never done.

2. *Scheme of the Middle and Internal Ears in the Mechanism of Ear-Vertigo.*—My meaning as to the mechanism of chronic ear-vertigo may be made clearer by a consideration of Fig. A. Thus, if the stapes, S., is impacted into the oval window, O.W., its footplate will press upon the fluid in the vestibule, V., and if a recoil from this pressure cannot be obtained by the bulging of the membrane of the round window, R.W., towards the tympanic cavity, the lymph in V. as well as in the entire labyrinth is unduly compressed, the semicircular canals irritated, and ear-vertigo results. Or, if in any

sudden and copious influx of lymph from the cranial cavity into the labyrinth, or in an increased vascularity of the labyrinth, a compensating recoil from such intralabyrinth pressure cannot be obtained at R.W., and also at S., as in a normal ear, the semicircular canals are unduly compressed and ear-vertigo is evoked. As is well known, both of these recoil-points in the fenestrae become more or less unyielding in the later stages of chronic catarrh of the middle ear, when paroxysms of ear-vertigo are likely to be added to the already profound deafness and tinnitus.

Symptoms.—As the great majority of cases of chronic ear-vertigo occur in chronic sclerotic otitis media, let us first consider the symptoms of ear-vertigo as they occur in this form of tympanic disease. Usually only one ear, the worse, is the cause of ear-vertigo, though both ears may be affected with so-called chronic catarrhal otitis media. The more affected ear—the one causing the ear-vertigo—is *always profoundly deaf* and may be the seat of distressing tinnitus. In any case, chronic ear-vertigo is (chronologically) the last among the lesions of chronic catarrh of the middle ear. It is manifest that the internal ear can lose its hearing function before its equilibrating function. In an ordinary case of ear-vertigo from chronic tympanic catarrh, the patient in the first attack is seized with a sudden and, to him, unaccountable vertigo, usually attended with an increase of tinnitus in the implicated ear. The attack may last from a few minutes to half an hour. The patient may be obliged to take hold of something for support, or to sit or lie down. Nausea may be present in the early attacks if the vertigo continues as long as fifteen minutes, but as a rule nausea and vomiting do not occur in the first paroxysms of this disease. When the seizures become more frequent, more severe, and longer in duration, nausea and vomiting may be very intense and result in a form of collapse, with pallid face and clammy surface, but without *loss of consciousness*. The fact that the patient does not lose consciousness from ear-vertigo serves as the great differential guide in diagnosis between ear-vertigo and apoplexy and epilepsy, with both of which it is often confounded at first. The apparent motion in ear-vertigo is generally towards the affected ear, in which direction the patient tends to fall. When both ears are the cause of ear-vertigo, the patient is entirely unable to walk, and sits down whenever he is attacked, even in the street. In such cases the patient's actions are often mistakenly attributed to alcoholic intoxication. These phenomena have been termed Ménière's Symptoms, or Disease.

The first attack of ear-vertigo is usually comparatively light and generally attributed to stomache derangement and treated as such. This first attack may not be followed by another for weeks or even months. Then a more severe attack comes on, which is followed in a week or two by another. At last the attacks may occur every week or every day. The patient now fears to leave the house unless accompanied by an attendant, and is forced by this quasi agoraphobia to give up any regular duties outside of his house. Even in such cases the true cause of the ear-vertigo is usually overlooked and the symptoms attributed to other influences. As the diagnosis is defective the treatment not only does no good, but rather harm, if depletive, as it often is when "biliousness" or "apoplexy" are deemed causative of the vertigo. Finally, something draws attention to the ear as a possible factor in the production of the vertigo. Examination now

reveals the fact that the patient is a victim of chronic ear-vertigo, most commonly of that form found in the late stages of chronic sclerotic otitis media. Deafness and tinnitus are found to have been present for a long time, to which within a few months or even a year there has been added the most distressing symptom of all, viz., a tendency to frequent attacks of ear-vertigo. These may be so severe and so frequent as to keep the patient, especially if a woman, in bed for weeks at a time. If the patient be a man he is rendered unfit for leaving the house alone and attending to his daily avocation. He becomes low-spirited, his general health fails, and his will-power becomes impaired. If the patient persists in leaving the house and trying to work he is liable to be attacked at any time by severe vertigo, nausea, and vomiting, his face becoming very pale and bathed with clammy sweat. At this point he will reel and fall if not supported, but there will be no loss of consciousness. He becomes helpless and must be carried home. I recall a case of this nature in which the patient, a man of 40, was attacked while "on 'change" and was brought in semicollapse in a carriage to my office for relief.

Membrana Tympani.—If the membrana tympani of a patient affected with chronic catarrhal ear-vertigo be examined it will be found to present the usual appearance of the drum head in chronic catarrhal deafness, viz., opacity, thickening, and retraction. The retraction of the membrana may be so great as to draw the malleus upward and backward, towards the aditus. In most of such cases the incudo-stapedial joint can be seen through the upper, posterior quadrant of the drum membrane. The examiner then sees in the retraction of the membrane and ossicles the mechanical cause of the ear-vertigo. The retracted chain of bonelets, by pressing the stapes inward into the oval window and holding it there in a condition of undue retraction upon the vestibule and its fluid, compromises the latter space and compresses the labyrinth fluid upon the ampullar nerves in the semicircular canals and ear-vertigo is evoked.

Ear-vertigo is not constant, however, because varying conditions of relieved tension in the middle ear and the chain of ossicles, from the outer side of the stapes, and also similar variations in the labyrinth-lymph on the inner surface of the stapes footplate in the oval window, suspend temporarily the compression of the ampullar nerves and the patient is temporarily free from vertigo.

The stapes, however, being permanently in a state of undue impaction in the oval window, it requires but little additional inward pressure of the stapes from the tympanic side, or increased flow of lymph into the labyrinth to exert undue compression of the endolymph in the already compromised labyrinth space and irritative pressure upon the ampullar nerves, followed by an attack of ear-vertigo. Varying conditions in the health and circulation of the lymph or blood of the patient are sufficient to evoke these attacks in one in whom the drum cavity is already diseased and the labyrinth space compromised, i. e., contracted by the chronic impaction of the foot plate of the stapes in the oval window. In a normal state, undue inward pressure of the stapes into the oval window is compensated by a yielding of the round window membrane towards the drum cavity. In a normal auditory apparatus any undue increase in the flow of lymph towards the labyrinth, including of course the vestibule, is compensated by the recession of the stapes outward towards

the tympanic cavity and also by a similar recession on the part of the membrane of the round window. But if the stapes in the oval window and the membrane of the round window are rendered abnormally rigid, as they often are by chronic catarrhal otitis media, compensatory recession at these two points to intralabyrinth pressure is impeded, the intralabyrinth space is thus easily engorged by an inflow of lymph or blood, its fluid is compressed upon the ampullae, and ear-vertigo is the result. It can be thus seen that ear-vertigo is produced in a purely mechanical way, depending largely upon retraction of the tensor tympani and the ossicles in chronic catarrhal otitis media.

Ear-Vertigo in Chronic Purulent Otitis Media.—Ear-vertigo sometimes occurs in the subjects of chronic purulent otitis media. In these cases, too, the retraction and impaction of the stapes, by the superposed and enlarged malleus and incus, usually play the chief part in producing vertigo, for the malleus and incus in such instances are often covered with swollen and granulating mucous membrane, and bound firmly by synechiae to each other and the inner tympanic wall, and thus are made to press very forcibly upon the stapes. In these suppurative cases the bloodvessels of the mucous membrane of the drum-cavity are always deeply engorged, and as these vessels are intimately connected with the bloodvessels of the labyrinth, it is easy to see how the latter may become unduly engorged and excessive intralabyrinth pressure thus induced, resulting in ear-vertigo. Irritation and engorgement of the labyrinth, with resultant vertigo and nystagmus in purulent otitis may also be due to direct transmission of inflammation through carious openings from the drum-cavity into the horizontal semicircular canal, or at some other point in the outer wall of the labyrinth. Though the mode of production of the ear-vertigo in such cases is somewhat different from that in chronic catarrhal otitis, the mechanism is the same, viz., a mechanical pressure compromising the labyrinth space and compressing the ampullar nerves in the semicircular canals.

Treatment.—The cause of chronic ear-vertigo being a mechanical one, consisting chiefly in impaction of the stapes in the oval window, removal of this retractive force and liberation of the stapes will cure the disease. Consequently many years ago I devised an operation consisting in surgical removal of the incus, in cases of ear-vertigo originating from chronic catarrhal otitis. The removal of the incus breaks the retractive force of the tensor tympani and malleus exerted through the incus upon the stapes, and the latter bonelet is liberated.

In chronic purulent cases it is necessary to excise the remnants of the diseased membrana, and the malleus and the incus, with their synechial bands, in order to liberate the stapes.

This operation in such cases, supplemented by local treatment of the purulent drum-cavity, is followed by cessation of the vertiginous attacks, and cure of the chronic purulency. Thus excision of the diseased ossicles leads to curing the chronic purulency and acts as a prophylaxis of antrum and mastoid disease.

Operation.—The patient is etherized (local anesthesia by cocaine being both inefficient and toxic according to my experience) and the external auditory canal and the membrana sterilized by a solution of mercuric bichlorid (1 to 5000) or one of formalin (1 to 1000). Then the auditory canal and membrana tympani are illuminated by means of an electric light held on the

forehead and run by a small portable storage battery, made for the purpose of clinical illumination.

Where the membrana is intact, as it is in a case of chronic ear-vertigo due to chronic catarrhal otitis media, the initial incision is made with a delicate knife, beginning close behind the short process of the malleus and following closely the periphery backwards and downwards until reaching a point below the line drawn horizontally through the umbo of the membrana. This cut is followed by little or no bleeding as a rule. The flap thus made should be pushed inward towards the promontory by means of a probe armed with a small dossil of sterilized cotton. If there is no bleeding the incus-stapes joint is seen as soon as the flap of the membrana is pushed aside. If there is bleeding it must be mopped away with sterilized mops on a cotton holder.

The incus being now in plain sight, it should be gently disarticulated from the stapes by drawing the former outwards and downwards by means of an incus-hook knife passed behind its long limb. When this is done the long limb of the incus should be grasped by special forceps and drawn very cautiously downward and outward into the auditory canal and then removed entirely from the ear. When this is accomplished the operation is finished. The slight bleeding that sometimes occurs in the chronic catarrhal cases requires no attention. The meatus should be stopped with sterilized cotton and the ear let alone for 24 or even 48 hours, unless the cotton in the meatus gets moist with blood or serum. If this occur the cotton should be removed and dry cotton inserted. There is to be no after-treatment in such cases, as all is accomplished when the incus is removed. As a rule there is no reaction in these cases, and the wound in the membrana heals by first intention. Sometimes a slight reaction has occurred, shown by a little pain and some mucopurulent discharge. But this is healed in a few days by simply mopping the ear with sterilized cotton and a solution of formalin (1 to 1000) and such reaction has never had any bad effect upon the result of the removal of the incus in checking the vertiginous attacks in any of my cases. A serious reaction I have never encountered after the operation, neither in the chronic catarrhal nor in the chronic purulent class.

The mode of operation in the purulent cases is different from that in the chronic catarrhal cases with intact drum-membrane. In the former the membrana is already perforated and the ossicles, if still present, plainly visible in most instances. The incus should be detached and removed first, and then the remnant of the diseased membrana and malleus should be completely excised. Hemorrhage in such cases is always relatively great and delays the operation, as the field of operation requires constant and complete mopping before the surgeon can proceed. After the operation the ear requires syringing with a bichlorid solution (1 to 5000) and the ear should not be stopped with cotton, but allowed to discharge. The subsequent treatment must be that indicated in a case of chronic purulent otitis media. I have performed this operation in its two forms named above in 27 cases of chronic ear-vertigo, mostly in *chronic catarrhal otitides*, and in no instance has it failed to give relief, and I know of no other kind of equally successful treatment of chronic aural vertigo (Ménière's disease). In two instances entire and prompt relief from ear-vertigo of over a year's duration, *following mumps*, has been afforded by the surgical removal of the incus as described above.

A NEW HEMOGLOBINOMETER FOR THE EXAMINATION OF UNDILUTED BLOOD.

By ARTHUR DARE, M.D.,

of Philadelphia.

Clinical Assistant, Medical Department, Jefferson College Hospital.

THE instrument described in this paper is the outcome of a considerable amount of observation directed to the estimation of hemoglobin by the colorimetric method with undiluted blood. The application of the instrument depends upon the principle that the color of a thin film of undiluted blood, illuminated by candlelight, can be compared with a graduated color-comparison. The results obtained from it are uniform and accurate and, chiefly, more definite than those obtained from the dilution methods. Furthermore the operation of the instrument is sufficiently simple to place hemoglobin estimation within the possibilities of clinical routine.

The material used for observation was selected from the Out-patient Medical Department of Jefferson College Hospital, and from private cases. A large number of the anemias were examined, including chlorosis, pernicious anemia, splenomedullary and lymphatic leukemia, Hodgkin's disease, fatal hemorrhage, and numerous cases in which the hemoglobin was deficient as a secondary symptom. The patients were seen at regular intervals, the blood examined, and the rise or fall in the hemoglobin percentage carefully noted. In all cases comparisons were made with the von Fleischl hemometer and with the Oliver hemoglobinometer. In using the von Fleischl hemometer it was placed in a special camera box, by which all extraneous light was excluded and the conditions surrounding the comparison of color made uniform. With the Oliver instrument the candlelight scale was used exclusively, so that the quantity of light thrown upon the blood-cell and the standard gradations was kept equal, and a greater accuracy of observation insured than was possible with the scale standardized by daylight.

For the purpose of colorimetric observation in the instrument here described, the blood is drawn by capillary attraction into a chamber of measured thickness, presenting sufficient surface for a color field, and illuminated by candlelight. Between the blood-film and the source of illumination a white glass slide is interposed to diffuse the direct rays of light. Against this white background the shades of color are observed to the greatest advantage, and are compared with a graduated color prism of tinted glass which represents the percentage of hemoglobin in the blood examined.

The determination of the standard for hemoglobin percentage in normal blood is a matter of observation. Von Fleischl examined a number of healthy male adults and represented the normal hemoglobin percentage in Austria by the 100 mark on his instrument. In the Oliver hemoglobinometer the 100 mark, or normal point, is somewhat lower, and probably represents more nearly the normal in this country. The gradations on the instrument at present under discussion were standardized by comparison of blood-strata of thicknesses varying with mathematical uniformity. To fix the 100 mark—the color-shade of normal blood—hemoglobin prepared especially for the purpose by Messrs. Armour & Co., of Chicago, was reduced and the impurity determined. The standard for normal blood was fixed at 13.77 grams of hemoglobin (adjustment being made for impurity) mixed with 100 cc. of saline solution. From this point

the percentage above and below was determined by means of pipets containing blood-strata of thicknesses representing hemoglobin percentages from 10 to 120. Freshly drawn blood reading 100% by the comparison scale was used for subsequent observations in preference to diluted hemoglobin. Comparisons were then made with impoverished blood and found to agree accurately with the standard set by the various strata

of normal blood. To standardize with diluted blood was impossible, because of the discrepancy due to the color-curve, though gravimetric and volumetric dilution methods were tried (the former most accurate). The readings in all cases were verified by comparative tests with Oliver's instrument and found to be in accord throughout the scale. The Oliver instrument, according to the claims put forth, makes perfect adjustment for the color-curve. With this new hemoglobinometer dilution is not practised and the dilution color-curve is accordingly excluded. The color-curve peculiar to every specimen of freshly drawn blood, which is an intravascular dilution presenting various degrees of hemoglobin concentration, is to all purposes eliminated from the experiment, by keeping the concentration of coloring matter in the comparison prism equal to it, *e.g.*, in comparing a film of blood rich in hemoglobin a thicker stratum of tinted glass is required to give an equal color-shade, and vice versa. The specific color, or absorption-curve, is by this means entirely adjusted.

It may be noted that observations less accurate can be made with the pipet of this instrument alone. The blood-drop may be placed between the two parallel discs of glass, adjusted to desired thickness by a graduated micrometer screw, and the hemoglobin percentage estimated by comparing with a color-comparison of known percentage.¹

The pipet for collecting the blood consists of an oblong piece of glass placed between the blood-film and the candlelight. It is composed of white or opaque glass of standard color, which diffuses the direct rays and serves as a neutral background against which shades of color are best appreciated. At one end is ground a square depressed surface exactly parallel to the plane

surface of the glass, and measured with a micrometer to give an exact depth. This depression forms a capillary chamber when the transparent glass completing the pipet is adjusted over the white. The two glasses are of equal size, the surfaces ground perfectly plane, and the colorless glass is polished to preserve its transparency. When clamped tightly together with a pipet clamp the chamber contains a blood-film of definite thickness and fills automatically by capillary attraction when any of its three edges is gently touched to a blood-drop.

The pipet clamp is formed of metal with two projecting parallel bars, between which the glasses of the pipet are placed and firmly held by a milled screw, threaded into the upper arm and pointed with bone to lessen the liability of breaking the glass. Since the pressure is directly in the center of the articulating surface of the white and the transparent slides, it is impossible to tilt the edges by uneven pressure. Grooves on the lower arm into which corresponding guides on the stage of the instrument slide, retain the blood pipet in proper position for examination.

When the film of blood is thus collected by the automatic pipet and spread out sufficient for colorimetric observation, a comparison is made with the tinted glass semicircle of the comparison prism. This semicircle is the color of undiluted blood, and so ground that from apex to base it shows an increasing shade. It is mounted upon a disc of white glass to diffuse the direct rays of light and furnish a neutral background against which the shades of color are best appreciated. The other semicircle mounted on the disc is a thick plate of white glass, upon the edge of which the hemoglobin percentage is etched and filled with black enamel, giving a legible index reading. The thick edge serves also as a friction-surface for the rubber-covered roller that revolves the comparison-prism. The shade of color shown in the comparison-field is regulated by a milled wheel carrying a small rubber-covered cylinder which rests firmly upon the circular edge of the prism. Free rotary motion of the color-prism is allowed by the pivots upon which it revolves. The shaft serves as pivot for the prism

¹It is interesting to note that this principle of strata-thickness we have applied to the estimation of hemoglobin percentage without drawing the blood from the body. The ear-lobe is washed, dried, and the circulation actively stimulated by massaging. Active congestion is allowed to subside by waiting five minutes (this stimulation of the circulation previous to the application of the instrument to the ear-lobe prevents the congestion due to its pressure and insures the filling of the capillaries). A color prism similar to that used in this instrument, but reversed—white glass towards the observer—is compared with the color shade observed in the circulating blood of the auricular tissue viewed through a circular aperture which is closed by a transparent glass window and illuminated by a five volt electric lamp. The lamp is enclosed in a reflecting tube made to press a glass disc mounted on its end against the opposite surface of the ear-lobe by an adjusting screw. The tissue is held between the two parallel glass discs exsanguinated without additional pressure, a mechanism is then released that gives a definite strata-thickness into which the blood pours. Comparison is made and the hemoglobin percentage read off. When this method was used on the negro, compensation was made for darker shade of color by having the opposite side of the comparison disc covered with a close woven light paper giving the exact shade produced by pigment spots visible in the illuminated skin. By considerable practice the hemoglobin percentage could be calculated within 10 or 15, but as there is no definite point of departure the method is very uncertain and merely mentioned in passing as a curiosity.

passing through the center and is covered with soft rubber. Discs of rubber are interposed between the

glass and the metal washers binding the prism to the hub. This cushion produces a resiliency that admits of considerable violence without injury to the comparison-disc.

The index of hemoglobin percentage is read off at a point opposite the color-apertures. The rectangular opening in the edge of the comparison-case is of sufficient size to allow the numerals above and below the percentage indicated to be seen at a glance—the sharply

FIG. 3.—Color prism. *E*, Prism of colored glass, *F*, Semicircle of white glass, the edge carrying the index of hemoglobin percentage etched and filled in with black; this edge also serves as a friction surface for the rubber-covered roller by which the prism is rotated. *G*, Hole in which hub is fixed with rubber washers which lessen liability of breaking. Pivots in center of metallic case hold the prism firmly in place, allowing free rotary but no lateral motion. *H*, Index of hemoglobin percentage etched in black, showing very distinctly. *I*, Disc of white glass which serves the same purpose as in the blood pipet, breaks the glare of direct light and furnishes a white background to view the shades of color.

beveled edge of the opening resting directly over the reading indicated. The divisions and subdivisions in the comparison-disc allow the most accurate reading of the percentage below and above the normal.

The framework of the instrument, assembling the essential parts, is simply a thin, circular, black enameled aluminum box containing the comparison disc, which it protects from dust and injury. From this a small stage projects, upon which the blood pipet slides, and is retained by guides. Pivoted to the posterior surface is a circular metal disc, the diameter of which is exactly that of the case upon which it lies when not in use. When pushed outward it forms a screen that shades the eyes of the observer from direct candlelight. Besides, by raising and lowering slightly, it may be used also to close the illuminated color apertures and rest the eye of the observer by allowing the pupil to dilate in the darkness.

The illuminated blood-film and the color-comparison disc are viewed through two circular apertures placed on a horizontal plane; one communicating with the stage, the other with the comparison case, the two compartments separated by a septum of metal. The orifices, which are 5 mm. in diameter, cover a surface of the comparison prism equal to 3%, but are magnified by achromatic lenses fitted in the camera-tube to give a larger color-field for comparison, and to facilitate rapid and accurate observations. The apertures are placed 13 mm. apart, a distance best suited to colorimetric comparison. A telescoping camera-tube, attached to the instrument by means of a threaded socket, excludes all extraneous light. In focusing, should the blood-film present a mottled or stippled appearance, as is occasionally observed when the pipet is imperfectly filled, the focus should be changed to blur the field and render it homogeneous—the color is not altered in the slightest by the focus, as long experience has shown. In obtaining uniform illumination the candle has been selected as the most portable and convenient. With it the intensity of light can be regulated to impinge equally on the blood and the color-prism. The candleholder consists of two lateral springs attached to a shaft which is inserted into a guide on the comparison-case and retained firmly by an automatic catch. It holds

the candle rigidly in a vertical position midway between the blood and comparison-apertures at a distance from the field most favorable for accurate comparison.

Before drawing the blood the instrument should be prepared for immediate observation by swinging the screen outward and attaching the camera-tube and candleholder. The top of the candle and the springs should be on the same plane; if there are any curves in the candlewick they should be turned toward the instrument and in a line with the junction of the springs, so that the intensity of the candlelight will be equally divided between the blood and color-comparison sides. A means of lighting should be at hand, as the comparison should be made before the blood in the pipet shrinks from the edges and whitens the margin of the field—a phenomenon which occurs in from 10 to 20 minutes. The shade remains constantly the same until the retraction of the edges shows in the field; then the readings are no longer accurate. Before this occurs, however, a dozen or more readings can be made, even in blood undergoing contraction within the minimum time. If the pipet is washed in ether or alcohol and carefully polished this change does not occur for an indefinite period, for retraction is accelerated by an oily condition of the pipet glasses, or by incomplete filling of the capillary chamber.

No other preparation is necessary. When the instrument is used in daylight, the observation is best conducted in a darkened corner or a closet, if one is convenient; if not, the instrument should be held pointing toward a dark surface—a black coat, for instance—which does not reflect rays of light. The observer should stand with back turned toward the source of direct or reflected light. No provision is made for the occlusion of the violet rays of daylight, which, when transmitted through the field, change the tint of both the blood and the comparison-colors. They must therefore be excluded. The illumination by lamps or gas-lights does not interfere, as yellow light shuts out the violet rays.

Any appliance to make the observation entirely in camera would add to the bulk of the instrument—a

FIG. 4.—Instrument ready for use, illustration one-half natural size. *P*, Milled wheel by which the color prism is rotated by friction exerted upon its edge. *S*, Metal case enclosing color prism, showing stage upon which the blood pipet slides. *T*, Movable wing pivoted to case. When drawn outward screens the eyes of observer from the light. When not in use lies superimposed upon the circular prism case, occupying no extra space. *U*, Telescoping camera tube in position for examination. *V*, Opening in prism case, admitting light for illumination of color prism. The white glass disc of prism is seen inside. *W*, White glass of blood pipette. *X*, Pipet clamp held in position on the stage by grooves and guides. *Y*, Detachable candleholder. *Z*, Rectangular opening in edge of case for reading hemoglobin percentage indicated by beveled blade.

result which has been avoided in all ways possible. We have used a small inclosed 5-volt electric lamp, but

the weight and size of a satisfactory battery are a serious drawback to this; in fact, the expense and trouble of recharging it renders it absolutely impracticable.

Filling the blood pipet is the only act in the examination involving the slightest technical skill. Even this is accomplished without the slightest difficulty if the pipet is dry and clean. The lobe of the ear or finger-pad is prepared and punctured in the usual manner. The pipet, held with the transparent glass upward, is touched to the blood-drop as it emerges from the wound. If the blood is thin and watery and runs close to the surface, the pipet should be held against the skin below the flowing blood, which is then caught and drawn into the chamber. When this is completely filled, the excess upon the edge can be wiped off against the patient's finger or ear-lobe by a slight motion, but care must be taken that no blood is sucked from the capillary chamber by the movement. Blood-stains upon the flat surface of the pipet should be removed, but they may remain upon the edges if not in sufficient quantity to soil the instrument, as the edges do not come into the field of observation. When the observation has been completed the glasses should be removed from the clamp, washed, dried, and returned. Cleansing is more readily accomplished while the blood is fresh.

In making comparison of color the instrument should be held in much the same manner as field-glasses—that is, up before the eyes, so that they may be screened by it from the candlelight. The proper distance will be determined by the focus best suited to the vision of the observer. One eye, close to the lenses, should be used, as uncorrected refractive errors existing in either eye may influence the accuracy of color-vision. The most accurate comparisons can be made by observation lasting from 10 to 12 seconds; the eye should then be rested by dropping the screen, and the comparison repeated.

The instrument has several decided advantages over the others employed for a similar purpose.

1. The technical requirements and the possible errors of dilution are entirely eliminated by it, for only a small drop of fluid is needed, and this consists of pure blood, undiluted with artificial serums. Leukocytosis—a frequent source of error in hemoglobin estimation, because of the turbidity it imparts to mixtures of blood and water—becomes imperceptible when viewed by transmitted light against an opaque background. The red color of the hemoglobin alone becomes visible, while the opacity due to the increase in the number of leukocytes is negligible.

2. Accurate investigation is facilitated by the fact that the shades of color for comparison are very decided, even in blood markedly deficient in hemoglobin. For besides the colorimetric principle, there is an element of density due to the concentration of coloring-matter present in the blood-film, which magnifies the shade of color, gives a wider range between decimal points, insures more uniform comparison, and greatly reduces the "personal equation."

3. The examination—consisting merely of collecting the blood and estimating the hemoglobin percentage by comparison with a graduated color-scale—requires very little time. The plain surfaces of the blood pipet can be cleansed and the whole procedure ended in the time ordinarily required to take the temperature. This rapidity places hemoglobin estimation among the practical clinical methods.

4. The pipets all contain a blood stratum of standard thickness and can therefore be used with any instrument—a distinct advantage over the calibrated pipets which have a capacity only adapted to one particular apparatus.

In conclusion a few comparisons may be drawn between the instruments of von Fleischl, Oliver, and that which is the subject of this paper.

In the von Fleischl instrument the capillary blood pipet is a fragile glass pipe requiring the most careful handling. It is cleansed and dried by blowing a mixture of alcohol and ether through its caliber. Blood-clots forming from too long retention or from conditions hastening its coagulation narrow the capillary tube and introduce a source of error. The dilution not only requires some technic and considerable time, but also a ready supply of distilled or perfectly clear water. Leukocytosis, furthermore, imparts to the mixture of blood and water a turbid appearance which does not correspond with the clear tone of the color compartment, and the opacity thus interposed to the reflected light viewed through a thick stratum of muddy mixture makes the comparison inaccurate unless clarified by caustic alkali. And, finally, the exceedingly delicate shades of color to be compared render exact comparison difficult in blood deficient in hemoglobin. A camera-box or a dark room is absolutely necessary for its application.

The Oliver instrument is in several respects an improvement over the von Fleischl. The blood pipet is much stouter, and can be readily and perfectly cleansed by passing through its caliber a needle threaded with woolen yarn. By using a smaller quantity of diluting serum with an equal quantity of blood a more concentrated mixture is obtained, the color of which is still more intensified when viewed by doubly reflected light. Nor is leukocytosis so pronounced in the Oliver instrument as in the von Fleischl, where the light traverses the turbid mixture interposed between it and the eye. A bubble of air invariably forms when the blue tinted cover-glass is adjusted over the blood-cell (unless overfilled) but by rotating the cell or moving the cover-glass, the shadow cast by the bubble may be made to fall at a point out of the field of observation.

The difficulty with the Oliver instrument, on the other hand, is that frequently no manipulation will clear the field of the bubble or its shadow, which thus becomes a source of inaccuracy. Furthermore, for accurate work the examination should be made by candlelight, which requires a darkened room or camera-box. The variability of daylight is too great for satisfactory results. As the standard gradations in the Oliver instrument represent divisions of 10%, color comparison is greatly facilitated. But between these points the results are not so precise. The greatest objection to the instrument is the trouble of cleansing and assembling the sundry small parts.

The advantages of the instrument which is the subject of this paper, briefly recapitulated, are these: An immense amount of labor is saved by dispensing with dilution and its possible errors; leukocytosis cannot influence the results; adjustment is made for the color curve; the color shades for comparison are made more decided; the pipet is absolutely cleaned; and, most important of all, the readings are uniform and accurate and depend upon principles which allow the best analysis of color shades in the shortest time. Results within 1 or 2% are obtained with a certainty hardly obtain-

able with other instruments. Clinical patients who took a lively interest in the examination of their own blood, when asked to make comparisons, rarely exceeded a variation of 2% in successive trials. In the case of shop-girls who were accustomed to match colors the variation was still less.

In considering this instrument, its simplicity, its compact construction, lightness, and portability, as well as the accurate results obtainable with it, should be taken into account.

I wish to thank Messrs. Armour & Company for the specially prepared hemoglobin used in making the standards of comparison for this instrument.

ACUTE SEMINAL VESICULITIS.¹

By HENRY H. MORTON, M.D.,

of Brooklyn, N. Y.

Clinical Professor of Genito-Urinary Diseases in the Long Island College Hospital, Genito-Urinary Surgeon to Kings County and Long Island College Hospitals and the Polhemus Memorial Clinic.

ACUTE inflammations of the seminal vesicles are generally caused by gonorrhea, although a chronic inflammation may originate from other causes. A gonorrheal inflammation of the interior of the cavity of the vesicle is excited when the gonococci pass from the posterior urethra through the ejaculatory ducts, and are deposited within the vesicle. Its walls secrete pus and its cavity soon becomes filled up and distended with a purulent accumulation.

The *symptoms* are not very characteristic and are merely those of the posterior urethritis which of course is always present. Fever and a throbbing pain in the vesicles and tenderness in the suprapubic region are always observed.

Seminal discharges, which are red or chocolate-colored from the admixture with blood, often occur. The blood may be derived from the cavity of the vesicle itself or may be acquired by the semen from a congested posterior urethra, as it passes through it. If the posterior urethritis is cured the urine is clear at first, but later in the disease, the vesicles pour out their purulent contents into the posterior urethra and the pus flows back into the bladder, discoloring the urine when it is passed.

The *diagnosis* of seminal vesiculitis can only be made by rectal examination and the vesicles can be felt swollen, soft, fluctuating, and intensely tender. Epididymitis is a most frequent result of vesiculitis and is brought about by some of the gonococci-laden pus-cells being carried through the vas deferens and deposited in the epididymis. Peritonitis, which sometimes becomes general, may occur, from the close relation which the peritoneum bears to the vesicles.

The *treatment* of acute vesiculitis is chiefly expectant and consists in putting the patient to bed and giving a saline cathartic, which is always in order in every pelvic inflammation. Hot sitz baths and copious irrigations of the rectum with hot water are useful in allaying the inflammation. If the posterior urethritis is severe, sandal-wood oil relieves the tenesmus and renders the urine less irritating. Injections into the anterior urethra of course are contraindicated, but above all things any attempt at massage or stripping the vesicles should be absolutely interdicted. Under this plan of treatment most cases of acute vesiculitis will recover in from two to

four weeks' time, but when resolution does not occur, the disease passes into the chronic state.

CHRONIC SEMINAL VESICULITIS was but little understood until 1893, when Eugene Fuller published his first paper on the subject. Chronic vesiculitis may originate from an acute attack of vesiculitis which has not undergone resolution, but as a rule it develops insidiously, as the result of extension of a chronic inflammatory process which begins in the posterior urethra and extends through the ejaculatory duct. The ejaculatory duct is never compressed by the changes, but throughout the whole course of the disease it remains open and patulous and sterility does not occur.

Pathology.—In chronic vesiculitis the inflammation, instead of causing the cavity of the vesicle to become filled with pus, as in the acute form, attacks the *walls* of the vesicles and the perivesicular connective tissue. The inflammatory products which were thrown out into the connective tissue around the vesicles become organized into a hard, fibrous tissue, which binds the vesicles down to the bladder, and the entire mass composed of vesicles imbedded in fibrous tissue appears like a part of the prostate and may be easily mistaken for it on rectal examination. During exacerbations a good deal of pus may be secreted in the walls, which results in a filling up and distention of the cavity of the vesicle with pus.

Two varieties of chronic vesiculitis are recognized: (a) Simple and (b) gonorrheal. The symptoms and treatment of these forms are identical and they only differ in etiology.

SIMPLE VESICULITIS may originate as a result of sexual excesses, masturbation, etc., exciting a low grade of inflammation in the posterior urethra, which extends along the ejaculatory duct. The ejaculation of semen is interfered with, and the contents of the vesicles which are retained become thick and inspissated. The diseased process is still further complicated by germ-infection. Simple pyogenic organisms pass from the urethra along the ejaculatory duct or *Bacillus coli communis* works its way in from the rectum. In old men who are being broken in to catheter life, the traumatism often excites a subacute inflammation of the vesicles which frequently extends to the epididymis.

GONORRHEAL VESICULITIS may result from an acute attack which does not undergo complete resolution, but is more commonly occasioned by a chronic inflammation of the posterior urethra caused by gonococci, which extends slowly along the ejaculatory duct.

The gonococci enter the cavity of the vesicle, penetrate the epithelial lining and may remain dormant until excited to activity by various causes, such as a long walk or bicycle ride, or an excess of beer, or coitus. Under such slight provocations a relapse occurs with abundant pus-formation, and gonococci are found, on microscopic examination, in the secretions.

Diagnosis.—The clinical history of these cases is generally significant of involvement of the vesicles. The patient complains of a gonorrheal discharge which lasts, with intermissions, for years. Any slight indiscretion brings on an exacerbation, which is often mistaken for a fresh attack of gonorrhea. The discharge lasts for a few days and then subsides, until another indiscretion lights it up again.

The *symptoms* depend chiefly upon the accompanying posterior urethritis, and consist in frequent urination, and spasm or irritability of the cut-off muscle. On straining at stool a glairy, sticky discharge escapes from the meatus, which is the secretion expressed from the

¹ Read before the Kings County Medical Association, April 10, 1900.

prostatic crypts by the muscular efforts and is termed prostaticorrhea.

The mental symptoms are always very prominent and the individual suffers from depression of spirits and melancholy, irritability of temper and quarrelsomeness. Hypochondria is notably marked and patients are alarmed over ridiculous trifles. They complain of the penis being shrivelled, cold or numb, that the testicles are retracted or that one hangs lower than the other, and suppose that the testicles are beginning to atrophy and they are growing impotent. In their alarm they consult some of the advertising quacks who prey upon their fears and deluded ignorance.

Another important group of symptoms is connected with the sexual function. In the early stages there is an increase in the sexual desire, with frequent nocturnal emissions and premature ejaculation on coitus. The seminal discharges are often mixed with blood which may be acquired from the posterior urethra or the cavity of the vesicles. As the case progresses, erections cease, the sexual desire is lost and at last a condition of true impotence is established.

The diagnosis can only be made by rectal examination, and in order to determine the condition of the vesicles a very considerable amount of practice is necessary in order to attain the necessary "tactus eruditus." As the vesicles and prostate are continuous it is difficult for the beginner to differentiate them and until one is experienced a diagnosis of enlargement of the prostate is generally made, when the vesicles alone are enlarged and the prostate is normal in size.

Technic of Examination.—The patient, with his bladder moderately distended with urine, assumes the "leap-frog" attitude, bending over a chair and grasping the sides with the hands. The surgeon makes counter-pressure with one fist doubled up, pressing against the bladder, and the index finger of the other hand is inserted into the rectum. In order to get well up beyond the upper margin of the vesicle, it is necessary for the surgeon to support his right foot on a chair and by means of his knee, make strong pressure against the elbow of his examining hand, in order to drive it well in.

If the vesicles are normal they feel soft and the amount of distention depends on circumstances. If endovesiculitis is present they feel large, distended, tense and very painful. If perivesiculitis exists, they are hard, indurated and brawny, feeling like a piece of pork, on account of the infiltration through the connective tissue, which surrounds the vesicles and forms adhesions which binds them down upon the bladder.

After examining the condition of the vesicles their contents should be stripped or expressed by the examining finger, beginning at the upper margin and squeezing or stroking in a downward direction, so as to press out the contents through the ejaculatory duct. The quantity of expressed material which runs out at the meatus varies from a few drops to half a dram or more. On examination the material is found to be thick and jellied or purulent and the spermatozoa are dead. As the case improves the spermatozoa regain life and motion.

The treatment consists in stripping or expressing the contents of the vesicles once in from 5 to 7 days. The effects of stripping are to empty the vesicles of their inspissated contents, without forcing the muscular fibers to contract and eject the semen and through the rest thus afforded them, the muscles recover their tone. The

inflammatory thickening around the vesicle is absorbed as a result of the massage.

Contraindications to stripping are the existence of an acute attack of vesiculitis, blood in the expressed material, or excessive tenderness. With these conditions present there is always danger of setting up an epididymitis.

The posterior urethra should not be overlooked but should receive appropriate treatment, with irrigations or instillations or by the endoscope. It is desirable, however, not to use local treatment to the posterior urethra and strip the vesicles at the same sitting, but to allow a couple of days to intervene. The duration of treatment is protracted, requiring from two to twelve months to effect a cure; but since Fuller's work upon the subject, it is possible to cure cases which were beyond the reach of treatment before.

TUBERCULOUS VESICULITIS.—In this condition the vessels are involved by an infiltration with tuberculous nodules. The symptoms are not marked and the disease exists unsuspected. Tuberculous vesiculitis has its origin primarily in epididymis and extends upwards along the cord to vesicle, or, primarily in the vesicle and involves the epididymis and testicle subsequently by extension downwards through the cord.

The diagnosis is made by feeling the vesicles through the rectum, and the hard, irregular nodules can generally be felt in addition to the perivesicular induration. Tuberculous deposits are usually found in other organs, particularly the lungs, bladder and epididymis, and it is a good rule to examine the vesicles in every case of suspected tuberculosis of the epididymis or testicles.

The treatment consists in hygienic measures alone, of which the most important is an outdoor life in a suitable climate. Codliver oil and creasote are the drugs most in vogue.

The local treatment by stripping is contraindicated and will only make matters worse.

THE INJURED TRAMP: WHO IS RESPONSIBLE FOR HIM?¹

By F. JULIAN CARROLL, M.D.,

Local Surgeon at Summerville, S. C.

The tramp is a prominent and ubiquitous member of that large army generically classed as "the poor," and "the poor ye have always with you."

Nowhere, I suspect, is the omnipresence of this congenitally weary son of the soil more felt than in and about railroad towns. He is too tired to walk along rural roadways, but manifests an alarming amount of energy in boarding and getting off railroad trains.

Indeed, the tramp is as much a part and parcel of a well-conducted railway as is the engine and cars, the track, the trainman, the superintendent, or the receiver, and, along with the rest of railway employes and appurtenances, he is occasionally subject to injury.

Once injured the tramp falls to our lot and becomes of interest to us as railroad surgeons. If this accident has happened near a large city where hospital facilities are at hand, all is plain sailing, and we know what to do with our dirt-begrimed son of ease. Should this accident, on the other hand, occur elsewhere, and should this gentleman of much sand and little water who has

¹ Read before the Association of Southern Railway Surgeons, at the annual meeting in Charleston, S. C., May 11, 1900.

been inconsiderate enough to get himself injured, further aggravate his offense by electing the locality of his accident in or near some small town, the local surgeon at the aforesaid small town is assailed by a peck of difficulties, the most prominent of which suggests a part of the title of this paper,—“Who is responsible for him?” What are we to do with him? Truly we have an elephant on our hands!

If we have been provident enough to have saved our contract signed in triplicate between ourselves and the Southern Railway System, we hasten to consult that. In Form 1402, in effect January 1, 1897, we find the following clear and specific (*sic*) directions laid down for our guidance and direction:

“In case of tramps the patient should be turned over to the authorities or to charitable institutions.” We are also informed that the Company is not responsible for our fees after the first visit.

Now these directions are all right so far as they go, but, like Montijo's cannon at the battle of Manila Bay, they don't go far enough. Perhaps some of you have been out with a gun looking for those authorities which the kindly author of Form 1402 speaks so affably of. If you haven't you don't appreciate the keen irony of this sentence as we who have, do. Besides, “the authorities” is rather vague. What authorities? Railroad? State? County or town? If this is our first case we might spend a couple of profitable hours sending telegrams to the various authorities trying to find out which one of these is the responsible party. Of course, the profit above alluded to comes in for the Western Union Telegraph Company. Meanwhile, how about our patient? Are we to pay our first visit, chalk up two dollars against the Southern Railway, and leave this human being, tramp though he is, to suffer, perhaps to die, while he is waiting for “the authorities” to come along?

And what about those “charitable institutions” which our instructions so generously place at our disposal?

Now the only reasonable objection we can urge against these “charitable institutions” is that they do not exist. They are phantoms created by the kindly imaginations of philanthropists, and if brought into the world they are still-born.

“Charity covereth a multitude of sins.” Charitable institutions many multitudes. In truth we might paraphrase an old and eloquent passage to read “Charity! Charity! how many crimes are committed in thy name!” But we are wandering afield, for in small towns we haven't either “charitable institutions” or institutions bearing the name of charity. We have no hospitals of any kind.

And all this time what of the injured tramp? “Haden't thought of him” I can almost hear some one say. Unfortunately that is precisely the attitude of those mythical authorities and alleged charitable institutions, but we as physicians can't get this injured human being off our minds so easily; for, accepting David Harum's dictum that “thar's as much human natur in one man's in another—ef not more,” we are bound to help this human being.

As humanitarians we are often willing to take our two-dollar fee and attend this tramp without further remuneration, but the question that “will not down” confronts us: “Where are we to put him? Who is to provide nourishment and nursing?”

There is a widespread belief among a large class of people that railroad companies are invariably responsible for all injuries received on their lines, regardless of whether inflicted on employe, passenger or a tramp stealing a ride, and never mind how criminally careless the injured party may have been. Besides which, many persons otherwise charitable fear and abhor a tramp and will have none of him. Reasoning thus, private individuals, who under other circumstances might serve in lieu of the absent “authorities” or “charitable institutions,” wash their hands of the whole business and “pass by on the other side.”

We have, I think, most of us, had this condition of affairs forced home to us on more than one occasion. I recall at least three instances in my own experience, one of which I record as typical and illustrative of the others.

On September 15, 1899, John Sanders, a colored youth of about 18, was injured fatally while attempting to board a train on the Southern. This accident occurred at about 10 A.M., in the depot at Summerville, and I was promptly summoned, reaching the boy a few moments later.

On arrival I found my prospective patient lying in the colored waiting-room, surrounded by the usual collection of idlers. On a hasty examination I discovered that his right leg was crushed and pulpified from the foot to above the knee-joint; his right hand was also badly lacerated and several of the fingers were mashed off. He exhibited all the well-known symptoms of shock and seemed unusually weak, besides which he was suffering intensely, so I promptly administered morphin with atropin hypodermically and put a temporary dressing on his leg. The patient having lost considerable blood I also applied an Esmarch's tourniquet, which apparently controlled the hemorrhage effectively.

I now telegraphed the only authority I knew anything about, *i. e.*, the railroad superintendent, for further instructions. The results were not as satisfactory as I might have desired. I was told to send my patient home. As will subsequently appear I obeyed instructions in so far as in my power lay, and if that boy isn't home yet it isn't my fault. If we consider home in the nature of a mere earthly abode, however, I failed most dismally.

It appears that this boy had an uncle living in Summerville, so I summoned this gentleman post haste, and requested that he take my patient to his home. He reluctantly acquiesced, and the boy was put on a wagon to be hauled to his uncle's domicile. In the meanwhile, however, either through the potency of his wife's loving arguments or by the advice of friends, this affectionate uncle changed his mind—and made a bad swap—the result of the change being that he met us when we were about half way to the house and positively declined to have anything to do with the case.

All my eloquence, including threats, arguments, and persuasion, failed signally to make this old codger see matters in their proper light, and we must perforce turn about and take the boy back to his downy couch of planks at the depot.

Leaving a medical student in charge I went to attend to some necessary business, directing that my patient should be liberally stimulated during my absence.

On my return at 2 P.M., I found my patient considerably weaker and apparently losing ground rapidly. I examined the leg and found that considerable oozing

had taken place through the dressings in spite of my Esmarch.

Seeing matters were growing graver with each moment of wasted time, I again communicated with the superintendent's office and obtained permission to do everything necessary for my patient. I now made desperate efforts to get some of the bystanders to take this boy in at their homes for a moderate consideration. Finally one of them, contrary to the advice of the rest, was moved to accept my proposition. The half-dead boy was accordingly again placed on a wagon, after having received nitroglycerin hypodermically, and taken to this negro's cabin.

We now made ready to operate in the meantime; as soon as a bed could be prepared, my patient was placed on it and surrounded by hot-water bottles, the foot of the bed raised and the patient warmly covered. In spite of the above, together with bandaging all the limbs, and giving hypodermics of ether, whisky, nitroglycerin, strychnin, etc., my patient failed to react, and died at 4 p.m., just in time to escape the transfusion which I was preparing to give.

Now I am not prepared to say that this negro could have been saved had I been able to afford prompt attention, for he showed a remarkable degree of shock from the first; still I believe that if we had been able to take this boy where he could have been promptly transfused and otherwise stimulated, and where hemorrhage could have been promptly checked, his chances would have been considerably enhanced. It is our duty to give our patients every possible chance of recovery, and under conditions similar to the above it is impossible to do so.

Unfortunately we are unable to suggest a remedy because we do not know who to look to as having authority. In other words, who is responsible? Which brings us back to our starting-point.

We have consulted Form 1402 without obtaining any solid information, so we look for knowledge in the South Carolina statutes, with results which are absolutely discouraging. A diligent search on the part of myself and a legal friend failed absolutely to unearth anything in the slightest degree germane to this subject. And I am as much in the dark as ever. As far as I can understand the matter, a railway company is situated very much in the same manner as a houseowner in a small town without a hospital would be if an unfortunate were taken sick and lay down on this houseowner's door steps. The houseowner isn't responsible for the man getting sick, nor is he responsible for his being on the door steps; still he doesn't want him to stay there, and he is willing to make some sacrifices, pecuniary or otherwise, to get rid of him. This isn't charity, but it often amounts to the same thing, and the motives which inspire the property owner are about as worthy as those of the average charitable individual. Now the Southern makes its donation to charity when it pays us \$2.00 for our first visit. After that it shakes the dust of the tramp from its feet—if a railroad can be said to possess such appendages. It has paid its donation and is glad to be rid of the tramp so cheaply.

I do not for a moment intend to reflect on the railroads in what I have said, for in my opinion they are a much-abused body, and my observation has always been that they are willing to do more for the injured tramp than any one else except perhaps the physician who gets into the case and can't get out.

What I do want to know, and what it seems well nigh impossible to find out, is who I can blame. I've lots of surplus steam I want to work off if I can only find the culpable party, and the principal object of this paper is to gain information on this, to me, very important and interesting subject.

If no one is responsible it seems to me that some efforts should be made towards fixing the responsibility. It would appear feasible to make some agreement between the railroad authorities and the county or State authorities, whereby such cases could be looked after without the whole burden falling on either party.

Intestinal Obstruction.—Winslow (*Maryland Medical Journal*, September, 1900) says intestinal obstruction is caused by a number of conditions, but in any case it is always characterized by stoppage of fecal evacuation. There are the acute and chronic forms; the former being due to a variety of pathologic conditions, the most common of which are strangulation by bands, by kinks due to adhesions, by intussusception, by volvulus, by foreign bodies, strictures, tumors, and fecal impaction. Usually the patient is in good health and the condition arises suddenly. The most constant symptoms are sudden pain radiating about the umbilicus, vomiting and the usual symptoms of acute indigestion. The bowels may move at first, but soon this ceases and flatus accumulates, distending the abdomen; tympanites, however, does not supervene if the obstruction be situated high up. At first the vomiting is only of the gastric contents, but later becomes stercoraceous. A slimy, bloody discharge from the rectum is suggestive of invagination. The urine is markedly diminished in quantity, due to vomiting of the fluids. The pulse soon becomes rapid and the patient, if not relieved, passes into profound shock. The prognosis is always grave, but Smith is quoted as stating that 80% of patients should recover if promptly treated. Saline and other purgatives may be tried at first, but after 24 to 36 hours if there is no relief laparotomy should be performed. [A.B.C.]

Diaphragmatic Hernia.—Walker (*International Journal of Surgery*, September, 1900) relates the case of A. L., aged 29, who was injured by a falling tree. The symptoms present were characteristic, leading to the diagnosis of intestinal obstruction, with diaphragmatic hernia and strangulation of the prolapsed gut as a possibility. The pulse was 145, weak, thready and intermittent. The dyspnea was marked. The respirations were shallow, rapid and jerky, and 42 to the minute. The patient complained of an agonizing pain in the left breast, which was increased by coughing and deep breathing. The last attacks of vomiting showed stercoraceous material. It was impossible to get a movement from the bowels. The abdomen was very much distended with gas. There was a diminished expansion of the left side of the chest and a tympanitic note at the base of the left lung. The breathing was amphoric. A succussion sound was developed by shaking the patient. The apex beat of the heart was displaced two inches to the right of the normal position. The seventh and eighth ribs were fractured behind on the left side. On operation a knuckle of the bowel was found firmly held in a rent in the diaphragm, and reduction was obtained only by considerable traction. The surface of the lung showed no rupture and there was no blood in the pleural cavity. After the insertion of four interrupted catgut sutures during deep expiration in the rent in the diaphragm, the condition of the patient became so serious that efforts for union were discontinued, and the external wound sewed up. Recovery was uninterupted. The author concludes: In all cases of so-called internal strangulation, the possibility of a diaphragmatic hernia must be considered. When a diaphragmatic hernia is probable, operation is imperative when the symptoms of obstruction are present. In recent cases diagnosed early laparotomy is probably the better operation. In old cases, on account of the difficulty of reducing the gut, ligating the sac, and stitching the rent in the diaphragm, the transpleural route is preferable. If, after making a laparotomy, the gut cannot be reduced, a thoracotomy is justifiable. [O.C.C.H.]

The Spread of Disease in the Garbage-Gathering of Cities.—In all of our hygienic concern and progress it seems strange that, the world over, there is such great carelessness in the gathering and disposal of the refuse of city houses. It is usually stored or rather dumped about cellars and back-yards for a reckless week, in which all the elements necessary to fermentation and putrefaction have ample time to ripen and dry. Then it is mixed and set out on the pavement for the winds to carry to the mouths and noses of all the inhabitants. If the wind happens to be at all active, the dumping into the wagons and carts soon fills the city with the clouds of dust. Then for miles the loose-jointed, over-filled wagons jostle over and scatter a large part of the contents along the streets, until at last, in dumping (perhaps down a long steep), the wind has another opportunity to send abroad all but the heaviest and least noxious portion of the load. Every city permits carpet-beating and rug-dusting, so that all tuberculous or other disease-germs secure every possible chance to find a lodging-place in human throats and clothes, and, if once failing, they are beaten up and resown incessantly until the seed no longer falls upon barren ground. If the health of the community were only a tenth of the importance to our masters that the election of the boss is!

The Sufferings of Animals in War do not seem to cause much solicitude to our antivivisectionist critics. One would suppose that, if sincere, their compassion would strike at the great abuses instead of at the small and unimportant ones. The fact proves that their compassion is not sincere. What is real is the concealed and inexpugnable hatred of Science, and hence the ludicrous much-ado-about-nothing concerning painless vivisection. We chanced recently to come upon one instance out of a hundred that might be brought forward—the shipment of horses from New Orleans to South Africa for the English cavalry service. For thirty or more days the horses are crowded together and compelled to stand in the ship without exercise, and with no possibility of lying down a minute. Imagine the awful torture! The expense prohibits space to permit of any resting. As a result, in every shipload a great number drop from sheer exhaustion, and are trampled and kicked to death by the others. Those that survive are hustled from the ship to the cars and from the cars to the front, where, with cruelties, necessary or not, they

are put to the merciless service which in a few weeks ends in merciful death. All vivisectionists should logically join the antiwar societies and for a thousand years devote all their energies to lessening disgraceful outrages against animal life that are inevitable results of war. To prevent the coincident human suffering would hardly seem to them a sufficient motive, and we therefore appeal to them on behalf of "our brother the horse."

The Menopause Bogey has long been one of the superstitions of medicine. Cooperating with the natural preoccupation of women with the sexual element of their lives, the mystery of hysteria and even of many diseases has served to make practitioners at least assent to the exaggerated importance attached by the lay world to the cessation of a function; as a result the menopause has been credited with an astonishing influence in producing both health and disease. In checking the vogue of the belief in one direction—as to the insanities and psychoses of the menopause—Dr. Chapin (in our issue of August 25) has undertaken a much-needed reform. Strangely enough, to this ending of a function has been credited no end of diametrically opposite effects. On the one hand, to it has been ascribed a multitude of positive assaults upon the psychic and physical organism, while at the same time it has been customary for patients and physicians to promise purely negative results, *i. e.*, relief from another large category of ills by the same mysterious agency. Post hoc has been constantly held as propter hoc, according as mystery baffled therapeutics or as whim and fancy should dictate. The mere ceasing of a function that has been superadded to life at the adult period of life, that is henceforth useless and no longer required, can certainly have little result per se, either positive or negative, upon the organism. One of the principal reasons for the lay and professional blunder lies in the fact that the morbid consequences of eyestrain are not infrequently exaggerated just prior to the menopause, and cease again soon after. Thus arises the confusion of post hoc and propter hoc. The relief ascribed to the menopause is often due to presbyopia with which it happens to occur synchronously. Increasing accuracy of diagnosis and observation, with a progressive science, will, it is hoped, soon lay the ancient ghost of menopausal superstition that has too long worried us.

Carrying the Antivivisection Argument to the Extremes of Absurdity.—Not very long ago in one of the principal inland cities an organization known as the "Educational League," whose membership was composed of teachers both from the public schools and colleges and professional schools, had an open meeting in which the principal subject of discussion was the protection of song birds. It can hardly be supposed that any fair-minded person can be found who objects to proper measures for protecting the lives of the feathered songsters that add so much to the happiness of creation. "But when the sons of God were gathered together, there was Satan in the midst of them;" and so there was the antivivisection crank at this meeting of educators, ready and anxious to rehearse the old worn-out libels against animal experimentation, and especially against the medical profession. The main-spring of his argument on this halcyon occasion was that "every bird and animal has inherent rights that man must respect and which should be guarded by law." The absurdity of a man wearing calf shoes and kid gloves pleading that "inherent legal rights" of birds should be considered, while he forgot the inherent rights of calves and kids to wear their own skins and not be forced to give them up for the ornamentation of mankind, never seemed to occur to him.

The inherent right of superior orders of the animal creation to use the lower orders for their convenience and pleasure has been well recognized in the history of human progress. Humanity demands that that right be exercised with as little suffering as possible, but it must continue to be exercised. Any attempt to set up laws recognizing the "rights" of lower animals as superior to those of man, can but result in ridiculous failure. Pretty soon we shall hear from these extremists, pleas that all insects shall be anesthetized before birds are permitted to eat them; that all fish-hooks shall by law be made aseptic before being used to tempt a fish out of his native element; that farmers shall be restrained by judicial injunction from the cruel destruction of potato bugs, grasshoppers and other happy little denizens of the fields; that mankind (and womankind too) shall discard leather shoes and return to the use of sandals made of rushes, or that they shall adopt the primitive method of tying pieces of gunny-sack about the feet; that all cows shall be paid cash for the milk that humanity has hitherto filched from them without proper remuneration; that no horse shall be driven or forced to pull a load until his legal acquiescence, properly attested, has been placed on file in the courts. "Every animal has inherent legal rights which mankind must respect." Let us have a new crusade with the antivivisection society in the van of the invading army.

Medical Men and Juries.—Within a short time the idea has been advocated that all juries for criminal

cases should be composed of medical men. The argument in support of this proposition is that in many cases the offender has a disordered mind and a diseased brain, and hence none but medical men are capable of dealing intelligently with his case. That a diseased condition of the nervous system is responsible for many crimes no one can question, but that the condition warrants so radical a change in the present jury system seems extremely doubtful. Surely the number of those who commit crime from an insane impulse is not so great as to warrant the presumption that this is the rule, and that we must construct our juries accordingly. The idea that a jury composed of medical men could weigh each case, determine the degree of insanity, if any, and suit the punishment to the degree of criminal responsibility, appears to us wholly impracticable. Perhaps no two persons were ever actuated by absolutely the same motive, and were ever criminally responsible to absolutely the same degree in committing crime; yet human limitations force us to apply the same punishment in many cases. In practical civilized life we are forced to lay down rules of conduct, and whoever violates these is declared guilty of crime, and to merit the prescribed punishment, provided he was capable of appreciating right and wrong at the time of the offence. If a question arises as to his sanity, that, of course, should be determined by medical men; but he is presumed to be sane until evidence arises to establish the contrary. That there are grades of criminal responsibility perhaps none will deny, but to forsake the well-established rule which makes the knowledge of right and wrong the basis for the infliction or withholding of punishment would carry us at once into a maze of uncertainty. If we could bring ourselves to accept the belief that all or any very large percentage of crime is the result of diseased minds, we should then admit the necessity of juries composed of medical men. When the plea of insanity is so frequently used in attempts to shield the guilty criminal we shall be slow to advocate innovations which may give him other loopholes of escape.

Jumping at Conclusions in Regard to Disease-Distribution.—Recently a medical practitioner who had spent some years in South Africa, returned to England and was invited to deliver addresses before several of the London societies in regard to climatic conditions and prevalent diseases in Africa. Among other things that he is reported to have said by the veracious reporters of the medical press was something to this effect: That diphtheria was a disease of rare occurrence at altitudes of 2,500 feet above sea level, and that it was absolutely unknown at altitudes of 3,000 feet and over. From this observation the deduction was drawn that it is impossible for diphtheria to prevail anywhere at an altitude exceeding 3,000 feet above the level of the sea.

Without for a moment doubting the accuracy of the

observations of the South African practitioner, it seems proper to point out that a too sweeping inference has been drawn from them. Because a disease has not as yet been introduced into a particular locality is no reason for asserting that it cannot exist under the conditions or environments of that locality. It is a well-known fact that diphtheria prevails both endemically and epidemically at altitudes far exceeding any noted by the South African observer. Both from Switzerland and America reliable reporters have detailed observations of diphtheria at altitudes of 10,000 feet and over. Some of the most fatal outbreaks of the disease have been observed at Leadville and Georgetown, Colorado, both of which towns are about 10,000 feet above sea-level. From Denver some of the most accurate observations in regard to the prevalence of diphtheria during the past twelve years have been from time to time published in this and other journals, the altitude of Denver being 5,280 feet. From the same city Sewall, Hall, and other observers have published some of the most reliable observations in regard to the development of tuberculosis at high altitudes, while Mitchell and Crouch, of Denver, and Gardner, of Colorado Springs, have published some very accurate observations in regard to the time required for the destruction of virulence of tubercle-bacilli by direct sunlight. These latter observations have thrown considerable light upon the possible acquirement of tuberculous infection in the altitudes and have disposed with some definiteness of the fallacious claims that consumption could not originate in mountain climates. The fallacy of the past has been based upon the assumption that because the disease had not as yet become endemic in newly-settled regions, it never could become so. Time and the development of many cases have served effectually to dispose of many such mistaken ideas in many parts of the world. The original observers who have published the actual facts have in some instances been subjected to somewhat severe criticism by the commercial interests of the various localities that imagine their "glorious climate" is being libelled. But this is also a matter that time will eventually remedy, since the faithful record of the truth is not a libel, nor can commercial interests ever hope to control or to stifle the voice of the scientific investigator.

The Bacillus of Yellow Fever.—At the recent International Congress of Hygiene and Demography, held in Paris, an important paper on this subject was read by Proust and Wurtz. Of the three great epidemic diseases of the tropics—plague, cholera, and yellow fever—the last has attracted least attention in recent years, and its etiology still remains a subject of some debate. The paper of Proust and Wurtz is the latest contribution to the subject, and has been translated by Dr. M. J. Rosenau, of the Marine-Hospital Service, and published in the official *Health Reports* of that de-

partment of the Government. In 1897 Sanarelli announced the discovery of the *Bacillus icteroides* and claimed that it was the pathogenic organism of yellow fever. This discovery has been less widely and brilliantly confirmed than in the cases of the microbes of the two other diseases named. Proust and Wurtz describe the characteristics of the bacillus. It is found in the blood and tissues, but not in the gastrointestinal tract of individuals sick or dead of the disease, and is always associated with other microbes. This latter fact, together with the fact that its presence is very transitory, makes it difficult to recover it. This bacillus survives in nature for a very long time; the surest agent for its destruction is moist heat. It dies immediately in water at a temperature of 65° C. It is anaerobic, and its growth is favored by molds, warmth, moisture, and lack of ventilation. It is especially flourishing in sea-water. It is pathogenic for most of the domestic animals, but birds resist it. Its toxin is extremely active, and in dogs produces the same lesions as the bacillus itself. Sanarelli inoculated 5 persons with a bouillon culture, filtered and sterilized, and produced typical yellow fever with all the symptoms and anatomic conditions. Among those who have confirmed the work of Sanarelli in this country are Geddings, and the commission of the U. S. Marine-Hospital Service. This commission found the bacillus in 100% of cases in Cuba in one year. Proust and Wurtz quote all those who have confirmed Sanarelli both in this country and abroad, and evidently consider that the claims for the specificity of the bacillus are well founded. The experimental disease is almost identical with that in man. The injection of the toxin in man reproduces the symptoms of yellow fever. Further, the serum of persons attacked by yellow fever agglutinates the *Bacillus icteroides*. This specific reaction seems to the authors to be a decisive proof that the bacillus of Sanarelli is the cause of yellow fever. The mode of its entrance into the organism is not yet decided. It is still an open question whether the infection is by inhalation, ingestion, or direct contact. The theory of Finlay, that the mosquito is the carrier of the microbe, has not been established. From the standpoint of prophylaxis less progress has been made than in etiology. Sanarelli hopes to solve this problem by the use of a serum. The difficulty is to make animals tolerate heavy doses of the bacillus and thus to obtain a serum having both preventive and curative power. The authors quote the few results thus far obtained, but these are meager.

The Prophylaxis of Plague.—The Marine-Hospital Reports contain a translation by Dr. M. T. Rosenau of Dr. Calmette's paper on this subject read at the International Congress of Hygiene and Demography, 1900. Two methods are employed. One is by the antipest serum, the other by cultures of the *Bacillus pestis* killed by exposure to 70° C. for one hour. The serum

conveys an immediate and effective immunity, but this immunity, unfortunately, is of very short duration, rarely exceeding 12 or 14 days. The injection is neither painful nor harmful, and the serum retains its potency almost indefinitely. The cost of producing it, however, is great, and the difficulty of inducing persons to accept a vaccination which must be repeated so frequently is a great disadvantage. The other method, known as Haffkine's method, by inoculation of cultures of the *Bacillus pestis*, has the undoubted advantage of conferring a much longer immunity. This method has been applied on a very large scale by M. Haffkine for the past three years in India. The duration of this immunity varies greatly, according to the quality of the culture, and may be from a few days to several months. Dr. Calmette undertook by experiments on animals to determine the duration of the immunity procured by Haffkine's method. He satisfied himself that the immunity after one inoculation of 3 cc. of the bacilli in culture one month old, is not established until after the seventh day. It lasts about three weeks in a guineapig, one month in a monkey. In a rat it lasts longer—as long as three months. From these experiments no conclusions can be applied in the case of man, but as the rat is much more susceptible to plague than is either the guineapig or monkey, and the immunity lasts longer in this animal, it may be inferred, according to Calmette, that a single injection can confer a longer immunity in man than in animals.

Some of the advantages of Haffkine's method are the following: The culture is easily and cheaply obtained. The inoculation causes only a little inflammation and lymphangitis for five or six days. The entire population of a village can be inoculated with ease and rapidity. The one serious objection to this, as to the other, method is the difficulty of obtaining the consent of people to be inoculated. To be effective, the inoculation should be obligatory on a whole population. A grave risk from Haffkine's method is in the fact that during immunization the person is much more susceptible to plague, and if he had already contracted even a mild case the inoculation might be fatal. Calmette demonstrated this fact on animals during the recent epidemic in Oporto, Portugal. Several cases of rapid death from this cause have followed Haffkine's inoculations in India. The heated cultures retain their activity a much shorter time than the serum. In spite of these objections the inoculation of Haffkine's cultures is especially indicated during epidemics, and may limit the disease to its focus. The antipest serum, however, is the only efficacious remedy for the plague after the disease has appeared: in other words, it is curative. As the plague is now an actual menace to Europe and America, it is incumbent, Dr. Calmette thinks, upon every country to arm itself, as France has done, by providing antipest serum for prompt use by all physicians, in order to arrest in the first case a nascent epidemic.

Pneumonomycosis Aspergillina.—This rare affection has recently been described by Pearson and Ravenel (*University Medical Magazine*, 1900), their case being the first instance of its observance in a mammal in the United States. It occurred in a Jersey cow. The disease is a form of parasitism by the mold mycosis, known as the *Aspergillus fumigatus*. It has been observed in Europe not only in birds and mammals, but also in man, and has been experimentally produced. Among men it has been especially observed in the pigeon-feeders and hair-sorters of Paris. The men who perform the operation of "gavage" in pigeons take into their mouths a mixture of millet and vetch-seeds in water and force this mixture into the throats of the birds. The hair-sorters use rye flour to absorb the grease of the hair, in order to enable them to disentangle the knots. The air becomes contaminated, and animals kept in it die. By these two occupations the workmen may become infected with this fungus, which is very widely disseminated in nature.

The disease was first observed by Mayer, in 1815, in a jay. Rivolta, in 1857, reported the first case of mycotic infection in one of the lower animals—a horse, which had a tumor of the pharynx in which mold mycelium was discovered. In 1842, however, Hughes Bennett had found a fungus in the sputum of a phthisical patient; but Shuyter, in 1847, was the first to clearly demonstrate the aspergillus as the fungus in a case of pneumonomycosis in man. Since that time some important contributions, notably by Renon, of France, and Saxer, of Jena, have appeared, but the disease is still an uncommon one in man and practically unknown to most physicians.

In Pearson and Ravenel's case, in a Jersey cow, the animal had been failing for six months, with progressive emaciation and a bad cough. As tuberculosis was suspected, the patient was given tuberculin, but gave no reaction. She was removed to the Veterinary Hospital of the University of Pennsylvania, but did not respond to treatment, and died, with marked symptoms of pulmonary involvement, a few days after admission. The authors present a very elaborate and well-illustrated report of the pathological findings, in a paper which is evidently a most valuable contribution to the literature of this rare disease. The mycelium was found in numerous dark-red nodules, scattered through the lung, the surrounding lung-tissue being normal in color and appearance. The fruit-heads of the fungus, with myriads of spores, were easily demonstrable. The diagnosis was thus readily made, and it was afterwards confirmed by cultures. A new growth was promptly obtained by transferring a portion of the mold to a suitable medium. Its characteristics are described in full by the authors. The aspergillus makes no toxin, and its pathogenic action is simply that of a trauma. The foci readily multiply. The authors conclude that their case was one of primary, not secondary, aspergillosis, from the

fact that the aspergillar nodules were by far the most extensive lesions, only a few tuberculous nodules being found, these being confined to a portion of one lung.

The S. P. C. A. and the Rockaway Hackmen.—We quote from the *New York Sun* of September 25:

When the season is ended the hackmen of Far Rockaway make it a practice to meet at some nearby place and have a race in which all of the horses they own are entered for a cash prize raised from entry fees. These prizes in nearly every case exceed the market value of all the horses entered. The race this year was planned to be held at Woodmere, but the residents there, who knew from past experience the nature of the event, organized a movement to arrest the whole crowd of hackmen. The hackmen learned of this move, and went to "Bill" Smith's place, on the Merrick road, between Valley Stream and Rosedale.

The races were held on the open road, and the wretched animals were beaten and lashed into the semblance of a gallop which for some was the last. One of the horses fell dead in the race, while another fell dead a few moments after. Two years ago the race was held on one of the main streets of Far Rockaway, and when it was over three dead horses were left lying where they fell.

There are about forty hackmen who do business in Far Rockaway during the summer season, and the majority of them drive animals that are scarcely fit for any service. Broken down, half-starved, lame and foundered animals are kept in harness twenty hours out of the twenty-four. When the season closes many of the horses are so worthless that no one will take them for a gift. So the hackmen turn them loose to die on the highway. Last year a herd of five cast-off horses was found wandering about on the verge of starvation and were taken off into a lot and shot. Throughout the summer many complaints have been lodged against the hackmen for cruelty to animals and in several instances arrests have been made. The S. P. C. A. has had its attention drawn to the state of affairs in Far Rockaway during the summer, but no officer was sent to that section. An effort was then made to raise \$300, the amount necessary to pay the salary of an officer for the four months of the summer season, but it failed.

We wonder if the devoted members of the S. P. C. A. will excuse the poor hackmen by saying that it is all the fault of the medical vivisectionists. But how will they manage to excuse the S. P. C. A.? *Quis custodiet ipsos custodes?*

Medical Sermonets No. 22. The Antinomy of Life's Valuation.—Students of speculative philosophy remember with peculiar pleasure Kant's treatment of antinomies or the proofs by irrefutable logic of two seemingly absolutely contradictory statements. Thus the theorem that the world began in time and that it had no beginning are equally provable or disprovable, although one must be false if the other is true. But Kant did not set forth one antinomy which is encountered every day in private practice by the physician. This pertains to the personal valuation of life. To some patients this life is of infinite value and the thought of it becomes a disease and a monomania, while with others a furious recklessness takes the place of the engrossing egotism. A physician may in the same hour pass from the house of the ludicrous hysteric who has been 20 years in bed nursing her imaginary ills, to the suicide whose life is saved only by outwitting his hundred tricks to kill himself. Between these two extremes there are innumerable degrees and variations of life-valuation, shading into each other by subtle differences which confuse us and seemingly contradict all our judgments and theories. But such antinomies are not the only ones. The most perplexing

and irritating are those we encounter irreconcilably clashing in a single patient. We find that we are sometimes confronted by an illogic love and contempt of life exhibited by one person. A physician in New York tried to get the consent of several patients to be examined, periodically and systematically whether healthy or ill, in order to detect the beginnings of disease and insure better prophylaxis, but he soon found that they cared nothing for their physical condition ten years from now; all they desired was to follow fashion or to gain the fortune and the success now, and to be tided over the present-day difficulty, however life might be shortened or crippled. Every oculist is daily angered by the utter indifference of women to future injury or ruin of the eyes, betrayed in the refusal to wear spectacles. Most English people would rather wreck health and eyesight than wear a glass—unless perhaps it were the fool's monocle. The awful vogue of the pain-deadening quacks and syndicates vividly illustrates how much both people and profession care for stopping symptoms and how little they are concerned about the etiology and the causes of disease.

As with all antinomies there must be some genuine harmonizing and solution either theoretic or practical or both, so here as to the valuation of life there must be a wise and correct estimate. The disregard of disease and life by the professional tramp, the criminal, the drunkard, the loafer, the suicide, the quack, and the nostrum-vender, cannot be right any more than the self-coddling of the hysterics and the nostrum swallowers. It cannot be wise to sacrifice future health and longevity for the riot and the rout of luxury and the power of today's recklessness. The valuation of life must be made rational and consistent. Even the medical profession is in danger of erring as to an overvaluation of life in the case of monstrosities, idiots, and hopelessly diseased sufferers, or as to an undervaluation in the rage for rapid operation, in some past vivisection experiments, etc., while a contradictory estimate is practically illustrated in our oft exemplified intemperance as to cocaine, morphin, alcohol, banquets, hospital abuse, college politics, etc. To increase the total of healthy and moral life of the world is probably the simplest and best law of conduct. Even the purest self-sacrificing love may be senseless and irrational, and the most splendid science may be cruel and immoral. It is not impossible to blend the two in a consistent and dignified life motivated by philanthropy and governed and directed by a reason that is erudite and scientific. An intellectualized love, a scientific religion, a gracious reason, a preventive medicine—these are not meaningless terms incapable of practical realization. The ideal physician is he who best realizes them in daily work and who best teaches his patients the proper valuation of their lives.

Operative Treatment of Mastoid Inflammation.—Bradford (*Transactions International Otological Congress*, August, 1899) speaks of the great increase in the number of operations for the relief of mastoid inflammation, and he thought it augured well; also of the fact that the operations are now done by the otologist and not by the general surgeon. He considers there are but 2 signs which indicate operation: local tenderness over the region of the mastoid antrum (not over the tip of the mastoid process); a sagging of the upper and posterior wall of the external auditory meatus, close to the membrana tympani. The author says when intracranial complications exist, operative treatment offers the only means of relief, and in his experience this is usually attended with good results. He operated on 13 cases of thrombosis of the lateral sinus, with 2 deaths; and 14 cases of epidural abscess, all of which recovered. He discussed at some length the technic of the operation and the preparation of the patient for operation. [A.B.C.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Calendar of Meetings of Philadelphia Medical Societies for the week ended October 6, 1900:

Wednesday, October 3—College of Physicians.

Tuesday, October 2—College of Physicians, Section on Otology.

Thursday, October 4—Obstetrical Society.

Pennsylvania Hospital.—A new entrance building is being constructed at a cost of \$60,000.

Bee Sting Causes Death.—Blood-poisoning followed the sting of a bee and caused the death of a man in Paterson, N. J., recently.

Impure Water Caused Typhoid.—Typhoid fever is prevalent in Pottstown. The local Board of Health has made an investigation, and traced the malady to the impure well-water.

Poisoned by Jimson Weed.—William Noll, an 8-years-old boy of Philadelphia, has been poisoned, and it is reported may lose his reason, because he ate the pods of the jimson weed.

Public Baths to Close.—The 9 public bathhouses, which were opened early in June, have closed for the season. The attendance during the summer has far eclipsed that of any previous season since the institutions were established.

Conjunctivitis Caused by Baths.—New York has had a visitation of this disease and now it is epidemic in Philadelphia. Physicians believe the public baths are to blame for the disease, or the towels that are used at these baths.

Death from Circumcision.—An infant in Philadelphia recently died from hemorrhage following circumcision by a rabbi. A physician was called after unsuccessful efforts had been made for 2 hours to control the hemorrhage. The child died 5 hours after the physician was called to see the case.

A Victim of Brass Poisoning.—A patient died at the Williamsport hospital recently from brass poisoning. It is reported that his system had been so impregnated with the poison that his teeth had become oxidized, and the perspiration as it oozed from his pores was greenish in color. He was an expert metalworker.

An Aged Man Undergoes Operation.—Recently a man in his ninety-fifth year was operated upon for strangulated hernia by Dr. De Forest Willard, assisted by Dr. Ludington, at the Presbyterian Hospital. The man made a speedy recovery; has been perfectly well since; does not wear a truss, and is now 96 years of age.

Pollution of the Navesink.—The residents of Red Bank, N. J., have complained to the New Jersey Sewerage Commission that the Navesink River is polluted by sewage. It is said that oysters taken from the river are unfit to eat. The property-owners are in favor of building a sewage-disposal plant if the town commissioners will aid them by an appropriation.

Vessels Held at Quarantine.—The Italian barks *Gregoria*, from Genoa, and *Nuora Eleonor Madse*, from Marseilles, have been detained at the State Quarantine Station, pending the examination of a lot of cotton waste and bagging which the vessels bring as cargo. The ravages of the plague in Mediterranean ports have made the quarantine officials careful of what they admit to this port.

Seashore House in Debt.—The Children's Seashore House in Atlantic City closed last week, when 60 mothers and children left the institution, the last of more than 1,800 cared for during the summer. No room could be found for 375 applicants during the 3½ months the institution was open, and lack of funds made a longer season impracticable. There is even now a deficit of nearly \$1,000 to be provided for.

Bequests to Charity.—By the will of the late John P. Murta, of Philadelphia, his nephew and niece are devised \$2,500 each in trust, with reversion of the principal, upon their deaths, in the Society of St. Joseph for Educating and Maintaining Poor Orphans and the Little Sisters of the Poor, respectively. The residue of the estate is devised to Archbishop Ryan for the Catholic Protectory for Boys, situate at Fatland, Montgomery County.

Charitable Bequests.—The will of the late Dr. Jacob M. DaCosta, of Philadelphia, contains bequests of \$5,000 each to the Pennsylvania Hospital, the Children's Hospital in Philadelphia, the College of Physicians, and the University of Pennsylvania, and \$1,000 to the Sunday Breakfast Association of this city. Dr. DaCosta devised his medical museum to the Jefferson Medical College and his medical library to the College of Physicians.

Adulterators of Food Held.—The heads of the firm of Burns, Metzger & Co., charged with having sold adulterated spices, have been held in \$1,000 each for a further hearing. Under analysis starch and small bits of wood were found in black pepper, manufactured by the firm, while the white pepper was found to contain a substance resembling ground olive seeds. Cinnamon was adulterated with starch, ground bread crusts and the bulbs of olive seeds.

A free scholarship in the Philadelphia College of Pharmacy has just been established whereby meritorious students may, after successfully passing a competitive examination, and producing satisfactory evidence of ability before the committee of the college, become entitled to free tickets to all the lectures. The scholarship thus established embraces all the branches taught in the college, and has been created through the desire of Mr. Henry G. Keasby and Dr. Richard V. Mattison, both of whom are graduates of the college. All persons desiring to avail themselves of the privileges of the scholarship should address the Dean of the Faculty, Prof. Joseph P. Remington, at once.

The Company Doctor.—There is one feature in the present struggle of labor against capital which is seldom mentioned and which, if the truth is reported by the lay papers, is nothing more or less than robbery. It is that of the company doctor. Every married miner is charged 75 cents per month, while the single man escapes with 50 cents. Taking the Markle operations as a basis, and averaging the 2,400 employes at 50 cents each, the company gets \$1,200 monthly, but the physician does not receive this amount. At Jeddo there are 3 physicians. The chief of this staff receives about \$200 per month, while the others receive but \$50 per month. This leaves \$900 that monthly reverts to the company.

Mining Fatalities.—James T. Roderick, chief of the mining department, is about to issue his annual report, which will contain some very interesting data. The ever-increasing number of lives lost in the mines will attract attention. Mr. Roderick's figures show that during the decade from 1870 to 1880 the deaths averaged 215 annually, between 1880 and 1890 the number was 311 annually, between 1890 and 1900 the average per annum was 439. The report attributes this increase of loss of life to two causes, viz.: First, the greater depth of the mines; and, second, the large percentage of non-English speaking, unskilled and unintelligent men employed in the mines in more recent years. Mr. Roderick apprehends that no improvement will be experienced during the next ten years.—[Wilkesbarre Record.]

Dr. Alfred Stillé, who for nearly 20 years was professor of theory and practice of medicine at the University of Pennsylvania, died at his home in Philadelphia September 24, aged 87. Dr. Stillé was graduated from the University of Pennsylvania in 1832 and as doctor of medicine in 1836. Between this date and 1839 he pursued his medical studies in Paris and in other European capitals. From 1844 to 1850 he lectured on pathology and the practice of medicine to the Philadelphia Association for Medical Instruction. In 1849 he was appointed physician to St. Joseph's Hospital, and in 1854 was elected professor of theory and practice of medicine in the Pennsylvania Medical College and filled that chair until 1859, when he was chosen to occupy a similar chair in the University of

Pennsylvania. This position he held until 1884, when he became professor emeritus. He was president of the American Medical Association in 1867, of the Philadelphia College Medical Association in 1862 and of the College of Physicians of Philadelphia in 1885. From 1865 to 1871 he was physician and lecturer on clinical medicine in the Philadelphia Hospital. The honorary degree of doctor of laws was conferred upon him by the Pennsylvania College, at Gettysburg, in 1876. He was the author of numerous medical and scientific publications.

Vital Statistics of Philadelphia for the week ended September 22, 1900:

Total mortality	356
Disease.	Cases. Deaths.
Inflammation of appendix 5, bladder 2, brain 8, bronchi 4, kidneys 14, liver 1, lungs 16, heart 2, peritoneum 4, stomach and bowels 17	73
Lungs—tuberculosis of 39, hemorrhage of 1, edema of 1	41
Heart-disease of 33, fatty degeneration of 1, neuralgia of 4	38
Debility 2, marasmus 16, inanition 18	36
Cholera infantum	21
Apoplexy 9, paralysis 8	17
Carcinoma of bowels 1, liver 3, rectum 1, stomach 4, uterus 3, lymphadenoma 1, brain tumor 2, abdominal tumor 1	16
Diphtheria	101 15
Convulsions	12
Casualties	9
Cirrhosis of liver	9
Whooping-cough	6
Typhoid fever	41 5
Septicemia	4
Old age	4
Drowned	4
Suicide—carbolic acid 1, hanging 1	2
Scarlet fever	12 2
Pelvic abscess, alcoholism 1, asthma 1, anemia 1, aneurysm of aorta 2, burns and scalds 1, cholera 1, diarrhoea 1, hip disease 1, dropsy of chest 1, puerperal fever 1, remittent fever 2, hemorrhage of stomach 1, hernia 1, obstruction of bowels 1, rheumatism 1, suffocation 1, sunstroke 2, teething 1, ulceration of stomach 1, gunshot wounds 1.	

NEW YORK.

Bequests to Charity.—By the will of the late Mary Ann Turner, of Brooklyn, the St. Christopher's Home for Children will receive \$2,000 and the Seney Hospital \$500.

City Physician Suspended.—Dr. McDonald, of the Metropolitan Hospital on Blackwell's Island, has been suspended for 30 days for having turned away a tuberculous individual in a dying condition.

State Hospital for the Tuberculous.—The special commission appointed by Governor Roosevelt has selected Lake Clear as the place to erect the State Hospital for tuberculous individuals, subject to the approval of the Forest Preserve Board and the State Board of Health. It is one of the most salubrious places in the Adirondacks.

Wants \$10,000 Damages.—A suit for \$10,000 damages has been instituted by Dr. Elias P. Iliff against Dr. C. C. Carroll, both of New York. Dr. Iliff claims that his attitude toward tuberculosis has been misrepresented by Dr. Carroll and his usefulness as a physician impaired by his remarks. He has always taught that tuberculosis is neither infectious nor transmissible.

Zeta Phi Antedated.—A letter from one of our correspondents states that the Beta Phi Fraternity of Syracuse University is not the first and only woman's medical fraternity in this country, that at least three of like import antedate it, namely one at the University of Buffalo, one at the University of Michigan, and another at the Northwestern University Medical School.

The "man with the iron mask" has just died in Bellevue Hospital of Bright's disease. He lost his nose while a child, and the hospital physicians made him another from one of his own fingers, after a remarkable operation. The result was passable, but he developed a great aversion to

having people see his features, and took every possible means of concealing them. It was this that gave him the title of "the man with the iron mask."

Victim of Patent Bitters.—A New York undertaker appeared at police headquarters in Denver, Col., recently, attired in overalls, his hands calloused from hard work, and asked to have his wife communicated with and told of his condition. He said he remembered nothing since July 4, which he spent in New York, until he suddenly realized that he was in a strange city. He attributes his mental lapse to excessive use of patent bitters prescribed by a physician as a tonic.

A Protest Against Old Paper Money.—A protest has come from Brooklyn to the New York Board of Health against the reissue and use of old bank notes and Government paper money. The statement has been made that the banks and general Government are reissuing bank notes which have been passed from hand to hand until they are in a filthy condition and are the means of conveying contagious diseases from one to another. The matter has been taken up by Secretary of Treasurer Gage.

Dr. Lewis A. Sayre, who has been called "the father of orthopedic surgery," died at his home in New York, September 21, aged 80. He was born in Bottle Hill, N. J., was graduated from the University of Pennsylvania in 1839 and from the College of Physicians and Surgeons, New York City, in 1842. Dr. Sayre was prosecutor to the professor of surgery in the College of Physicians and Surgeons and professor emeritus to the same institution when he died. He was one of the founders of the Bellevue Medical College and of a number of medical societies. In 1871 he went to Europe, where he was chosen an honorary member of many medical societies in England, Russia, and Sweden. He has written several standard medical works.

NEW ENGLAND.

The Connecticut Children's Aid Society, of Hartford, received \$5,000 by the will of the late Elisha Turner, of Torrington.

Charity Receives \$50,000.—By the death of the widow of Judge Gafney, of Rochester, N. H., \$50,000 has been left in care of trustees to be used for any public, charitable, or benevolent purpose in the State of New Hampshire that they may think best.

Another Broken Neck.—Holbrook Mann, who met with an accident while diving August 7, and who was operated upon in Portland (Me.) Hospital, has been removed to his home. Two vertebrae were found crushed and pressing on the spinal cord. The fragments were removed. The case is similar to that of Walter Duryea.

Hartford Retreat for the Insane.—Dr. Gurdon W. Russell, of Hartford, who has been connected with the Retreat for the Insane in that city for nearly half a century, has presented to the Retreat his Maplewood Lodge on Cedar Mountain with 9 acres of land. The place will be used as a summer home for the inmates of the institution. Dr. Russell also gave \$500 to be used in fitting the house for its new purpose.

New Hampshire Surgical Club.—The annual meeting of the New Hampshire Surgical Club was held at the Farragut House, Rye Beach, September 6, 1900. Two very interesting and able papers were read by Professor J. M. Gile, of Hanover, and Dr. J. C. Irish, of Lowell, Mass., who was present by invitation, on **The surgery of the gall-bladder and bile-ducts**. The presidential address was given by Dr. George D. Towne, of Manchester. Dr. Ira J. Prouty, of Keene, was elected President.

Board of Health and City Physician.—A new Board of Health will be appointed in Springfield, Mass., one member of which will be a physician. The duties of the body are to be broader than those of the present board. The duties of the city physician have been considered, and in addition to the present work will include the examination of applicants for the fire department, the attendance on prisoners or members of the police force, and the examination of persons bringing suit against the city for sustaining physical injuries.

CHICAGO AND WESTERN STATES.

The new hospital which is being erected at Washburn, Wis., will be ready for occupancy, October 1.

St. Luke's Hospital.—The corner-stone for the addition to St. Luke's Hospital, San Francisco, was recently laid.

Diphtheria Claimed 7 Children.—Within a year 7 children of one family in Wenasha, Wis., have died of diphtheria.

Dr. Hensley Acquitted.—Dr. E. T. Hensley, of Okmulgee, I. T., who has been on trial there in the U. S. Court for murder, has been acquitted.

Mount Sinai Hospital.—A hospital in Chicago bearing this name has been incorporated by Drs. Rudolph Menn, George M. Silverberg, and Adolphus E. Berting.

The Denver Health Department has discharged its milk inspector and meat inspector, and closed the Steele Hospital for Infectious Diseases, for lack of funds.

Leaps From Window.—A patient in the City and County Hospital, San Francisco, recently jumped from the window of his ward in that institution, and was killed.

Beatrice Institute for Feeble-Minded.—Dr. B. F. Lang, superintendent of the Institute for Feeble-Minded in Beatrice, Nebraska, has been removed and Dr. Dearing has been appointed in his place.

Extracted the Wrong Tooth.—A suit to recover \$1,000 damages has been instituted by a woman of Portland, Oregon, against a dentist of that city because he extracted a sound tooth in place of a decayed one.

Hospital Corner-Stone Laid.—The 5 corner-stones of the new building to be added to the Deaconess' Hospital, at Bloomington, Ill., were laid recently with appropriate ceremonies. The new building will cost \$20,000.

Asylum Contract Inquiry.—The plumbing contract for the new buildings at the State Asylum for Feeble-Minded Children at Lincoln, Ill., is being investigated by the grand jury. The contract involved the expenditure of \$54,000 of State funds. The new buildings when complete will cost \$200,000.

Veterans' Home.—Walter Houston, an old soldier, who died recently in Utica, Wis., bequeathed \$12,000 to the Veterans' Home at Waupaca, Wis. Mr. Houston visited the Home some time ago disguised as a tramp soldier, and he was so kindly treated that he determined to remember the institution when he died.

Deformed and Crippled Beggars to be Removed. A medical society in Cleveland has started a movement for removing offensively deformed and crippled beggars from the street. The number has greatly increased in recent years and the doctors believe that the public display of deformity is injurious to the community.

For Sick Soldiers.—Winfield Scott Garrison Regular Army and Navy Union, Cheyenne, Wyoming, has passed resolutions and placed the matter before the senators and congressman of the State, looking toward the relief of any soldier or sailor of the army and navy, honorably discharged, who may be so unfortunate as to become ill without friends or means to prevent such a one from becoming a public charge.

Five Boys at One Birth.—A remarkable birth is reported from Mary's Home, near Jefferson City, Mo., where Mrs. Henry Smith gave birth to 5 baby boys at one time. They are reported to be well and weigh a total of 30 pounds. Smith has been married less than 7 years and is the father of 16 children. Only one time has there been born a single baby. The others are 2 pair of twins, 2 pair of triplets and the quintette.

Glanders Among Cavalry Horses.—Glanders has again broken out among the horses at the Presidio in San Francisco and 17 of the diseased animals were shot. Some

weeks ago the disease attacked the horses of the Ninth Cavalry, and to prevent its spread 150 fine animals were shot and their bodies buried. Several animals, however, were held for observation, and recently the suspicious cases were submitted to a final test, with the above results.

Blow to the Pure Food Law.—The new pure food law was given a death blow recently when Judge Smith, of Chicago, ruled that no conviction can be made unless it is shown that the storekeeper had guilty knowledge of the selling of impure food. Representatives of the State Pure Food Commission expressed their disappointment at the result of their efforts to enforce the law, and they admit that punishment can be meted out in but few cases, because it is almost impossible to show a guilty knowledge on the part of the storekeeper.

A Doctor's Carrier Pigeons.—The success of an experiment in the use of carrier pigeons to carry messages from a sick-room to the doctor's house, is announced by a daily paper. Dr. H. G. Leisenring, of Wayne, Neb., has been the experimenter. He has trained 20 carrier pigeons, and when he makes his round of professional visits he leaves one bird at each house where his services may be required in an emergency. When the doctor is needed one of the pigeons is released, and carrying the message tied to its legs flies at once to the doctor's house.

State Health Board Superior to Local Boards.—After an unpleasant contest between the State and City Board of Health of Denver, which threatened to culminate in spirited litigation over the question as to whether the State Board had authority to demand from the City Board reports of all contagious diseases, the latter announced that the State Board was vested with such a prerogative by law. The reports which have been withheld since June 7 will therefore be sent in to the State Board with due regularity hereafter. In view of the fact that the statute vests the State Board with authority to suppress contagious diseases by quarantine, and in view of the fact that the district attorney had threatened a suit for a penalty under the statute, it was deemed wise to acknowledge the supreme authority of the State officials.—[*Colorado Medical Journal*.]

The Physicians' Business Association, recently organized in Detroit, would be more appropriately called the Detroit Physicians' and Surgeons' Union No. 1, the *Tribune* of that city says. In intent it is a union, its chief object concerning wages. "If an employer refuses to pay his doctor, or insists on compensating him with wages below the union scale," the *Tribune* explains, "the doctor will strike, just as the miners have struck—that is, he will refuse to treat him any more. All other union doctors must likewise strike, and refuse treatment to the employer who refuses honest pay for honest service." At the first meeting of the association there was violent talk on a proposition to boycott doctors who should refuse to join the association. A section of the constitution offered for approval went so far as to provide that association members should refuse to recognize as physicians, either personally or professionally, such boycotted doctors. There was at first some objection to so radical a measure, but the vote showed that the sentiment favored it in overwhelming measure.

A Study of Suicide.—Public attention has been called of late to the increasing number of suicides in Chicago, but if the mean annual rate shows a tendency to advance it is merely obeying a rule which appears to be common to most civilized countries. Tables of statistics indicate only one exception to this rule. In Norway the annual rate per 1,000,000 of the population has decreased steadily from periods beginning with 1831-35 and ending with 1881-90. The range is from 108 in the first period to 67 in the last. The decrease coincides with the decrease in the consumption of alcohol. But elsewhere this mania is increasing to an alarming extent. In France the rate per 1,000,000 per annum went from 98 in the period 1811-60 to 212 in the period 1885-88, and it was almost steadily progressive. Saxony, the most suicidal of all countries, went from 223 in the first period to 333 in the last. Italy and Ireland, have the lowest rates, but this is explained in great measure by a large emigration. In general the increase of the rates of suicide is attributed to conditions which are the result of modern progress.

Patent Medicine Prices and the Importation of Opium.—At the Chicago Convention recently, the Proprietary Association of America united with the Wholesale Druggists' Association, the National Retail Druggists' Association, and the American Pharmaceutical Association in a close agreement to uphold the retail prices of proprietary medicines and drugs. As a result of this action all proprietary medicines will be put upon the market at the prices listed, and not at a reduction of from 20 to 40%, as department stores and distributing concerns are in the habit of doing. The Committee on Adulterations made a report which caused something of a stir. Instances of adulteration were given as follows: Some olive oil, branded with imported labels, is cottonseed extract manufactured in Eastern cities; Lehigh coal dust is palmed off as powdered antimony; soda is substituted in borax; essential oils in a pure state are almost unknown to the market, and practically cannot be obtained. It was the unanimous sentiment that proper labels, as well as purity, should be insisted upon, and that the Brosius pure food and drug bill, introduced into Congress last session, should be passed. Importation of opium into the United States free of duty was advocated by the National Wholesale Druggists' Association. The plan to abolish the duty on the drug was urged as a means to make its use more available and save the druggists \$300,000 a year now paid to the Government. Opium was declared to be discriminated against by the Government in a false belief that a heavy duty on the drug discourages the opium habit.

SOUTHERN STATES.

Sale of Tobacco Prohibited.—The State Legislature of Louisiana has passed an act forbidding the sale of tobacco, cigarettes, etc., to minors, which law is now in force.

Somnambulist's Neck Broken.—John Muelhausen, of New Orleans, recently walked in his sleep from the roof of his house, and fell 40 feet to the pavement. His neck was broken by the fall.

Southern Surgical and Gynecological Association.—The meeting of this association will be held in Atlanta, November 13, 14, and 15, under the presidency of Dr. A. M. Cartledge, of Louisville.

Texas Favors a Board of Health.—At a representative political meeting recently held in Texas a resolution was passed favoring the establishment of a Board of Health instead of the present system of one health officer.

Victim of Christian Science.—The Coroner's jury recently investigated the death of a boy at New Berne, N. C., and rendered a verdict that he died of improper treatment and neglect. The boy was not allowed any medical attention, but was left in the hands of a Christian Science "healer."

The Medical College and Quarantine Station at Galveston.—Arrangements have been perfected for the immediate repairing and refurbishing of the Medical College at Galveston. The session will be opened November 15 with the same faculty. The State will rebuild at once on its old site, and in the strongest manner possible the quarantine station at Galveston.

Richmond (Va.) News.—The new annex now being built to the Virginia Hospital, will bear a tablet inscribed in the honor of Hunter McGuire and will be known as "The Hunter McGuire Annex."

Dr. Stuart McGuire has assumed full control of St. Luke's Hospital, so long and well conducted by his father.

Virginius Harrison, A.M., M.D., has been elected to the chair of *Materia Medica* and Therapeutics in the University College of Medicine.

Georgia Pasteur Institute and Laboratory.—The charter members of the Georgia Pasteur Institute and Laboratory met in Atlanta September 21 and elected the following officers: President, Dr. Henry R. Slack, LaGrange; vice-president, Dr. J. H. McDullie, Columbus; secretary, Dr. Claude A. Smith, Atlanta; treasurer, Dr. C. D. Hunt, Atlanta. This institute has the endorsement of the Medical Association of Georgia. In addition to using Pasteur treat-

ment for prevention of hydrophobia they propose to establish one of the best equipped pathologic and bacteriologic laboratories in the South, and hope to be open by November 1.

The Tri-State Medical Society of Alabama, Georgia, and Tennessee will hold its twelfth annual meeting in Chattanooga, Tenn., October 11, 12, and 13, during the reunion of the Army of the Cumberland and the Spanish-American War Veterans. One fare for the round trip has been granted by the Southeastern Passenger Association and will be given, doubtless, by the other passenger associations which will act on the matter shortly.

Embalmers must Qualify.—The Louisiana State Board of Health has recently issued public notices to the effect that on and after September 1, 1900, those wishing to practise embalming in the State of Louisiana must pass a satisfactory examination before a commission appointed by the Board. Those, however, who have actively practised embalming for 5 or more years previous to above date are exempt from examination, and may register if recommended by 2 reputable physicians. D. W. G. Owen and Dr. Arthur Nolte were recently reappointed members of the State Board of Health.

Diseased Cattle Seized.—The Maryland State Board of Health has been engaged for several weeks in a study of the quality of animals and meat at Claremont Stockyards and Abattoir. Recently 3 animals with actinomycosis were seized by the Board. Two of them were in a weak and emaciated condition. It is of great importance that the citizens should be protected by systematic daily inspection of stockyards and slaughterhouses. The board has but one inspector, and his duties are so many and various that he can devote but little time to this particular work. The examinations should begin with the live cattle. This would eliminate the animals which are obviously unfit for food. But those about which there may be some doubt must be inspected after death.

Sanitary Conditions at Galveston.—The Board of Health and the leading physicians state that no disease of an infectious character has yet made its appearance at Galveston, and none was expected under the vigorous measures of sanitation in vogue. The sanitary condition of the city is daily improving, except in the vicinity of the mass of debris cast up against the southern part of the city. The Health Board is positive in declaring that not more than the usual amount of sickness will follow the awful calamity. Dr. Wertenbaker has asked to be relieved of further duty, as the Board of Health had the situation well in hand and there was no further use for the Marine Hospital's services. The work of distributing relief to the destitute, while daily getting upon a more systematic basis, is exasperatingly slow to the thousands of applicants of all ages, color, and condition, that stand in long lines at each substation for hours before their time comes to get their daily supply.

For the Sick and Injured at Galveston.—The Marine-Hospital Service, which is working in conjunction with the Board of Health at Galveston, has established a hospital on the beach. There the sick and wounded, now sheltered in unsanitary places throughout the city, will be taken for treatment, whether they wish to go or not. This hospital will be under the direction of physicians of the Marine-Hospital Service, who will be assisted by a corps of trained nurses. The hospital will consist of 300 comfortable tents, and will be thoroughly equipped in every respect for the treatment and comfort of the patients. The revenue cutter *Winona* has arrived and has been placed at the disposal of the Board of Health for the removal of the sick and wounded who are able to leave the city for interior points. Sickness of the malarial type is becoming quite prevalent among the sufferers, and considerable apprehension is felt that it may assume a more serious form.

Orleans Parish Medical Society.—At the meeting of September 8 there was a general discussion on new drugs to be introduced into the United States Pharmacopeia of 1900. A list was formulated to be forwarded to the Pharmacopeia Committee, care being taken not to recommend any preparation of a strictly proprietary nature.

Dr. T. S. Dabney reported a case of anthrax treated by injecting initial lesion with pure carbolic acid. In this instance the lesion was situated on the lower lip; and after the sloughing resulting from injection, constitutional symptoms began to abate; with ultimate recovery. Dr. Dabney stated that he had for many years treated simple carbuncles by the same method, with almost constant success. Dr. Dupaquier and other members related failures from the same treatment of carbuncle. Dr. S. P. Delaup's case of ligation of innominate artery for double aneurysm—reported in brief before the society immediately after the first operation—died from asthenia and shock after secondary operation, having survived the first operation 21 days.

MISCELLANY.

Havana sewerage work will soon begin under the direction of the Michael J. Dady Company, Brooklyn contractors.

The American Public Health Association will meet at Indianapolis, October 22-26, instead of the first week of the month, as originally arranged.

Unlicensed Medical Practitioner Jailed.—Dr. Preuss, of Williams, Arizona, has been found guilty of practising without a license. He pleaded guilty, was fined \$100 and sentenced to 100 days imprisonment.

Opium Seized in Havana.—The customs official in Havana seized 1,400 kilos of opium, which was being smuggled into the city packed in tins labeled sausages. The opium, which is worth about \$20,000, was confiscated.

Peary's Relief Boat Lost.—The *Lily of the North*, which left Halifax last month with supplies for the Peary Arctic expedition, is lost. The loss is reported from Cape Breton, but nothing additional save that the crew were saved has reached here.

The "Relief" at Nagasaki.—The hospital ship *Relief* has arrived at Nagasaki, Japan, from Taku, with sick and wounded soldiers from China. They will be brought to the United States on the first regular transports from Manila touching at Nagasaki.

Duties of Acting Assistant-Surgeons.—An opinion has been rendered from the office of the Judge-Advocate-General of the Army to the effect that acting assistant-surgeons of the Army may be detailed to duty other than that strictly professional.

Hospital Report from China.—The following cablegram has been received from Surgeon Perley, at Nagasaki, Japan: "Will send 41, including 3 officers, to the United States, 84 remaining; 141 sick in hospital at Peking; 125 at Tien-Tsin; many of them mild."

Smallpox in Alaska.—The entire territory of Alaska has been declared to be smallpox infected, and all vessels coming to Port Townsend, Wash., from Alaska will be inspected. Heretofore vessels arriving from Cape Nome, St. Michael and Dutch Harbor have been under quarantine regulations.

Hospital-Ship at Wei Hai Wei.—A dispatch from the American hospital-ship *Maine*, dated Wei Hai Wei, announces the arrival there of 2 additional surgeons from America, thus completing the medical staff. The *Maine* will remain at Wei Hai Wei. Sick and wounded men are already arriving on board.

Dentist for Guam.—The Surgeon General of the Navy has arranged to send to Guam a dentist to treat the teeth of the men at that naval station. There has been much complaint from sufferers at Guam, and the services of a dentist are greatly needed. The dentist was enlisted as a hospital steward at \$60 per month.

Obituary.—HENRY L. SNYDER, of York, Pa., September 16, aged 74.—JAMES WILLOUGHBY PHILLIPS, at Clifton Heights, New York.—ROBERT F. FORREST, of Watertown,

Mass.—HENRY C. WILSON, of Omaha, Neb., September 20, aged 36.—PRESTON B. SCOTT, of Louisville, Ky., September 24, aged 68.—WILLIAM MUNN, of New York, September 24, aged 51.—J. R. POWELL, of Windfall, Ind., September 20.—JAMES HART CURRY, of Shrub Oak, N. Y., aged 73.

Leper Settlement in Hawaii.—Lepers who live outside the 2 homes draw from the Government a fixed amount of money as a "clothes ration order" every 6 months, in addition to a weekly allowance in provisions. The Bishop Home and the Baldwin Home draw their supplies through the board as required. Many of the lepers have friends outside who provide incomes for them. There are 716 buildings of all classes, including 2 schoolhouses, 2 Protestant, 2 Catholic, and 2 Mormon churches, a courthouse and a jail.

Americans to be Exhumed.—Arrangements have been made for the free transportation to the United States of the bodies of the soldiers, sailors, and civilians who lost their lives and were buried in the Philippines and in China. A burial corps will take passage on the transport *Hancock*, scheduled to leave San Francisco October 1 for the Philippines. All the bodies recovered are to be given an honorable burial in the United States at places selected by the next of kin. In all cases where not otherwise ordered the interment will be made in the national cemeteries, with preference for the cemetery at the Presidio at San Francisco and the Arlington Cemetery, near Washington. The approximate number of bodies to be exhumed is 1,331.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended September 22, 1900:

SMALLPOX—UNITED STATES.

Yellow Fever in Havana.—In 2 days 31 cases of yellow fever have been reported in Havana, making 100 now under treatment. Private advices from Havana indicate that the outbreak is quite serious and that the fever exists in the best parts of the city and among the Americans who have gone there. It is said at the War Department that no fears are entertained of a serious outbreak among the United States troops, as they are outside of the city and not in infected districts. The present outbreak was not unexpected, as fever usually develops about this time of year, and is even worse during the months of October and November than in the spring. Surgeon-General Sternberg does not think there need be any apprehension concerning the spread of the disease.

Havana had 49 deaths from yellow fever in August. Efforts have been made to deduce from this fact the conclusion that the sanitary effects of American rule do not amount to much after all. The chief sanitary officer of the city asserts that, while the fatalities from the fever have been more numerous this summer than they were in 1898 and 1899, it must be remembered that in the August of 1898 all immigration was stopped by the blockade, and that in 1899 it did not begin until the next month, when the danger of infection was small. Major Gorgas says that the real condition of the city is shown, not by the deaths from a disease that is confined mostly to strangers, but by the general rate of mortality per 1,000 inhabitants. Thus tested, the work of the American authorities is fully vindicated, for, while the rate this August was only 27.60, in the first 8 years of the decade it ranged from the lowest, 31.92 in 1893, to the highest, 100.56, in 1898. Yellow fever will probably maintain something of a foothold in Havana for several years to come. The sanitation of the city has only begun, and, while the influx of strangers remains as large as at present, the considerable percentage of non-immunes will have its inevitable effect on the fever record.

Changes in the Medical Corps of the U. S. Army for the week ended September 22, 1900:

MANSFIELD, ELMER E., acting assistant surgeon, will proceed to Fort Bliss, to accompany Company A, Twenty-fifth Infantry, to the division of the Philippines.

BRUHL, CHARLES E., acting assistant surgeon, is relieved from duty at Cabana Barracks, Cuba, and will proceed to No. 21 Fifth Street, Vedado, Havana, Cuba, reporting to the commanding officer, headquarters Second Artillery, for temporary duty, relieving Acting Assistant Surgeon George R. Plummer.

PLUMMER, GEORGE R., will report to the chief sanitary officer, city of Havana, for sanitary duty.

MUNSON, Captain E. L., assistant surgeon, is, on surgeon's certificate, granted leave for one month.

RICHARDS, J. W., acting assistant surgeon, is granted leave for 20 days from about September 18.

GREAR, W. B., acting assistant surgeon, is granted leave for 20 days from about October 1.

DUNSHIE, JOHN F., acting assistant surgeon, will proceed from Fort Leavenworth to his home in New Orleans, La., and report by letter to the Surgeon-General of the Army for annulment of his contract.

WESTERDAHL, GUS J., hospital steward (reappointed September 14), now at Fort Columbus, will be sent to Manila, P. I., for assignment to duty in the division of the Philippines.

The following-named officers of the medical department are detailed as members of the board of officers appointed July 25 to meet in New York City, October 1, for the examination of lieutenants of the line of the Army with a view to selection for transfer to ordnance department: Major HENRY S. KILBOURNE, surgeon; Captain WM. D. CROSBY, assistant surgeon.

NEWLOVE, GEORGE, acting assistant surgeon, orders of September 11 are revoked, and he will proceed from Fort Leavenworth to Fort Sill for temporary duty during the absence of First Lieutenant Marshall M. Cloud, assistant surgeon.

CHAMBERLAIN, GEORGE E., acting assistant surgeon, will proceed from South Newbury, Vt., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for the Philippine Islands.

NICHOLSON, JOHN L., acting assistant surgeon, will proceed from Dorchester, Mass., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for the Philippine Islands.

Changes in the Medical Corps of the U. S. Navy for the week ended September 22, 1900:

HIBBETT, C. T., surgeon, detached from the Cavite Naval Station and ordered to the "Newark."

NORTON, O. D., surgeon, detached from duty with the marine regiment in China and ordered to the "Monadnock."

BENTON, F. L., assistant surgeon, detached from the naval hospital at Cavite, P. I., and ordered to the "Brooklyn."

HAWKE, J. A., medical director, detached from the New York Navy Yard, October 1, and ordered to the naval hospital, Mare Island, Cal.

BRADLEY, G. P., medical inspector, detached from the naval hospital, Mare Island, Cal., on reporting of relief and ordered home and to await orders.

COSTIGAN, G. D., passed assistant surgeon, detached from the "Newark" and ordered to the "Yorktown." (Orders issued by commander-in-chief of Asiatic Station.)

DAVIS, E., assistant surgeon, detached from the "Yorktown" and ordered to the Cavite Naval Station.

Changes in the U. S. Marine-Hospital Service for the week ended September 20, 1900:

CARTER, H. R., surgeon, is upon expiration of leave of absence directed to proceed to Louisville, Ky., and assume command of service.

WERTENBAKER, C. P., passed assistant surgeon, is directed to rejoin station at New Orleans, La.

GWYN, M. K., assistant surgeon, upon being relieved by Surgeon H. R. Carter, to report to him for duty and assignment to quarters.

McKAY, MALCOLM, hospital steward, is directed to report to medical officer in command at Wilmington, N. C., for duty and assignment to quarters.

PECK, F. H., hospital steward, to proceed immediately to Galveston, Tex., and report to Surgeon Peckham for special temporary duty.

foreign News and Notes.

GREAT BRITAIN.

Plague at Glasgow.—Another death from bubonic plague has been reported in Glasgow, making a total of 7 deaths since the outbreak. Only 40 persons are now under observation.

Insurance for bathers is the newest enterprise in the insurance line in England. Penny-in-the-slot machines will be erected in popular bathing places. Before you enter the water you drop in your copper, and out pops a 24 hours' life insurance policy. Then if you do not return your widow or next of kin is entitled to \$1,000.

A sanatorium for tuberculous individuals has been established at Dundee. A gift of \$10,000 by Ex-Provost Moncur largely met the financial responsibility in regard to the building and an anonymous donation of £500 for 5 years was made for its maintenance. The ground for the building was the gift of the late Earl of Airlie. The site is 800 feet above sea level, and comprises 21 acres of ground. Later Ex-Provost Moncur added £5,000 to his original gift.

No Hydrophobia in England.—According to the *Medical News*, the State Department has received from Lord Pauncefoot, the British Ambassador, a memorandum as to the importation of dogs into Great Britain. By enforcing the strictest regulation in regard to muzzling and the importation of dogs the disease of rabies in dogs and hydrophobia in man has been practically stamped out in England. Under the present ruling of the Board of Agriculture licenses must be obtained for the landing of dogs in Great Britain, and a penalty of £20 and the possible seizure of the dog is enforced when a license is not obtained. Masters of vessels are liable to prosecution if dogs are landed illegally, and cannot accept dogs for shipment to Great Britain unless the license is shown at the port of embarkation. Imported dogs are isolated for from 4 to 6 months and are moved about only upon license from the board. When taken out for exercise they must be properly muzzled and in charge of competent persons.

CONTINENTAL EUROPE.

University of Heidelberg.—Professor Carl Gegenbauer, the distinguished professor of anatomy, has resigned his chair on the ground of his advanced age.

Model of Heart.—A German physician has succeeded in making a model of the human heart, which works as in life, pumping blood through artificial arteries.

An Edict Against Long Skirts.—The local board of health in one of the districts of Vienna has placed placards in all the public gardens and parks, directing the women

who visit these places to hold up their skirts if they trail upon the ground. The notice states that as these enclosures are devoted to the recreation of persons desirous of escaping from the dusty town, the authorities forbid dust to be swept there into heaps by trailing skirts.—[*Medical Record*.]

Destruction of Plague-Infected Rats.—It is well known that rats are important agents in spreading plague when it has once gained entrance to a town. The safest plan of extermination appears to be that proposed by M. J. Danysz, of the Paris Pasteur Institute. It consists in the infection of a given rat population with a bacillus of common occurrence which is fatal to the rat. This plan has already been tried with considerable success at Lille, Hamburg, Copenhagen, and Tunis, as well as in Paris itself, for the extermination of rats quite apart from their connection with the plague.

Is France Infested?—Physicians of the Pasteur Institute have advised the French Government to take certain sanitary measures to prevent the propagation of bubonic plague in case it should drift from England to Paris. Under the title "Is France Infested?" a Marseilles newspaper ventilates rumors that not less than 20 plague deaths occurred in southern seaports of France during the past summer, and that the secret had been carefully guarded by the Government in order not to alarm visitors to Paris. One of the Pasteur Institute scientists says he fully expects the disease to break out simultaneously all over Europe and North and South America next summer.

Petroleum Drinkers.—The Medical Society of Paris has expressed the opinion that it is necessary to adopt some measures against the alarming spread of petroleum drinking. At first it was thought that this habit had sprung up from the increased taxation on alcohol, but an investigation showed that this was not the case; the habit had been prevalent some time previous in the suburban town of Bastille, and had spread with great rapidity. The victim of the petroleum habit does not become brutal, only morose. The opinions differ among the physicians as regards the effects of petroleum drinking on the human system, but they all agree on the harmfulness of this new vice.—[*Diet and Hygienic Gazette*.]

MISCELLANY.

Female Physicians in Asia.—Within the last 20 years the number of American and English female physicians in Asiatic countries has increased from 20 to 220.

Goat's Serum in Leprosy.—It is stated that experiments are being made with goat's serum in the treatment of leprosy at the Pasteur Institute at Hanoi, the capital of Tonkin. Two patients in whom this method of treatment has been employed are said to have been benefited considerably.

Emperor Kwang-Su has Carcinoma.—Dr. Bachmann, of Shanghai, has recently stated that Emperor Kwang-Su suffers from carcinoma of the throat, and is unable to reign. Dr. Sheng Lian Feng and a French physician, Dr. Dethère, have both reached the same conclusion. This seems to be a disease to which rulers are specially prone.

Obituary.—TREVOR AUGUSTUS DAGG, of Worthing, England, September 4, aged 38.—ROBERT WHITWORTH PAYNE, at London Hospital, September 6, aged 29.—ARTHUR WYNNE FOOT, of Dublin, September 1, aged 62.—JOHN PRIESTWICH, of South Africa, August 28.—JOHN BURTON ST. CROIX CROSE, of London, aged 85.—MAX SCHÄFER, of Bremen.—PIERRE LEBRUN, of Brabant.—PROF. FRANZ NICHIL, of Prague, aged 50.—DR. JASKULOW, of Pöhlipfel.—MANUEL ISIDRO OSIO, of Madrid.

The Wounded in China.—The Grand Ducal Government of Baden has decided to grant the use of their bathing establishments, with all their therapeutic appliances, to officers and soldiers of the allied forces wounded in China free of all cost. A committee has been formed, consisting of the most prominent officials and leading citizens, who have begun their work by circulating a notice to this effect to such physicians, chemists, sanatoriums, hotels, and boarding-houses as are likely to receive inquiries.

Leprosy in Lithuania.—The Lithuanian Society for the repression of leprosy, as the report for 1899 shows, received during that year 24,928 and expended 49,787 roubles. The excess of expenditure over income is due chiefly to the erection and equipment of a new leper house with 120 beds, which was opened at Tarwast in October, 1899. In the 4 leper houses at Muhl, Nennal, Wenden, and Tarwast, there were at the beginning of the year 137 patients, as against 143 in the previous year. During the year 24 died, 20 discharged themselves, and 72 new cases were admitted. At the close of the year the total number of patients was 165. The 4 leper houses together provide accommodation for 280 cases.—[*British Medical Journal*.]

Medical Society of Japan.—Eleven years ago, Dr. Senya Saito founded a medical society at Kyao, Japan. That society, of which he is president, now numbers 291 members. The members give disinterested help to the Government and the authorities of the town on medical and hygienic questions. Thus last winter they saved the town from the plague, and 10 years ago they were instrumental in saving innumerable victims after the great earthquake. They meet every month for the discussion of professional questions, and they have a journal which is published monthly. There are in Japan 2 universities and 5 medical schools. There is in addition a kind of practical medical school under the auspices of the Government.

The Treatment of Prisoners by the Boers.—Lord Roberts in his comment on the report of the Court of Inquiry, according to the *Lancet*, states that the officers were fairly well treated, but that the men were badly treated. The treatment of the prisoners belonging to Colonial corps raised in South Africa Lord Roberts considers to have been opposed to the usages of civilized warfare in that they were treated as criminals, and the same remark applies to British subjects resident in the Transvaal who were treated in a like manner because they refused to take the oath of allegiance to the Republic. Lord Roberts also considers that the inhuman treatment of the sick prisoners throws the greatest discredit on the authorities at Pretoria, since they must have known that proper hospital accommodation and equipment had not been provided, that suitable food and medical comforts were not forthcoming, and that the supply of medicines and medical comforts was wholly inadequate. The commander-in-chief's conclusions form a severe indictment of the Republics, but the documents which are included in the dispatches, appear to warrant the conclusions.

Treatment of Apparent Death of the Newborn.—Schultze (*St. Louis Medical Review*, September 8, 1900) says that if the child is reddish-blue and there still exists some tension of the muscles, he defers severing the umbilical cord as long as the heart-beat is perceptible. He removes the mucus from the mouth, and excites the skin-reflexes. If there is not immediate reaction, cut the umbilical cord, plunge quickly and for a very short time into very cold water, and then into warm water. Repeat these immersions until the child cries loudly. If the body of the child has the pallor and flaccidity of a cadaver immediately after death, do not expect to obtain anything by excitation of the reflexes. Cut the cord at once, remove the mucus from the mouth and pharynx, pull out and press down the base of the tongue to elevate the epiglottis and then do artificial respiration, either by Sylvester's method or by swinging the child. Commence with a long expiration. There is no better means of cleaning the aspired mucus from the large and small bronchi. After having changed the position from expiration to inspiration 8 or 10 times the minute, plunge the infant into a warm bath and watch it. You will see the heart-beat become stronger and more frequent, the skin redden, and the muscular tension return. If in a short time you have not succeeded, begin again to swing the child after the bath. The expiratory movement ordinarily causes the first inspiration spontaneously. If, however, the respiration remains superficial, plunge the child into ice water. It will react at once, bend the thighs strongly and cry aloud; the medulla now responds to reflex irritation. Never consider a child, born in a state of asphyxia, as completely resuscitated until it cries continuously and loudly. [G.C.H.]

Society Reports.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fiftieth Annual Meeting, Held at Wilkesbarre, September 18-20, 1900.

FIRST DAY.

THE Society was called to order at 9.30 A.M. by the President, DR. GEO. W. GUTHRIE, of Wilkesbarre. The delegates were welcomed to the city by the Mayor, Hon. F. M. Nichols, and by Dr. H. M. Neale, President of the Luzerne County Medical Society. The forenoon session was devoted to the reports of the various officers and committees of the Society.

At the afternoon session the first paper read was the **Diagnosis and treatment of the early stages of tuberculosis**, by CHARLES REA, of York. An afternoon temperature-rise, attaining the maximum at 5 or 6 P.M. is of great diagnostic value. Next in importance is increased pulse-frequency, associated with a lowered arterial tension. The early diagnosis must be made more from the history and symptoms than from physical signs. Skiagraphy is an aid only to those who are expert in its use. Tuberculin is a dangerous diagnostic agent, as it may change a local condition into a general infection. In the treatment more attention should be paid to bodily resistance of individuals and thus prevent the disease. Abundant nitrogenous diet should be given, and the best air secured. If change of climate is suggested, the facilities of the new place should first be carefully studied. Rea finds pulmonary gymnastics to be of great service, especially when combined with intrapulmonary treatment by nebulization. Ichthyol often answers as well as creasote.

Old-time treatment and result of typhoid fever was the subject of a paper by W. H. HARTZELL, of Allentown. The speaker reviewed the various drugs which at times were considered of great efficacy, as digitalis, aconite, potassium iodid, etc. Bathing is one of the few old-time treatments which have survived. The early treatment he divided into three periods: First, the period of indifferent treatment by drugs from the recognition of the disease to 1860, the mortality being 27%; second, the period of incomplete antipyretic treatment, 1860 to 1866, mortality 16%; third, the period of systematic antipyretic treatment, 1866 to 1875, mortality 8%. In the discussion ESHNER, of Philadelphia, said that the formula of Brand should be used in a general way but not literally in every instance. Each case has its own indications and the temperature of the water, frequency of bathing, etc., should be determined by the intelligence and discretion of the physician, and not by a rigid formula. It is also better to reduce the temperature only 2 to 3 degrees every 3 hours. If the digestive function be good the patient will do well on a semiliquid diet such as junket, soft eggs, rice, etc. KOENIG, of Pittsburg, believes that giving large quantities of water is beneficial and claims that in cases where large quantities of urine are passed the prognosis is good regardless of the symptoms present.

The next paper, **Lecturing not teaching**, was read by T. D. DAVIS, of Pittsburg. He believes that many of the failures before the State Board are due to faulty methods of instruction in the medical schools. The student does not actually learn so much in one year in a medical college as he formerly did under a preceptor. It is impossible for a lecturer to adapt his lecture to the varying capabilities of a first-year class. Hence during the first two years of the medical course the chief method of instruction should be recitations and compulsory quizzes. Later on the lecturer would have a foundation in the common knowledge of all the students on which he could build.

The human temperaments and their application in medicine was the topic treated by J. C. BATESON, of Scranton. The physician should have a knowledge of the various temperaments as well as of physiology, as the two are closely connected. A knowledge of temperaments aids materially in the treatment of many cases.

J. EMMET O'BRIEN, of Scranton, read a paper upon the **Analogies between nervous and electric mechanisms**, illustrating the joints by a series of charts. He believes that nerve force and electricity are identical. If nature produces electricity in the organic cells of certain fish and eels for offensive and defensive purposes, why can she not do this in the cells of human beings? The term "nerve force" is meaningless and has handicapped physiology as much as has the term "vital force." Nerve fibers are insulated as are the wires in a cable. The sympathetic system is an exception, but it does not convey special messages as do other nerves. Summary: Nerve force is electricity; it is produced in the nervous system by chemical processes analogous to those which produce heat in the general tissues; it would advance knowledge of the nervous system and its functions to acknowledge this proposition, at least as a working hypothesis.

The treatment of pneumonia with antipneumonic serum was discussed by EDWIN ROSENTHAL, of Philadelphia. This treatment often brings the crisis in 12 to 24 hours. The serum is given hypodermically, preferably in the affected side of the chest. The temperature, pulse, and respiration are taken as a guide for the size of the dose. From 20 to 40 cc. are given as the initial dose. Double the initial dose is then given every 4 hours until the desired effect is obtained, which is generally in from 24 to 48 hours in cases of primary pneumonia. When the pneumonia is secondary alternate doses of the antipneumonic and anti-streptococcic serums are used. Any indication, as weak heart, etc., should be met by drugs the same as though the serum was not being used. The serum is harmless and may be used to any quantity. The best results follow its early use.

THOMAS C. ELY, of Philadelphia, reported a case of **meningitis complicating pneumonia**. The patient was a boy of 6, the symptoms of meningitis appearing on the twenty-third day of an attack of pneumonia at first croupous, then lobular, in type. Cerebrospinal fever and tubercular meningitis were both excluded. The case ended in recovery.

JUDSON DALAND, of Philadelphia, read the notes of **A case of Raynaud's disease**. At times an excessive quantity of indican appeared in the urine, and acetone was also found. During these periods the patient was improved by treatment which relieved the autointoxication.

The diagnosis of ectopic pregnancy, with notes of a case, was the subject of a paper read by J. M. BALDY, of Philadelphia. The patient ceased menstruating in June. Pelvic pain was felt in July and August and became severe in September. Operation revealed a 3-months' ectopic pregnancy. All the classic signs of this condition, with the exception of one, were present. That one was the presence of vaginal or uterine bleeding. Not a sign of blood or decidua had appeared. The case was reported to show that such cases do exist, i. e., there is no effort made to throw off the decidua membrane. The presence of blood or decidua is therefore not necessary in order to make the diagnosis of ectopic pregnancy.

At the evening session PRESIDENT GUTHRIE delivered the annual address. Following this was a reception by the Luzerne County Medical Society at Hotel Sterling.

The president's address was a review of the various forms of quackery which flourished in olden times and which so delude the people at present. There is no limit to human credulity, especially in matters of health and sickness, and any method of healing that claims to be supernatural in power finds hosts of followers. The speaker, in discussing Dowicim, Christian Science, osteopathy, etc., disclaimed any intention of inveighing against medical sects practising under legitimate conditions. There is no justification for medical sectarianism, and all honest investigators should be united under one banner in the contention against quackery and deception of every kind. The size of a dose of medicine is a little thing upon which to split and retaining a distinctive sectarian title as a trade-mark is not becoming honest, scientific investigators. Legal practitioners should unite in an appeal to the Legislature for the passage of an act defining justly the term "practice of medicine," as attempts to execute the laws now existing would simply give the pretender a little cheap martyrdom which would aid rather than deter him in his business. Medical legislation

has been productive of much good and with a proper definition of the practice of medicine all persons pretending to heal would be obliged to come before the State Board of Examiners and meet the same requirements as are demanded of legal practitioners.

SECOND DAY.

The morning session began with the **Address in surgery**, by WALTER LATHROP, of Hazleton. The subject of this admirable paper was fractures of the spine, particularly of the dorsolumbar region, and their treatment. The speaker stated that of spinal injuries 20% were dislocations, 20% fractures, and 60% fracture-dislocations. In the diagnosis the most important sign is displacement of the spinous processes. Attempts to elicit crepitus are decidedly dangerous. As to treatment, reposition of the fragments suggests itself, and extension, watching the bladder, etc., is often followed as a routine measure by surgeons. Lathrop believes that extension does little if any good and may do a great deal of harm. Loose fragments of bone may be pressed into the cord and thus cause damage in addition to that of the original injury. The use of an air bed and perfect rest is better than extension. Operative measures give relief when pressure is being exerted. Nothing can be more rational than the removal of fragments of bone which are pressing upon the cord, and the number of patients that have been relieved by this procedure justify operation. It should be done within 48 hours after the accident. In thus speaking of operation Lathrop excludes injuries of the cervical region, operative interference in that region not being advisable. Strychnia should be given some hours before the operation, heat applied, the anesthetic given very carefully, and the operation done as rapidly as is consistent. The greatest danger is infection. If the dura is intact it should not be opened unless there be evidence of pressure beneath. Oozing will demand a change of dressing within 24 hours, but after that it should not be done oftener than every 48 hours. The present average of 7% cured should be increased with earlier operations. Lathrop has had 7 cases of undoubted fracture with 3 deaths, 3 greatly benefited, and 1 cured. Four other cases refusing operation have remained paralyzed for periods of over two years each and are at present inmates of the poorhouse.

The second number was a **Symposium on typhoid fever**. In the absence of J. M. ANDERS, of Philadelphia, his paper on **History and statistics** was read by DR. TAYLOR. The predilection of the disease for camps and crowded quarters and its occurrence in every regiment during the Spanish war, regardless of location, was mentioned. The **Etiology** was discussed by CHARLES H. MINER, of Wilkesbarre. A paper on **Diagnosis**, by J. I. JOHNSTON, of Pittsburg, was read by title. H. A. HARE, of Philadelphia, spoke of the **Complications and sequels**. Attention was called to the fact that textbook descriptions are only pen-pictures and each case may have many points of difference. Constipation is probably present in the majority of cases. Many cases have a more sudden onset than the classical type, and curiously enough the convalescence in these cases is often more rapid than in those of slower and seemingly more mild onset. Hare believes that the disease is undergoing a modification in type. There is a constant decrease in frequency and a still greater decrease in mortality. He cannot attribute this entirely to advance in therapy and thinks that the disease is decreasing in virulence or that there is an increase in the resisting power of individuals. ALFRED STENGEL, of Philadelphia, spoke of the **Treatment**. The first indication is to support the system. The bath treatment is undoubtedly the best supportant, but cannot be used in every case because absolutely refused by patient or friends, because it may lead to hysterical manifestations, or cause excessive discomfort by shivering, etc. In 196 cases so treated at the University Hospital he has had 9 deaths. It is irrational to omit hydrotherapy unless the temperature is above 102½°. It is advisable to use it in some form in cases having a low temperature, as its chief value lies in its supportive and roborant powers. Alcohol is a valuable stimulant, but is too often administered and in too large doses. When 6 to 8 ounces in 24 hours does not suffice, larger doses will not do good. It is better, then, to use small doses of strychnin in conjunction. Injections of camphor, 1 grain in 15 m. of olive oil, act as a stimulant and also quiet the

nervous system. The second indication is to avoid complications. Silver nitrate and opium are used to check diarrhea. Diet is of more importance than drugs for this indication. A paper on **Diet**, by JAMES TYSON, of Philadelphia, was read by title.

WILLIAM H. DUDLEY, of Easton, read a paper on **The question of the enforcement of the medical laws of Pennsylvania**. There is a growing disregard of existing medical laws. Dudley made a plea for a more definite interpretation of the law and the providing of means for its enforcement. At present regular physicians would have to prosecute illegal practitioners at their own expense and bear the brunt of public opinion. MCINTIRE, of Easton, stated that the law had two weak points: (1) There is no official registration of legally practising physicians; (2) there is no official body to look after the prosecution of illegal practitioners. The power of conviction in such cases should be taken from juries and vested in judges alone.

A resolution was adopted providing for a committee of three to enforce compliance with the medical laws of the State and appropriating \$1,000 from the treasury of the society for that purpose. The members of the committee are WEAVER, of Wilkesbarre; MCCORMICK, of Williamsport; and HAMAKER, of Meadville.

T. M. T. McKENNA, of Pittsburg, reported some **medico-legal cases**. These were classified under three heads: (1) Cases of severe primary injury; (2) apparently mild injuries followed by important symptoms; (3) mild injuries with assumed symptoms. Under the second class were considered cases of traumatic neurosis. Many of these are induced by psychical rather than by physical trauma, the former having the same effect as in cases without physical injury. In the discussion DALAND spoke of traumatic hysteria and said that some of these cases do not recover after receiving heavy damages. DAVIS spoke of medical experts in these cases and said that many physicians were afraid to give testimony because it was claimed that they brought discredit upon the profession. This sentiment should be changed. Lawyers do not agree, judges' decisions are reversed, and there is no discredit if doctors do not testify to the same things.

Four phthisical remedies which have proved most valuable in my experience was the subject of a paper by T. J. MAYS, of Philadelphia. These remedies were stated to be rest, food, strychnin, and silver nitrate. The latter is injected hypodermically in the cervical region. Of the cases treated by the latter method 11 incipient cases are well; of 18 advanced cases 6 have been much improved; of 15 far advanced cases 12 are dead and 3 yet living. In the discussion J. SOLIS COHEN said that the use of silver-nitrate injections was on the same principle as the stimulation of the pneumogastric nerve by the hot iron, etc. Strychnin is very valuable, especially in small doses often repeated— $\frac{1}{100}$ grain every hour. Red meats are the best food. Rest in the open air is always to be used. In the Home for Consumptives at Chestnut Hill the patients are kept in the open air even during the winter.

The afternoon session opened with the **Address in Obstetrics** by CHAS. P. NOBLE, of Philadelphia. Puerperal infection was the first topic treated. The great advances made in this line in hospitals made the question of morbidity at present of greater importance than that of mortality. That antiseptic and aseptic methods have not thus permeated private practice can be proved by statistics, and better work should be done by private practitioners. As the normal vagina has been proved to be sterile, antepartum douches are not to be employed. Efficient prophylaxis, therefore, consists in the thorough disinfection of (1) the external genitals; (2) the hands of the physician; (3) the hands of the nurse; (4) all instruments employed. There is a connection between the frequency of internal examinations and puerperal sepsis. The physician is culpable who neglects to study carefully each maternal case before labor. Prophylaxis and conservatism in gynecology were then discussed. The great majority of pelvic inflammations are due to puerperal infection or to gonorrhea. People should be educated in the importance of the latter. It has been learned that the removal of healthy ovaries will not cure diseases of the nervous system, and the substitution of myomectomy for hysterectomy in single women under 35 is another advance in conservatism.

G. G. DAVIS, of Philadelphia, read a paper on **Applied**

anatomy; its value and place in the medical curriculum. This differs from either regional or surgical anatomy. Students who leave school after studying anatomy as it is usually taught and practitioners cannot meet on a common ground in examination. Hence the question of the practical examination of candidates by State boards arises. The outlines of a course in applied anatomy were then given. This included the study of surface markings, the tracing of vessels and nerves with crayon, the study of the deformities caused by fractures and dislocations, and the changes in the joints, etc. In the discussion, HENRY BEATES, JR., stated that anatomy was one of the branches he had recently called attention to when speaking of the necessity of systematizing the curriculum of medical colleges. All branches should be put upon a common basis in all medical schools. The question of interstate reciprocity could then be based upon the pedagogical principles of the medical schools and would settle itself.

Appendicitis and its treatment was discussed by MORDECAI PRICE, of Philadelphia. Attention was called to the fact that operative mortality was increased by cases held too long by medical treatment. Pus cannot be removed by medicine, and of his 189 cases pus was found in all but 2. Thorough irrigation and gauze drainage are the two great essentials in operative treatment. After-treatment, by allowing the wound to close too soon, may easily be responsible for death. In the discussion G. G. DAVIS stated his belief that physicians as a whole are almost too eager for operation, calling in the surgeon when the diagnosis is not at all certain. BALDY does not believe in a lengthy search for the appendix without breaking up adhesions. It is said that normal appendices are being removed. He has seen the removal of what appeared to be normal organs. Yet the patients were operated upon because of symptoms and the symptoms disappeared after the removal of the appendix.

PRESIDENT GUTHRIE exhibited the youngest patient upon whom he has operated for appendicitis. This was a boy 2 years and 9 months of age, operated on in July with a perfect recovery.

O. C. GAUB, of Pittsburg, read a paper on **The surgery of the gallbladder.** Cholecystitis is probably the cause instead of the effect of gallstones. The majority of the attacks of biliary colic are not effective in moving the stone, hence early operation is advisable. The disease is more treacherous and obstinate than appendicitis and the patient should be watched carefully. The merits of the operations of cholecystectomy, cholecystotomy, and cholecystendesis were discussed. Gaub fails to see benefit from suturing the gallbladder to the abdominal wall. Cholecystotomy leaves the diseased area. He believes cholecystectomy to be the operation of choice for the following reasons: (1) the diseased organ is removed and there can be no sequel; (2) convalescence is shortened; (3) the mortality in suitable cases is no greater than that from the other operations. Three cases of cholecystectomy at the Mercy Hospital were reported. A good recovery followed in each case.

E. O. KANE, of Kane, described **A removable buried suture for abdominal incisions.** Silver wire is drawn through each layer of tissue separately by means of a silk thread in a needle. The chief feature is the removal of a section of skin where the sutures are introduced in order to prevent infection. The sutures are fastened by buttons. They may be removed together or separately.

Tuberculosis of the bladder was the subject chosen by F. P. BALL, of Lock Haven. Extensive notes of a case were read. Twenty years ago Dr. Agnew diagnosed it as hypertrophy of the prostate. Two years ago another expert made the same diagnosis. Tubercle-bacilli were afterward found in the urine. An extensive operation was done, death following. The case was cited to show the difficulty in diagnosis and the necessity of operating before a large area was involved. Symptoms include pain, greater when the bladder is full, pain at the middle of the penis, hematuria, frequent micturition, and a contracted bladder. In the discussion NOBLE stated that the microscope almost invariably failed to show tubercle-bacilli in the urine. He has cured a number of cases in women by the application of fused nitrate of silver. In one case a vesicovaginal fistula was made to allow of irrigation and application, the fistula being closed afterward. BALDY said that few cases of undoubted tuberculosis are cured. When the process is localized the part should

be resected. Those cases cured by medicine are not tuberculosis.

J. C. DUNN, of Pittsburg, spoke of the efficacy of **silver nitrate in dermatology.** He has used this drug in all varieties of eczema, in strengths varying from 3 grains to the ounce up to the solid stick, with excellent results. It also acts well in some cases of psoriasis. In an extensive case he applies the silver nitrate and either salicylic acid or chrysarobin to opposite sides of the body for the first applications. Whichever gives the best results is then chosen and continued. A strong application of silver nitrate is very efficient in relieving the pain of herpes zoster.

Primary tubercular adenitis—surgical treatment, was the title of a paper read by L. J. HAMMOND, of Philadelphia. The location, etiology, and pathology were considered. The surgical treatment was divided into three stages—glands, abscesses, and sinuses, details being given for each of these conditions.

W. M. BEACH, of Pittsburg, read a paper on **Constipation or obstipation and its surgical treatment.** He reported 26 cases in which permanent relief was secured by the removal of the rectal valves. The majority of cases of obstipation are caused by the hypertrophy of these valves. The operation of valvotomy as he performs it was described, the instruments used being exhibited. General anesthesia is seldom necessary. Cocain, followed by suprarenal extract, is applied. The chief dangers are hemorrhage and peritonitis. To guard against the former a styptic tampon is applied after the operation, considerable pressure being used. Beach thinks the operation is practically limited to the proctologist. This procedure not only cures obstipation, but is the key to the relief of many cases of seminal emissions, autoinfection, etc.

Surgical diagnosis by the Röntgen method was the subject of a paper by CHARLES L. LEONARD, of Philadelphia. To use this means of diagnosis the observer needs a broad foundation of surgical anatomy and pathology, as well as a knowledge of the electrical and mechanical technic. This method now furnishes absolute diagnosis in many cases where formerly exploratory operation was the only means of determining the condition present. Besides locating fractures it gives valuable indications for treatment by showing the pathologic conditions to be overcome. Thus in some cases operation is indicated for simple fracture. The greatest advance in diagnosis has been in differentiating calculus nephritis from those conditions simulating it. Of 90 such cases examined by Leonard, only 20 were shown to be real cases of calculus. Symptoms in 8 of the other cases were so urgent, however, as to demand operation. The negative diagnosis by the x-ray was confirmed in each instance. The method is valuable then because of the absolute accuracy of its negative as well as positive diagnosis. The smallest calculus found by this method weighed $\frac{1}{16}$ of a grain.

THIRD DAY.

The morning session began with the **Address in hygiene** by JOSEPH T. ROTHROCK, of West Chester. The two topics considered were water-supply and the treatment of incipient tuberculosis. Regarding the first topic two facts were insisted upon: 1. The most important use of water is to sustain human life. 2. Water supply should never be allowed to pass into the control of citizens who have other uses for it. Filthy water filtered will always be a poor substitute for pure water. Three methods for obtaining pure water suggest themselves: (1) State ownership of the heads of water-supply; (2) the use of water from the clouds; (3) the use of distilled water. The first method is the best and is that held in view by the State Forestry Commission. The State is now in possession of 123,000 acres of forest land and there are 2,000,000 acres in the State which could not be devoted to a better purpose. In connection with this it was stated that the State must at some time care for its consumptives and these public forests will solve that question. The Forestry and Sanitary Commissions might well join hands for this purpose. There are many people suffering from tuberculosis who can not afford to go to Colorado or Florida. With the State in possession of large tracts of forest not less than 1,200 feet above the sea level, it could say to these sufferers, "There is healing in our woods." Buildings to afford shelter from storms, but allowing free access of air could be erected by the State and rented to consumptives, they living according

to their means. The rental would soon repay the cost of erection.

DR. H. BERGEY, of Philadelphia, in a paper entitled **Recent advances in the bacterial purification of sewage**, reviewed the various methods employed for rendering this material innocuous. President GUTHRIE spoke of the healthfulness of Atlantic City being secured by thus disposing of its sewage and by using artesian well water.

Humanology, or higher physiology, was the subject of a paper by E. N. RITTER, of Williamsport. She stated that the greatest danger came, not from degenerates, but from parents of average type who were ignorant of the care of unborn and born children. The active power or tendency of the pregnant woman becomes the dominant power in the child. Children should be instructed regarding maternity. They can be educated sexually without injuring their morals and this will accomplish much more for the human race than will legislation. In the discussion of this paper BATESON agreed with the author. He spoke of an effort being made in Ohio to make compulsory the examination, by physicians, of those intending marriage and said that the question should be agitated. The profession should give more attention to the morals of the people from a medical standpoint. MASSEY said that the medical profession had been slow in causing women to know the danger in marrying unexamined men. Parents should go slow in teaching young pubescents sexual matters, but both parties in a contemplated marriage should be educated. MYERS would castrate every man who is a criminal. GIBBONS said that every child should be trained by women alone up to the age of 12 or 15 years. He would not unsex criminals. BISHOP said that it was a mistake to talk of controlling human beings by breeding, etc., as was done with brutes. Man has a higher purpose and cannot be limited in this way. It is debasing to talk of examining persons contemplating marriage.

Sanitary milk for children was the topic of B. H. DETWILER, of Williamsport. He spoke of the effect that gestation in cows has upon their milk. He formerly recommended the milk of one cow for an infant, but now recommends herd milk. The effect upon the milk by the operation of spaying was discussed. Two cows in the herd at Danville have been eayed and careful experiments with the milk will be conducted and reported. STENGEL spoke of the good work done among the milk-producers by a committee of the Pediatric Society of Philadelphia. He believes that the State cannot regulate the milk-supply and that societies of medical men can do much toward the securing of sanitary milk for children by stimulating the producers. He urges the appointment of committees by local societies for that purpose.

G. BETTON MASSEY, of Philadelphia, made a further report on the cataphoric treatment of cancer. Of the 37 cases treated since 1893 10 have been cured, 3 are doubtful, and 24 were failures. Of this number 7 were operable and 30 inoperable.

JOHN M. BATES, of Downingtown, detailed his treatment of the nausea and vomiting of pregnancy. A careful trial of remedies has convinced him that this condition cannot be relieved by the use of drugs; constant feeding has given the best results. A glass of milk, a cracker, or orange is kept constantly on the table near the bed during the night as well as the day, the patient making use of them whenever hungry. A breakfast of coffee, milk, chops, steak, etc., is given while the patient is in bed in the morning and 3 or 4 full meals during the day. Fasting during the night is conducive to morning sickness.

Paroxysmal delirium—a short study in auto-intoxication, was the subject discussed by W. C. HOLLOPETER, of Philadelphia. Notes were read of 3 cases of delirium in children, the symptoms disappearing with the use of calomel and irrigation of the bowels. DALAND spoke of the lack of any really sure signs at present that will demonstrate auto-intoxication to the clinician. An exact method of detecting indican and other matters in the urine is needed. PEARCE finds the wet pack of value in the treatment.

Nephritis as a complication in gynecological disease was spoken of by G. E. SHOEMAKER, of Philadelphia. The various conditions giving rise to nephritis were mentioned. An important one is cystitis resulting from cystocele and sacculatation of the bladder. An acute cystitis following a pelvic operation may extend to the kidney. Chronic pel-

vic suppuration is a fruitful source of kidney disease. An acute renal irritation as a cause of high post-operative temperature must be borne in mind.

J. H. MUSSER, of Philadelphia, read a paper upon **Myocarditis**. The various forms of myocarditis were spoken of, especial attention being paid to the fibrous variety or coronary artery disease. An important sign of this condition is the sallow pallor of the countenance, which is not seen in any other condition. Another is the prematurely old appearance of the patient. A murmur is not heard until late in the disease.

REED BURNS, of Scranton, reported three cases bearing on the question of **ovarian hydrocele**. They were not strictly ovarian hydrocele, but showed how the ovary can be shut in by a local plastic peritonitis. The ovarian fossa was unusually deep in each case.

Do we resort too frequently to surgical operations? was the subject under which R. H. GIBBONS, of Scranton, showed what a great boon surgery has become, and also justified the surgeon.

The afternoon session opened with the **Address in ophthalmology**, by CHARLES MCINTIRE, of Easton. The history of a people can be learned better from a study of their words than from their literature. So in ophthalmology. The speaker showed this from words beginning with a. First was the alpha of euphony, as in a-maurosis. Following this came the alpha of negation and a-metropia was coined. This was only possible by research and inquiry. Later came a-thenopia, denoting failure to perform function rather than disease of the organ.

E. B. HECKEL, of Pittsburg, spoke of **The electro-magnet in eye surgery**. The speaker described a magnet of his own pattern which has given excellent results. The main features are the tapering point of the core and the fact that the core is of soft steel. This causes the magnet to gain strength slowly and thus cause less jerk when it acts. Heckel thinks it is never justifiable to make a new opening in the eyeball while the original one is patent.

C. A. VEASEY, of Philadelphia, made **A plea for the earlier recognition and treatment of squint in children by the family physician**. Between 4 and 5 years is the usual age for squint to develop and treatment should be instituted. The treatment was detailed. Operation, when necessary, should be after the sixth year.

P. J. KRESS, of Allentown, read a paper on **The relation of the oculist and optician to the profession and the public**. The paper emphasized the need of medical training in those who prescribe glasses.

CHAS. A. MINER, of Wilkesbarre, exhibited patients showing **Leukemia and pseudoleukemia**. The former was a boy of 12, who had had malaria. The spleen rested on the pubic bone and by pressure on the bladder caused incontinence of urine.

Surgical intervention in purulent discharge of the ear was discussed by JOSEPH E. WILLETS, of Pittsburg.

F. SAVARY PEARCE, of Philadelphia, read a paper on the **Climatology of neurasthenia**. Damp, low localities are to be avoided. No case does well at an altitude of over 2,000 feet. Localities where heavy storms occur are not beneficial. Suitable places are the inland regions of New Brunswick and Nova Scotia and the regions of the Great Lakes.

A. A. ESHNER, of Philadelphia, reported two cases of **Paralysis agitans without tremor**. The tremor was so slight as to be of no diagnostic importance.

L. J. LAUTENBACH, of Philadelphia, read a paper on the **Best method of removing postnasal adenoids**. This is by means of the finger alone, or reinforced by a metal fingernail in obstinate cases. Cocain is used, and the operation lasts only 10 to 25 seconds. Recurrence is very rare.

FRANCIS R. PACKARD, of Philadelphia, gave a review of the literature on **Living animal organisms in the ear**. He has found two cases of maggots in nonsuppurating ears. Treatment was detailed, carbolic acid in warm water being considered the best solution.

Typhoid, its etiology, course, treatment, and pathology, concisely considered, was the title of a paper read by JAMES FULTON, of New London.

CHARLES H. FRAZIER, of Philadelphia, read a paper on the **Treatment of cicatricial esophageal stricture**,

with particular reference to the König method. Notes of a case were given by Frazier. No instrument could be passed through the stricture. A set of silver balls were secured, and the smallest, anchored to the patient's collar by a thread, was swallowed by him. It did not pass the stricture for 24 hours. A larger size was then used. Finally a bougie was passed and the caliber is now nearly full size. This procedure is a safe one and may save an operation, as in the case reported. This closed the scientific program of the meeting. The registration of delegates reached 304. A gratifying feature of the meeting was the able and intelligent report of the sessions by the local newspapers.

The officers elected for the ensuing year are President, T. D. Davis, of Pittsburg; vice presidents, first, W. B. Ulrich, Chester; second, L. H. Taylor, Wilkesbarre; third, A. A. Eshner, Philadelphia; fourth, M. L. Herr, Lancaster; secretary, C. L. Stevens, Athens; assistant secretary, W. L. Pyle, Philadelphia; treasurer, G. B. Dunmire, Philadelphia.

The next meeting of the society will be held in Philadelphia, beginning the third Tuesday of September, 1901.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Thirteenth Annual Meeting, Held in Louisville, Kentucky, September 18, 19 and 20, 1900.

[Specially reported for the PHILADELPHIA MEDICAL JOURNAL.]

DR. A. GOLDSPOHN, of Chicago, read a paper in which he pointed out the erroneous objections to **bilateral inguinal celiotomy** and shortening of the round ligaments via the dilated internal inguinal ring, and alluded to its superior ultimate results in simple and complicated aseptic retroversions of the uterus. For a description of the technic the writer referred to a previous article by him on this subject.

Dr. D. TOD GILLIAN, of Columbus, Ohio, read a paper on **Round ligament ventrosuspension of the uterus**, and described the steps of the operation he performed as follows: 1. A median abdominal incision three or four inches in length, and at the usual site between the umbilicus and pubis. 2. The adhesions are broken up and the fundus brought forward, after which the patient is placed in the Trendelenburg position. 3. Seize the round ligament on one side and bring it to the opening. This may be done either by the fingers or by the aid of forceps. Carry a thread under the ligament at a distance of about one and a half inches from the uterus. The free ends of the thread are brought out of the abdomen and secured by clamp forceps. 5. The other round ligament is secured in the same way. 6. Expose the rectus muscle near the lower end of the incision by retracting its sheath and by rolling it out of its sheath on the tips of two fingers applied to the peritoneal surface under it. 7. Select a point one inch external to the margin of the incision and something over an inch above the pubis through which the perforating forceps specially devised for this purpose is thrust into the peritoneal cavity. The two fingers already in the cavity guard the instrument in its passage and place the thread which surrounds the ligament within its jaws. 8. The perforating forceps is now withdrawn, after removing the clamp forceps from the thread, and both thread and ligament are brought up through the perforated wound in the abdomen. 9. While the ligament is held taut, fasten it into the wound by a to-and-fro catgut suture passed deeply through the ligament and including the tissues on either side. 10. Treat the opposite side in the same manner, and close the median abdominal incision. Rigid observance of all the rules of aseptic surgery is essential to prevent supuration, and only a small loop of the ligament should be drawn up through the wound.

DR. W. E. B. DAVIS, of Birmingham, Alabama, reported an interesting case of **composite teratoma of the ovary**. Pathologic and microscopic examinations were made and a report appended to the history of the case.

DR. CHARLES G. CUNSTON, of Boston, read a paper on the **Treatment of chronic cystitis in the female by curetment of the bladder, and instillations of corrosive sublimate**. See Abstracts of *Medical Record*, this issue.

DR. A. VANDER VEER, of Albany, N. Y., read a paper entitled **Some points regarding the surgery of the gallbladder**. Four interesting and instructive cases were reported, and the following summary made: 1. An early diagnosis of cases. (2) In suppuration of the gallbladder with adhesions, a most thorough examination should be made from within by digital exploration, and use of the probe for any possible deep-seated calculi. 3. In prolonged operations upon the common duct or hepatic ducts, where adhesions are present, and it is difficult to close the incision, after removal of the calculus, drainage through the peritoneal pouch by means of the lumbar stab is advisable. 4. When the patient is suffering seriously from cholemia, with marked ecchymotic spots over the body, intense itching, and the blood is examined and found in a septic condition, an operation is not to be encouraged. It is too late, in the vast majority of cases, for the patients to recover. 5. General practitioners as well as surgeons should place more earnestly before the patient and friends the dangers of repeated attacks of gallstone irritation resulting in cancer of the ducts, stomach, or liver.

DR. JAMES F. BALDWIN, of Columbus, O., followed with a paper entitled **Diagnosis of ectopic gestation before rupture, based on 11 cases**. The paper consisted of a brief report of 6 cases of tubal pregnancy which, added to 5 similar cases previously reported by the author, made 11 in all, in which he made a diagnosis of tubal pregnancy and had operated before the occurrence of rupture, his experience having been in direct contradiction to the dictum of Lawson Tait that such an early diagnosis was not possible.

The surgical treatment of uterine displacements was the title of a paper by DR. CHARLES A. L. REED, of Cincinnati, O., in which attention was directed to a couple of modifications of technic in the management of a class of cases that is happily becoming less and less perplexing. In a majority of all cases of retrodisplacements that demand operation at all, the author believes that the intraperitoneal shortening of the round ligaments is the operation of choice. It has been his practice during a number of years to effect this by making a letter of S fold in the ligaments and stretching them thus folded to the parietal peritoneum along the line of Poupart's ligament. This method has yielded him better results than any which he has previously tried. He has, however, become convinced that the parietal fixation of the folded ligament is not necessary for the purpose of holding the uterus in its normal position, and that the technic devised by Mann is all that is required to accomplish this object. His application of this technic differs a little from that originally adopted by Mann, the modifications being those of convenience rather than of necessity.

DR. L. H. LADLEY, of St. Louis, Mo., read a short paper on **Fibroma of the ovary, and exhibited specimens**. He also reported an interesting case of **hernia or diverticulum of the chorion**.

DR. EDWARD J. ILL, of Newark, N. J., read a paper on **Diffuse nonmalignant papilloma of the vulva**, and showed a specimen which he had removed from a patient, 68 years of age. The growth had been over three years' standing. The inner surfaces of the vulva were thickened, at some places appearing horn-like, white and smooth; at other places there were heavy papillae which rose considerably above the surrounding tissue and were from 3 mm. to 15 mm. in diameter at their base. The disease extended from the beginning of the vulva above down to the posterior commissure. It covered the whole vestibule except the tissue immediately surrounding the external meatus of the urethra, and was well defined, but stopped at the vaginal mucous membrane. The vulva as a whole stood out far beyond its normal elevation. The whole vulva was excised. The structure of the tumor corresponds with that usually found in papillomata of the skin. A second case was referred to by the author. These two cases comprise all the experience he has had in this particular.

DR. RUFUS B. HALL, of Cincinnati, delivered his address as president. He selected for his subject **The education of the laity upon sexual matters; when shall they be taught and to what extent?** The family physician should be the educator of the people in sexual matters, and when he gets the endorsement, and is sustained in his position by the specialist, his influence will be greatly strengthened and widened. He advises that during the last year in

high school, in every school in the land, a textbook be used embracing embryology, hygiene, anatomy, and physiology, including sexual physiology, and that these subjects be taught to every student, both male and female. A female teacher should instruct the girls, and a male teacher the boys.

DR. JOSEPH PRICE, of Philadelphia, contributed a paper on **Private hospitals and their management.** These institutions offer advantages that are not given by the schools or political hospitals. The political hospital is not the only corrupt institution; a few of the well-endowed general hospitals, managed and handed down in families to the third, fourth, and even the fifth generations, are the most dangerous institutions in the profession. No one has ever made money and accumulated wealth out of a private sanitarium to his knowledge. He may do so out of the fees, but never out of the board, care and nursing of patients. The board of patients rarely pays 5% on the money invested. Private hospitals give the operator the best opportunity for doing good work. In well-managed private institutions the patient has one or more attendants with well-regulated relays. In public institutions the speaker rarely finds a nurse in a large ward, the only attendants about the patient being a convalescent patient, or an old pelican of an attendant. Fresh beds, and the numerous little attentions from young, intelligent nurses favor comfort and confidence.

DR. JAMES F. W. ROSS, of Toronto, read a paper on **Post-rectal or presacral growths.** He reported four cases of postrectal tumors, and discussed benign and malignant growths in this region; also their etiology, symptomatology, diagnosis, prognosis, and treatment.

The ligature and the value of dry sterilized catgut. A paper on this subject was read by DR. J. HENRY CARSTENS, of Detroit, Michigan. The author described a modification of the Boeckman method of preparing catgut, and emphasized the points that all buried sutures ought to be absorbable and absolutely sterile. Chemicalized sutures are no more sterile than plain sutures. A chemicalized suture is harder and remains longer in the tissues. The latter is a disadvantage. If, in a special case, it is desirable that a suture should remain longer, dry sterilized kangaroo-tendon should be used.

DR. FRANK F. SIMPSON, of Pittsburg, read a paper in which he pointed out some of the contraindications to the intraperitoneal use of normal salt solution after abdominal section.

DR. JOHN B. DEEVER, of Philadelphia, read a paper on **Simple methods in pelvic surgery.** Simplicity is the *sine qua non* of good surgery. It means safety, surety, confidence, neatness, and a great saving of time, which is an essential factor in the success of many operations. The abdominal route is by far the more rational and, therefore, the best method of operating on the pelvic organs in the majority of cases, and offers several advantages that render it preferable to the vaginal. It is simpler of performance. It is safer, as the surgeon can avoid distributing infection where infected areas are present. It reduces the danger of general peritonitis by the use of gauze packing. It renders injuries to the bowel, ureters, important bloodvessels, etc., less likely. It minimizes the danger of hemorrhage. It aids, generally, by the facility offered for inspection. Through the abdominal incision the surgeon is able to open the belly to the proximal side of the infected area, when, by the proper disposition of sterile gauze sheets, practically all risk of peritoneal contamination is done away with. It enables the surgeon to operate with a very few instruments. Radical operations per vagina are, with few exceptions, to be discountenanced, for several good and sound reasons. First, the limited area for manipulation. Second, the impossibility of inspection without destruction and removal of the uterus, which should not be removed except for good and sufficient disease of that organ itself. Third, the marked increased liability to hemorrhage, both primary and secondary. Fourth, increased danger of injuring ureters, bowel, bladder, and large bloodvessels. Fifth, danger of doing incomplete surgery. Sixth, inability to repair satisfactorily injuries to bowel, bladder, etc. Seventh, inability to deal safely with an inflammatory mass which involves the vermiform appendix.

DR. E. F. FISH, of Milwaukee, read a paper on **The treatment of fibroids in the nonpregnant uterus.** The author's conclusions are that myomectomy is the operation

of choice, first, where the tumor is pedunculated. Second, when single, whether subserous, interstitial, or subcutaneous, and can be enucleated without loss of uterine tissue, and the tumor cavity closed and covered with peritoneum. Third, when the desire for an heir outweighs all other considerations. Hysterectomy is indicated: 1. When the tumor involves so much of the uterus that a cavity too large to be properly closed and covered with peritoneum would follow its removal. 2. When several tumors exist, especially nodules. 3. When the adnexae are diseased to such an extent that they must be sacrificed. 4. When the disease ceases to be local. 5. When hemorrhage, pressure, or pain is a persistent symptom. 6. Whenever malignancy is suspected, or the tumor is of rapid growth. 7. After the change of life. Palliative treatment is indicated when the patient is much reduced from loss of blood, as a prelude to rational cure, when the existence of chronic nephritis, diabetes, tuberculosis, or other constitutional disease forbids rational cure; and when the patient is past 40 years of age, the tumor small, the main annoyance hemorrhage, and she is desirous of awaiting the effect of the menopause.

Acute Senile Endometritis.—DR. L. H. DUNNING, of Indianapolis, Indiana, read a paper with this title, it being the second written by him on this subject, and in which he reaffirms his belief that it is a distinct lesion that has not heretofore been adequately described. Since his previous paper he has encountered 3 more cases, 2 of which were attended by sanguineo-purulent discharges from the uterus, and 1 in which there was a large pelvic abscess. The inflammation tends to spread beyond the endometrium into the Fallopian tubes, ovaries, and pelvic peritoneum, resulting in such suffering and ill-health, and not infrequently leading to so serious involvement of these structures as to demand operative procedures, such as extirpation of the uterus and appendages, or vaginal incision and drainage of a pelvic abscess. The chief cause of the lesion is infection. It is not definitely self-limited, but tends to become chronic and to lead to marked degenerative changes within the uterus. The treatment recommended is, in cases where the appendages are not involved, dilation, curetage, the application of a mild caustic and prolonged drainage. When the uterine appendages are involved in the inflammatory process, extirpation of the uterus and appendages is advocated.

Tuboovarian Abscess and How to Deal with It.

—A paper on this subject was read by DR. EDWIN RICKETTS, of Cincinnati, Ohio. Tuboovarian abscess is frequently caused by the proximity of the ovary to an infected Fallopian tube. The disease may be complicated by normal or ectopic pregnancy, intestinal, vaginal, or vesical fistulae, and by appendicitis. In the dormant stage the author operates by the abdominal route; in the acute stage he explores by the abdominal route, and then decides between completing the operation in one or two sittings. Following abortion or delivery at full term, vaginal drainage, in his opinion, often puts the patient in better shape for an abdominal section later on.

The following officers were elected for the ensuing year: President, Dr. W. E. B. Davis, Birmingham, Ala.; first vice-president, Dr. Edwin Walker, Evansville, Ind.; second vice-president, Dr. A. Goldspon, Chicago, Ill.; secretary, Dr. William Warren Potter, Buffalo, N. Y., reelected; treasurer, Dr. N. O. Werder, Pittsburg, Pa., reelected. Cleveland, O., was selected as the place for holding the next annual meeting; time, second Tuesday in September, 1901.

University of Athens.—DR. SAVAS, a Greek Army physician, has been appointed professor in the newly-founded department of hygiene and bacteriology in the University of Athens.

The Congress of German Naturalists and Medical Men held its seventy-second annual meeting in Aix-la-Chapelle, last week. Among the papers read were "Development of Scientific Medicine," Professor J. H. Van Hoff of Berlin; "The Neuron in Anatomy and Physiology," Professor Verworn of Jena; "The Neuron Doctrine from the Pathologic and Clinical Standpoint," Dr. Nissl of Heidelberg; "On the Development of Biology," Professor Hertwig of Berlin; "On the Development of Pathology," Professor Chiari of Prague.

1, 2, 3, 4, 7, 8, 10.—The articles refer to conditions pertaining to the medical service of the British Army. [J.M.S.]

9.—Stephenson reports on the use of the **bicycle** as a means of conveying the field department of the **medical service of the army**. He has had an ambulance made by fastening 2 bicycles together so that a stretcher may be placed between them. This device would seem to be a very useful one for getting the wounded off the field and back to the first stationary hospital. [G.B.W.]

11.—Dent does not believe in the so-called hydraulic theory as explaining the explosive action of the **small-caliber bullets** at short range. The great destruction of tissue which sometimes follows in the track of these bullets is due rather to a radiation of the missile's energy outwards in lines from the long axis of the bullet track. His experience in the Boer war also shows that far better results may be obtained in perforating wounds of the abdomen by conservative surgery, than by opening the abdomen and endeavoring to stitch up the intestinal perforations. He says that the South African climate had a great deal to do with the rapid healing of the wounds. [G.B.W.]

12.—One of the first duties of the medical officer of a ship visiting a given port is to make inquiries from the port authorities as to the prevalence of **infectious disease**, its

extent, and the district affected. If necessary, the proper authorities **aboard ship** should be informed so the men may be warned from visiting a particular district or so the leave may be restricted. The medical officer will also have to pay attention to the people who are allowed on board the ship. If infectious disease exists ashore particular attention must be paid to all minor ailments that may occur among the men so as to detect the first indication of the appearance of the disease among the crew. The first suspicious symptom should determine the isolation and careful watching of the patient. In addition, the immediate neighbors of the suspected man, both at mess and at night, should be watched. Colborne then details the methods of isolating a patient and his attendant on board ship. During the presence of infectious disease all the men should be warned to report every slight ailment so that the early isolation of every case may check the spread of the disease. Should a case of smallpox occur, every man should be vaccinated. [J.M.S.]

13.—The conditions to be kept in mind in the **sanitation of all camps** are: 1. The protection of the troops from the weather and the climate. 2. Feeding them and preventing the occurrence of disease communicated by food. 3. The disposal of excreta and refuse. 4. The prevention of local and endemic disease. 5. The prevention of the spread of communicable disease. According to James the possibility of carrying out sanitation properly must depend upon: (1) the choice of the site of the camp; (2) whether the camp is a standing or temporary one; (3) whether the supplies can be obtained locally or whether they have to be transported; and (4) upon the climate. The primary essentials for properly carrying out sanitary measures in camp are: (1) Discipline and intelligence among the occupants; and (2) an efficient and well-trained sanitary staff. [J.M.S.]

14.—McBride, in speaking of the indications for **intranasal treatment in disease of the ear**, contends that the aurist is now in a position to separate 2 classes of cases, viz., (a) the so-called sclerotic; (b) the catarrhal. In the former it is questionable whether operating on the nose can ever be of benefit, and it may do harm. In the latter it is better to operate on a gross nasal lesion which is causing nasal symptoms, and upon a nasopharyngeal condition if it be present, e. g. adenoids, for these may involve the ear without causing other local symptoms. At the same time he deprecates the operative removal of small deviations and spurs which cause no symptoms appreciable to the patient. Baber believes in operating on cases in which inflation, either by Politzer's method or by catheterization, improves the hearing. Grant says that there is a causal association between nasal obstruction and some forms of disease of the middle ear, especially the moist catarrh; but not the typical sclerotic catarrh. In some cases of nerve deafness good results may follow the improvement in nerve tone produced by the removal of nasal obstruction. [G.B.W.]

15.—In the section of Laryngology and Otology of the British Medical Association, Williams opened a discussion on the **pathology and treatment of toxic paralysis of the larynx**. There are 2 distinct possible methods by which laryngeal paralysis may arise: (1) From the direct application of the toxic substance to the larynx; and (2) from the selective affinity of various poisons in the blood for the laryngeal nerves or their bulbar nuclei. There is evidence to show that the axon does not receive all its nutrient material from the ganglion cell, but rather that it depends on local processes of diffusion. The toxic paralyzes of the larynx are due to neuritis, and may conveniently be divided into 2 distinct pathogenic groups. 1. Infective neuritis, commonly occurring in the course of diphtheria, and less frequently observed in typhoid fever, typhus fever, scarlet fever, measles, influenza, rheumatism, tuberculosis, syphilis, cholera, and malaria. 2. Toxic neuritis, most frequently due to lead poisoning, but also reported to have occurred in poisoning by copper, arsenic, antimony, phosphorus, alcohol, atropin, and morphin. The following are the conditions for the treatment of these toxic paralyzes of the larynx: 1. The resort to the general treatment appropriate to the infective disease concerned in the etiology of the condition. 2. The intralaryngeal application of the faradic or the galvanic current, combined with the internal exhibition of strychnin, either by mouth or, when feasible, injected directly into the affected muscles. 3. The relief of dyspnea and threatened

asphyxia in cases of bilateral abductor paralysis by intubation or tracheotomy. [J.M.S.]

16.—McKeown says that the **improvement in hearing following the removal of adenoids**, in a large number of cases, begins as soon as the operation is finished. He reports several cases on whom tests as to hearing had been made just previous to the operation and as soon after as possible. In all of these the evidence of improved hearing was so marked as to leave a very large balance to the credit of the operation. This improvement he believes is due not to the relief of intertympanic pressure, but rather to the relief afforded by the operation to the circulatory mechanism, the local depletion removing or diminishing the disorder of the circulation caused by the presence of the adenoids. [G.B.W.]

17.—In the first case, a Stacke's modification of tympano-mastoid exenteration was done for relief of the mastoid disease from which the patient was suffering. At this time the **lateral sinus** did not seem to be **thrombosed**, nor was there any sign of extracranial abscess. The wound was thoroughly packed, and after the operation the patient seemed much better. Within a day or two, however, hectic temperature developed, the wound was again opened, and this time a thrombus of the lateral sinus was found. The clot was notably purulent and required quite extensive removal before the blood current was reestablished. The patient finally made a good recovery. In the second case, the true condition was not discovered until the necropsy, though the patient was twice operated upon. It was then seen that the internal jugular on the right side from the bulb to its junction with the subclavian was a solid fibrous cord, while the left lateral sinus was occluded by a fresh antemortem clot. [G.B.W.]

20.—Pus escaping from the **mastoid cells** into the digastric groove is difficult of diagnosis until the physical signs have become well established and the case is far advanced. In the case reported by Waggett the symptoms resembled closely those of an adenitis secondary to the mastoid disease. But pressure on the swelling, which was limited anteriorly by the ramus of the jaw, caused pus to exude through the minute opening in the tympanic membrane. After opening the mastoid cells and antrum a fistulous tract was found leading to an abscess cavity about the size of a filbert and situated with its long axis pointing to the parotid region. The patient recovered readily from the operation and, except for an ugly scar, was none the worse for either the disease or operation. [G.B.W.]

22.—Durham and Myers have studied **yellow fever** in Cuba. Among the many conflicting opinions and statements concerning the disease it appears certain that neither the handling of or contact with yellow-fever patients nor the performance of necropsies is capable, *per se*, of conveying the disease to nonimmunes. It also appears probable that general ships' cargoes and the fomites of patients are also not directly infective. On the other hand, it seems to be fairly definitely established that a yellow-fever patient may become a danger by "infecting the house" in which he is placed. In such an infected house an interval of about 14 or 21 days obtains before the first secondary cases occur. This curious and somewhat prolonged interval is suggestive of a development of the infecting factor in or about some agent or matter in the house, the nature of which is not yet demonstrated. It is commonly stated that one attack of the fever confers a long and lasting immunity against further attacks. The completeness of this immunity, however, is called in question by the recent investigations of the disease. [J.M.S.]

24.—Marsden has studied the effects of the **treatment of diphtheria by the antitoxin** in 105 cases. Of these patients 85 were under 12 years, and 20 were adults. Among the adult patients 16 complained of sore throat as the first symptom of the disease, while 2 complained of sore throat accompanied by shivering as the first symptom. Among the children there was fever before the complaint of any symptom in 28 instances; in 16 cases the patients complained of sore throat as the first symptom; in 5 the first symptom was croupiness or hoarseness, and in 3 a discharge from the nose was first seen. Pyrexia at the beginning of an attack of diphtheria was found to be very variable. In more than half of the cases the antitoxin was injected during the first day of the disease, and in the majority of the cases during the first 2 days. There was but one death in the series of cases

studied, and this favorable result is accounted for by the early administration of the antitoxin. In the majority of cases the advisability or nonadvisability of injecting antitoxin must rest on the clinical diagnosis. The amount of antitoxin given in this series of cases varied from 750 to 14,000 units. In 59 of the cases the temperature returned to normal within 3 days after the administration of the antitoxin. The membrane disappeared in 83 out of 99 cases within the first 4 days. In 47 cases either no albumin or the merest trace could be detected in the urine; in 19 instances there was a very marked trace of albumin, and in 23 cases the amount was considerable. There were 7 cases in which the patients were suffering from the nephritis of scarlet fever, or in which they had just recovered from that complication when the diphtheria developed. In 4 of these cases the antitoxin had not the slightest deleterious effect upon the kidney, and in 1 case there was an exacerbation due to the antitoxin alone. One must, therefore, conclude that the antitoxin may have an irritant effect upon the kidney, yet this is by no means the rule, and in many cases the action is only temporary. Postdiphtherial paralysis was seen in 7 out of 104 cases that recovered. Laryngeal symptoms were present in 6 cases. The symptoms attributable to the antitoxin have not differed materially from those so frequently described. They have appeared from the sixth to the eighteenth day after the injection. An erythema was the most common symptom, and was found in 20 cases. [J.M.S.]

25.—Norway reports the case of a woman of 25 who had **tuberculosis of the lungs**. She had had hip-joint disease for 20 years, and the pulmonary condition was of 10 years' duration. There was a large cavity below the left clavicle; the morning temperature was 103° and the evening temperature was 105°. No food could be taken and no medicine could be administered because they produced vomiting and hiccough. The patient was **treated with Cervello's igazol** and in 3 weeks she was out of doors as much as possible and had gained 6 pounds in weight. The author has used igazol in 2 other cases. [J.M.S.]

2.—Barker calls attention to the improvement which has occurred in the results following **operations for carcinoma of the breast** in recent years. Still further improvement depends, above all things, upon the spread of knowledge among the general population and the profession. In regard to the danger of neglecting any tumor of the breast, he states, as pathologic axioms, the following: Carcinoma is for a short time a purely local disease; it soon begins to spread into the surrounding tissues by

way of the lymphatics. Three systems of lymphatics participate: the epimammary under the skin, the mammary in the breast substance, and the submammary in the fascia covering the pectoral muscles. The glands of the axilla receive most of the lymph from these systems and act as a dam to further progress for a time. In rare cases the flow of lymph takes place toward the lymph channels underlying the pleura. It is probably possible to reinfect healthy tissues during excision of the breast by the juices of the infected material or by contact of the cut surfaces of the infected area with the dissected surface. When carcinomatous infection has reached the underlying muscles spread to the internal organs has occurred. Bearing these facts in mind, it is now generally held that excision of the breast, to be effectual, must be early. The overlying skin, subcutaneous fat, the pectoral fascia, axillary fat and glands, with the entire breast, must be widely and deliberately removed. During this dissection all divisions of carcinomatous tissue should be avoided, and if unavoidable freshly sterilized instruments, etc., must be used. As little direct handling of the parts as possible should take place. Arrest of all hemorrhage should be accomplished by forcipressure and by ligature, elastic pressure, and bandaging. Rest for the wound should be secured for at least 2 weeks. Extensive removal can thus be accomplished with little risk to the patient in early cases. When the disease has infected the muscles, palliation alone can be expected from surgical intervention, and it is questionable whether extensive operations involving risk from shock should be performed with this end in view. Barker reports the results of 100 consecutive excisions of the breast since 1883; 90 of these excisions were for malignant disease; 26% of the patients have lived over 3 years, and yet succumbed to carcinoma; 15 patients are alive over 3 years after the operation; and 16% have lived over 5 years, giving 33% over 3 years. Only 7 of the patients suffered from local recurrence, the disease returning usually in the internal organs. In almost every case the diagnosis was confirmed by microscopic examination. With still further improvement in early diagnosis and treatment, a far larger proportion of the patients may be saved. [M.B.T.]

3.—Associated with *angina pectoris vera* we find sclerosis of the coronary arteries, alterations of the aortic valves, and aortitis, especially the form that causes an ectasia of the ascending portion of the arch. The coronary arteries may present sufficient lumen in other parts; but often the point from which they arise from the aorta is so diseased that the lumen at the beginning of the vessels is so reduced that a bristle can scarcely be introduced. As a result, weakening of the heart and defect of energy necessarily follow, so that every demand for additional effort is likely to be followed by an additional and sudden failure of energy. Schott has never been able to observe any absolutely characteristic condition of the circulatory system before, during or after the access. It must be especially noted that anginal attacks are readily excited by bodily exertion and by mental excitement. For the relief of the pain the author advises the use of hot water in a rubber bag so that the bag, at a temperature of from 140° to 170°, may be moved with light touches over the whole chest. In many cases this procedure results in marked relief or absolute suppression of the pain. In some cases morphin must be used. Sodium iodid is useful during the attacks. In the interval of the attacks it is necessary to stimulate the heart and to strengthen it. The author recommends camphor and caffeine as stimulants. Balneologic and gymnastic treatment is very valuable. He warns against hurrying the patient on to strong effervescent baths and to too cold or too warm baths. [J.M.S.]

4.—A healthy man who is constantly having to go up and down hills, working hard, eating probably somewhat largely, the food not always being very easy to digest, develops cardiac hypertrophy and slight gastric dilation. As time goes on the patient takes less exercise and his food becomes richer, although not diminished in quantity. If at the same time alcohol is used freely all the conditions are present that tend to produce dilation of the stomach and degeneration of the heart-walls. The condition is known as the "hill heart." The stomach should be treated by strict dieting as well as by gastric antiseptics. The meals should be taken dry and the fluids drunk when the stomach is empty. Concerning the heart, the most important thing is to diminish its work. Spartein sulfate has proved a good cardiac stimulant. [J.M.S.]

5.—Bell is strongly in favor of the **antitoxin** treatment of diphtheria. He has used it in all of his cases for the past four years without losing a single patient. He reports three consecutive cases of severe laryngeal diphtheria in which he performed **tracheotomy**. These were the only patients requiring operation. He is convinced that the success of the operation is due to the antitoxin given. A few years ago they would probably have died. The antitoxin loosens the existing membrane, prevents fresh membrane from forming, and so in severe cases tracheotomy will tide over the urgent dyspnea. [M.B.T.]

7.—Duffett reports a **recovery after diffuse suppurative peritonitis** from gangrene of the appendix. A boy of 14 was admitted to the hospital for acute pain and abdominal distention. While playing one of his playmates had sat upon his abdomen and the acute attack of pain had resulted immediately. The pain was chiefly about the umbilicus. He vomited frequently and was constipated; there was extreme tenderness; both legs were drawn up; and the lower half of the abdomen did not move on respiration. There was no distention or tumor to be felt. The patient's condition became gradually worse and it was evident that he was suffering from general peritonitis. Five days after the onset of pain the abdomen was opened in the median line below the umbilicus. Very foul pus escaped. No adhesions were present. The intestines were bathed in pus and there was a large collection of pus in the pelvis. The abdomen was thoroughly flushed with boiled water. A second incision was made over the outer half of Poupart's ligament, and the appendix was found lying free in an abscess-cavity which communicated with the general abdominal cavity through a ragged opening. A drainage-tube was passed into the pelvis and the iliac incision was drained by gauze. The remainder of both wounds was closed. The patient bore the operation well, but a few days later the pulse became rapid, the abdomen tender, and the temperature rose again. Another operation was undertaken, but on incision no pus was discovered. Gradual improvement resulted and the patient left the hospital about 6 weeks after the operation, with all wounds healed. [M.B.T.]

8.—Armitage believes that the ideal **treatment of gonorrheal arthritis** is incision of the joint under strictly aseptic precautions, removal, if necessary, of infected synovial membranes, irrigation with some sterilized solution and closure without drainage. This treatment is impossible in many cases, however, and in such cases he believes that medical treatment may be effectual. Several cases are reported which were treated successfully by the use of tonic mixture of iron, arsenic, quinin, etc. [M.B.T.]

10.—Lord reports a case of rapidly growing **sarcoma of the ovary** with extensive infiltrations, occurring in an unmarried woman of 56, who had suffered from insanity for many years. Microscopic examination of the tumor after removal showed a great diversity of component elements and the following cell forms: 1. Extremely small, darkly stained, round cells, about $\frac{1}{2}$ the size of a red corpuscle, which may have been nuclei of broken-down cells. 2. Cells a little larger than a red blood-corpuscle, staining poorly, with a small nucleus or nucleolus. 3. Still larger cells staining deeply and containing many granules. 4. Cells similar to No. 3 but oval. 5. Cells like large leukocytes with 2 or 3 nuclei present. 6. Large flat cells, oval or irregular, sometimes containing a nucleus. 7. Small branching cells; and 8 red blood-corpuscles, some showing a degree of poikilocytosis. [W.K.]

11.—Carmody confirms the observations of Francis concerning the existence of **hydrocyanic acid in sweet cassava**. The prussic acid is found chiefly in the skin and outer cortical layer. [J.M.S.]

12.—Jalland reports a case of **exploratory celiotomy** for severe abdominal pain in which no disease was found. Perfect recovery followed, and the patient gained very much in weight and general health. In a second case, a woman of 28 was operated upon successfully for a large cyst of the liver. The cyst was drained by incision after suture to the abdominal wall. In a third case, a male child, 11 months old, was taken with vomiting, and mucus and bloody discharge from the bowels. There was a distinct tumor felt in the left hypochondriac region. This condition had existed for 12 hours, when celiotomy was performed. The abdomen was opened in the median line, and the lower part of the

ileum was found invaginated in the cecum. Reduction was effected by pressure, and an uneventful recovery followed. In the fourth case cesarean section was performed on a woman of 21, who had an extremely distorted pelvis with a conjugate diameter of 2 inches. Both mother and child are perfectly well. [M.B.T.]

13.—Atkinson and Lowson report the case of a man of 25, who suffered from **typhoid fever**. The disease lasted 41 days, when convalescence began. After the temperature had been normal for 13 days a **relapse** began which lasted 20 days, and after an interval of 14 days he suffered from a **second relapse**, which lasted 13 days. The patient was sent from Hong Kong to England, after being in the hospital 149 days. [J.M.S.]

New York Medical Journal.

September 22, 1900. [Vol. lxxii, No. 12.]

1. The Treatment of Chronic Cystitis in the Female by Curetment of the Bladder and Instillations of Corrosive Sublimate. CHARLES GREENE CUMSTON.
2. Generalized Tuberculous Lymphadenitis, with the Clinical and Anatomical Picture of Pseudoleukemia. The Study of a Case. THOMAS R. CROWDER.
3. A Report of Three Cases of Ascending Urinary Infection Due to the *Bacillus Pyocyaneus* and the *Proteus Vulgaris*. GEORGE BLUMER and AUGUST JEROME LARTIGAU.
4. Membranous Enteritis. H. F. SLIFER.
5. A Resume of Some Papers Presented to the Thirteenth International Congress of the Medical Sciences.

1.—Cumston describes in detail his method of treating **chronic cystitis** with curetment of the bladder and instillations of corrosive sublimate. The instillations should be given daily beginning with a solution of 1 to 4,000 or 5,000. The strength of the solution is to be progressively increased according to the tolerance of the mucous membrane of the bladder. The solution should never be made with alcohol. The proper amount to be instilled is from 2 to 4 cc. and from 10 to 15 drops in the neck of the bladder and the deep portion of the urethra. He reports 10 cases treated by this method, and draws the following conclusions: (1) Sublimate instillations will often produce a very great improvement in the distressing symptoms met with in both tuberculous and nontuberculous cystitis, such as a diminution in the frequency of micturition, a decrease of pain, an increase in the capacity of the bladder, and an improvement in the condition of the urine. In some cases a complete cure may be obtained; (2) when the instillations fail to produce the desired effect, **curetment of the bladder** is indicated in both tuberculous and nontuberculous cystitis; (3) in gonorrheal cystitis instillations of sublimate are particularly efficacious, and rapidly subdue the pain; (4) under favorable circumstances a radical cure of tuberculous cystitis may be obtained by curetment when the vesical lesions are localized and the kidneys free from the disease. Curetment through the urethra will not allow the surgeon to reach the entire surface of the bladder, so that when the lesions are extensive they should be directly treated by suprapubic cystotomy; (5) much relief may be afforded by curetment to a large number of patients suffering from tuberculosis of the bladder, but who on account of the advanced stage of generalized infection are in no condition to undergo a more radical operation; (6) when cystitis is caused by a prolapus of the genital organs, and when hysteropexy, combined with anterior and posterior colporrhaphy, does not relieve the bladder-symptoms, curetment of the bladder, followed by sublimate instillations, is the proper treatment. [W.K.]

2.—Crowder concludes his paper on **generalized tuberculous lymphadenitis** by giving a summary of the findings of the case abstracted in this journal last week. He quotes extensively from the literature and there is an extensive bibliography. [J.M.S.]

3.—*Bacillus pyocyaneus* has time and again been demonstrated in connection with whole series of pathological conditions, but no mention can be found relating to its connection with an **ascending urinary infection**. The three such cases reported in which this bacillus was found are therefore of peculiar interest. All of the cases proved fatal. In the first case the main symptoms were referable to the

nervous system, the most important of these being partial paraplegia, loss of reflexes, anesthesia, and analgesia. It was noticed that no cord lesion was present to account for such a condition. The subsequent development of a bedsore and its infection with the *Bacillus pyocyaneus* is of interest in connection with the point of origin of this infection. Whilst conceding the possibility of its skin origin, it would seem more likely that the skin became infected by the urine from the urinary lesion, and such a belief is supported by the fact that the infection occurred a considerable time after the first clinical manifestations. Furthermore, the postmortem showed the urinary lesions to be of long standing. Case 2 was a simple case of ascending urinary infection following stone in the bladder. Case 3 presented clinically the symptoms of a hemorrhagic septicemia, probably incidental to a puerperal streptococcus infection. The *Bacillus pyocyaneus* was found only in the urinary organs. From an anatomic standpoint and in contradistinction to some other forms of pyocyaneus infection, the ascending urinary form produces no specific picture. The urinary lesions were merely inflammatory hyperplastic processes. One of the most striking things noticed was the relative nonvirulence of the *Bacillus pyocyaneus* isolated from these cases. This was probably because the cases were chronic, as in the acute infections from this germ it is rare to find nonvirulent forms of this organism. [G.B.W.]

4.—Slifer reports 3 cases of **membranous enteritis**—one in a woman of 30; another in a woman of 35; and the third, in a woman of 40. [J.M.S.]

Medical Record.

1. The Phelps Operation for Hernia and Method of Closure of Abdominal Wounds. A. M. PHELPS.
2. To What Extent Does "Rheumatic and Gouty Diathesis" Enter Into Traumatic Joints (Sprains and Bruises), Septic and Gonorrheal Joints, Acute Articular Rheumatism, Neuropathic Joints, Arthritis Deformans (Osteoid, Rheumatoid), as an Etiological Factor? What is the Scientific Basis for Such a Term? WILLIAM HENRY PORTER.
3. Primary Carcinoma of the Parovarium. B. S. TALMEY.
4. Simple Fracture of the Shaft of the Femur, with Report of Two Cases of Delayed Union. WILLIAM H. SHIPPS.

1.—Phelps believes that the reason why so many **relapses** occur in **operations for hernia** is because the scar tissue is stretched. Since 1892 he has operated upon 216 cases of hernia; 46 were relapsed from Bassini's operation; 51 from other operations, chiefly McBurney's. In all these cases he closed the abdominal wounds with silver wire. He believes that his method of closure is original. He uses continued sutures of fine silver wire which becomes encysted. In case the abdominal walls are extremely thin a mattress of loops of silver wire is introduced over the transversalis fascia. A glass drainage-tube is inserted down to the wire mattress. These relapses occurred after primary operations in our best hospitals and by prominent surgeons. Phelps predicts that the use of the subcutaneous silver-wire mattress will become general and that other methods will soon be abandoned. He has personally had 16 infections. In such cases he lays the wound open, cures out all the infected material and fills the wound with pure carbolic acid, afterwards washing it out with alcohol, and allows the wound to heal by granulation. In no case has a relapse followed. [M.B.T.]

2.—Porter, after first calling attention to the extremely unscientific nature of the terms **diathesis, gout and rheumatism**, undertakes by a consideration of various chemic theories and problems to determine what the nature of the last 2 conditions may be. Taking the most prevalent theory, namely—that gout is due to the non-elimination of uric acid from the blood-stream and its subsequent discharge from the blood as uric acid into the protoplasm of the various structures of the body, he first undertakes to determine what conditions give rise to the production of uric acid and where it is produced. In answer to the first, he looks upon uric acid as a product of suboxidation and disregards the fact that it is the principal excretory substance of birds and reptiles. He does not believe that it is found in the blood as

free uric acid nor as uric acid in combination, although he admits that it possibly does not exist as such. He thinks, however, that the most logical theory is that it is produced in the renal cells where it has a solvent action upon calcium phosphate that would otherwise form calculi. In cases of prolonged high tension, sub-oxidation occurs, and there may be an increased production of uric acid. Under these circumstances, it may be found in excess in the urine or may in fact be produced by the various tissues of the body. This theory, of course, is not in accordance with the bacteriologic theory. Porter admits that various microorganisms have been found associated with rheumatism, chiefly of the coccus form. Nevertheless, we know that chemic toxic substances are capable of producing definite trains of symptoms, and it is not unreasonable to suppose that such substances may be the cause of rheumatism and gout. Admitting this we can look upon gout either as the result of the prolonged ingestion of greater amounts of nutrition than the system can perfectly oxidize, or of some morbid condition reducing the oxidatory power of the tissues. The toxic substance itself may be either a by-product or an isomeric alteration of a normal product. Various conditions give rise to the alterations in the joints, perhaps the most excessive forms of these occur as the result of long-continued imperfect oxygenation of the tissues. These may act by preference upon a joint that has been the subject of some form of traumatism or infection. [J.S.]

3.—A woman, 43 years of age, having been operated upon for **carcinoma of the pylorus**, died a few weeks afterward. The autopsy revealed the presence of a malignant ovarian tumor on each side. Microscopic examination of the tumors showed the main mass of the growth to be composed of various irregular spaces lined with a single layer of high cylindrical epithelium within a richly cellular stroma. There occurred also solid nests of these cylindrical epithelial cells. Since these cylindrical epithelial cells are peculiar to the parovarium, while the epithelial elements of the ovary, the genital epithelium, as well as the follicular epithelium are cubical, the logical conclusion was that these growths were **primary carcinoma of the parovarium**. Talmy agrees with Ribbert in his claim that the main cause for the origin of a cancer is always the proliferation of the connective-tissue elements resulting in a separation of the epithelial cells from their organic coherence and their implantation within the connective tissue. The isolation of the epithelial cells once accomplished, they begin to proliferate within the connective-tissue and lead to atypical growths. If all the so-called ovarian tumors were systematically examined under the microscope, a great part of them would certainly be found to be of parovarian origin. [W.K.]

4.—Shippo reports two cases of simple fracture of the shaft of the femur with delayed union. The patients were treated with extension apparatus, and after nonunion seemed probable systematic massage was employed, together with the use of hypophosphites internally, with a successful result in both cases. Shippo recommends the early employment of **massage in fractures** as an aid in facilitating consolidation. It improves the nutrition of the parts and prevents stiffness or ankylosis of the kneejoint. [M.B.T.]

Medical News.

September 22, 1900. [Vol. 77, No. 12.]

1. Studies in Surgical Technic, with a Report on Operative Surgery at the City Hospital for 1898 and 1899. GEORGE EMERSON BREWER.
2. Toxicity Versus Septicity in the Infectious Pathogenic Bacteria. EUGENE WASDIN.
3. Total Extirpation of the Ureter. WILLY MEYER.

1.—The results obtained by Brewer at the New York City Hospital show very clearly the wonders of **modern antiseptic and aseptic surgery**. During his first month there, there were 43 cases operated on for various diseases and injuries, and not one clean case escaped infection. At this time there were absolutely no appliances belonging to the modern surgical operating room, and the technic was faulty to a criminal extent. As time went on Brewer was able gradually to get modern appliances and modern technic installed and the results are very well

shown in the following summary: First year, 147 operations, mortality 5.4%, infection in clean cases 39%. Second year, 109 operations, mortality 8.2%, infection in clean cases 9%. Third year, 165 operations, mortality 9%, infection in clean cases 7%. Fourth year about the same and the fifth year, 168 operations, mortality 7.1%, infection in clean cases 3.2%. The improvement in technic shows to a much greater advantage from the standpoint of clean wounds than it does from the standpoint of a lessened death-rate. [G.B.W.]

2.—Waddin believes that microorganisms cause reacting symptoms 2 ways, either they produce a toxin which permeates the whole system and gives rise to intoxication or with slight development at the point of inoculation they rapidly multiply and permeate the tissues giving rise to **septicemia**. As examples of **intoxication**, he mentions particularly the diphtheria-bacillus. He is not certain that we have any pure type of septicemia, but thinks that the plague bacillus approximates most closely, and that of typhoid fever must be regarded as in part a septicemic condition. Plague he considers primarily a pulmonary infection producing little reaction but rapidly becoming generalized. Many microorganisms exhibit both toxic and septic power; the relative proportions of the 2 varying; as for example, in typhoid fever. [J.S.]

3.—The operation of **total extirpation of the ureter** may be done either simultaneously with the nephrectomy (primary) or some time after this interference (secondary). In case of nephrectomy for malignant disease the ureterectomy will generally be a primary one, but only partial. In cases of tuberculosis it is best to remove as much of the ureter at the time the nephrectomy is done as is thickened and, to the naked eye, diseased. Total extirpation of the ureter in combination with removal of a tuberculous kidney is indicated only if the tube is visibly enlarged and suppurating. Meyer reports a case in which he removed the whole ureter, secondary to a nephrectomy, for hydropyonephrosis. The nephrectomy healed readily and for 15 months the patient was not seen. At the end of this time he again came under observation, and when examined the left ureter was found to be suppurating and rendering the urine turbid with pus. The operation was carried out through an incision devised by James Israel, and the whole ureter was exposed without entering the peritoneal cavity. After the ureter had been removed the entire abdominal wound was closed layer by layer with continuous sutures. The patient made an excellent recovery. The cause of the trouble was found to be a stone lodged in the lower part of the ureter causing ulceration which had cicatrized, causing stenosis. [G.B.W.]

Boston Medical and Surgical Journal.

September 20, 1900. [Vol. cxliii, No. 12.]

1. Treatment of Pott's Disease after the Development of the Deformity. EDWARD H. BRADFORD.
2. Joseph W. England's Fat-Free Tincture of Digitalis. ELBRIDGE G. CUTLER.
3. Knee-joint Surgery for Nontubercular Conditions. A Report of 38 Operations for Synovial Fringes, Injured Semilunar Cartilage, Loose Cartilage, Coagula, Exploratory Incisions, etc. JOEL E. GOLDTHWAIT.

1.—A study of the statistics of **forcible correction of deformities** resulting from **Pott's disease** of the spine is given; 639 corrections were performed by 34 operators. The time elapsed varied from a few days up to 3 years and more. Of the separate detailed cases, in 7 more than 1 year had elapsed; in 35, more than 6 months. Deaths reported from all causes, 25; various diseases, 5; general tuberculosis, 4; trauma of the operation and chloroform, 5; intercurrent disease, 7. Immediate results: Respiratory embarrassment, 7; pain, 6; severe shock, 3. Abscess present before operation, 19; ruptured, 4; benefited or absorbed, 6; appeared after operation, 2. Paralysis present before operation, 23; relieved, 17; not relieved, 2; made worse, 1. Paralysis appeared after correction in 4. Direct effect on deformity in 240 cases: Complete correction, 130; incomplete, 94. Result in 77 cases: No relapse, 20; some relapse, 50; total relapse, 7. From these figures it appears that more force can be used with safety in the attempt at correction of a kyphosis than was formerly considered possible (639 cases with but 5 deaths

Original Articles.

APPENDICITIS.*

By SAMUEL LLOYD, M.D.,

Professor of Surgery, New York Post-Graduate Medical School.

It was my privilege to be invited to read a paper before the New York Medical Union,¹ at their meeting on December 26, 1899; and at that time I gave the statistics of 25 cases of appendicitis that I had seen during the first attack and followed for years, until the final outcome was known.

These 25 cases offer some suggestions in regard to what happens in the so-called conservative treatment of appendicitis. Of the 25 cases, 6 terminated fatally. This is a mortality of 24%, and is somewhat startling when compared with the statistics of experienced operators. Fitz gives the mortality in his statistics, compiled in 1886, as 26%.

Eighteen of my cases had recurrent attacks. In other words, only 7 escaped without recurrence. This is contrary to the usually accepted statements of physicians who have reported that their cases of appendicitis *always* result in recovery under medical treatment. The explanation seems to me to be a comparatively simple one: They do not follow up their cases. Many of these cases I traced from one physician to another before their histories were complete. In this series of cases a gradual tendency to an increase in the frequency and severity of the attacks was noticed. I do not mean by that that every attack was worse than the last, but that the general condition gets worse, and the sum total of the attacks one year is apt to be greater than that of the year before. Nor do I mean to be understood as claiming that the attacks need necessarily follow one another in rapid sequence. On the contrary, several months or even years may elapse between attacks, but in the end the testimony of the patient will be that the colic is more frequent and more severe, constipation less readily combated, and indigestion more constant and more marked. The right spasm is more distinct and more tense; the patient is inclined to protect this side and keeps it turned away from danger as much as possible; the appendix becomes more readily palpable and more painful to the touch. Flesh is gradually lost, and the general tone is decidedly below the proper and usual standard.

Similar ideas have been advanced by many other authors. Mynter² says that most authors agree that all attacks of appendicitis predispose to new attacks unless the appendix happens to be totally destroyed by gangrene, complicated by a local circumscribed abscess, or unless obliterated by destruction of its epithelium, and cicatricial retraction of the new formed tissue. His cases showed recurrence in 35 out of a total of 75 (47%).

German statistics on this point are interesting. Thus, Rotter,³ at the St. Hedwig Krankenhaus in Berlin, gives the statistics of all the cases treated in both the medical and surgical wards of that hospital. He claimed that 84% of all cases which were brought to the hospital in the first 6 days of the disease recovered spontaneously, and the whole number of spontaneous recoveries, that is of cases admitted at any stage of the

disease, was 74%. If the cases of circumscribed abscesses alone are considered, the percentage of recovery without operation rises to 90%. In the Moabit Hospital in Berlin, in three years and a half there were 149 cases, with a mortality of 14%. In these cases in the Moabit Hospital, Sonnenburg operated 94 times, or in 63% of all the cases, while Rotter only operated in 25.3% of his cases.

Ewald,⁴ in considering these reports, draws two conclusions: (1) That it is unnecessary always to operate at the earliest possible moment, and (2) that in cases of periappendicular abscess, spontaneous resolution occurs in an appreciable number of cases. He adds that "it cannot be doubted that a resorption of the pus . . . took place. In what manner this is accomplished, whether by autodrainage into the cecum through the perforated vermiform process, by direct perforation into the gut, or by resorption on the part of the peritoneum, must remain problematical."

Rotter also gives some data in regard to recurrences. In the histories of his cases, only 21 or 24 were recorded as having had previous attacks. They rarely had more than two attacks, and the second usually occurred within a year after the first. Attacks occurring later than that were rare.

These statistics are so absolutely at variance with those of other observers and with my own, that they are given only to show how a medical man can be led astray. These cases were largely observed in large hospitals and in Germany. In that country they do not generally class appendicitis as a surgical disease, but treat it medicinally, until an abscess is formed when they open and drain, and it is of course a fact that the statistics of cases seen in hospital practice are essentially different from those seen in private practice when the future condition of the patient is to be considered.

Every one admits that the majority of cases will recover from their first attack, and even from several attacks; every operator has seen large abscesses disappear, but the difficulty is that when these patients are observed by the physician he records them as triumphs for his skill in therapeutic application and forgets to observe them for the next five or ten years. That is the difficulty with Rotter's cases. They were not watched long enough. This, I think, I was able to show in my recent article on this subject, and I have no doubt that if everyone would take the same precaution, to follow up his cases, no matter how much it might hurt his pride to ask his successor in the patient's confidence, about him, we should have statistics so abundant that this question would be incontestably settled.

We concede the fact "that it is unnecessary always to operate at the earliest possible moment," but that is not the point. The question is how are we going to tell whether the patient will recover from the present attack or whether operation must be done to save his life. There is another question also that enters into this discussion at this point. Which method of treatment, in the end, is going to be most economical for the patient from the standpoint of both physical and financial wellbeing? In other words, Which will cause the least loss of time, the least risk, and the least pain and discomfort?

If it could be proved that these statistics from St. Hedwigs Krankenhaus and from the Moabit Hospital in Berlin, as interpreted by Ewald, were correct, there

* Read before the Alabama State Medical Association April 19, 1900.

would be no question about it. But Toft⁶ found the appendix diseased 110 times in 300 autopsies and in a stage of active ulceration in 5% of the examinations. Hawkins,⁶ in 100 bodies of patients dead from other than appendicular disease, which he examined at St. Thomas' Hospital, London, found 16 in which there was past or present disease of the appendix. Fitz⁷ in 1886 placed the recurrences at 11%, but later he raised it to 44%.⁸ Krafft's⁹ statistics also disprove these statements of Rotter's, for he found that 24 of his 106 cases had had previous attacks, generally one to three years before, but in one case 20 years had elapsed. Treves has mentioned a patient that had had 14 attacks and McBurney one with 12. My cases showed, as we have already said, recurrence in 18 out of 25 cases, 72%. This is so much greater than the results already mentioned that it cannot but cause comment. It is explainable, however, when one considers that my cases were watched for years and careful records kept of their condition. Hawkins, out of 250 cases, found a history of previous attacks in 23.6%. Wood¹⁰ studied the question especially and reports as follows: Irish, 50%; Price, 50%; Richardson, 49.8%; Ransohoff, 13%; Knaussold, 23%; Porter, 9.5%; Bryant, 11 to 17%; Sahli, 20%; Gage, 33.5%; Wyeth puts it at 80%, and Willy Myer¹¹ at 90%. Finally, Lennander¹² says that all the cases he has observed long enough have had relapses.

Could we throw out of consideration the question of relapses, we could then adopt Ewald's views, but unfortunately all surgeons have been obliged within the past few years to recognize the fact that recurrence is the rule and not the exception, and it is this that has led to the axiom *that operation should be performed in every case of relapsing appendicitis*.

A question that is raised by this statement is how many times should the patient have an attack before we operate? McBurney has said twice, and to my mind this is the limit, although I am free to confess that I feel safer for my patients after they have had one well-marked attack when I know that the appendix is removed.

Large masses in the right iliac fossa during an attack of appendicitis have disappeared; how or when we do not know. Is it always safe to wait for this disappearance? Are we not quite as likely to have a rupture of a tense abscess into the general peritoneal cavity, or have it burrow upwards until it penetrates the diaphragm and empties into the lung? I have seen this happen in my own cases. Even when it empties into the gut it does not mean freedom from recurrence by any means; 2 cases terminating in this way in my own experience had to be operated upon later for recurrence.

On April 16, 1896, I read a paper before the Medical Association of Georgia.¹³ As the basis for that paper, I took 558 cases from literature and tabulated them. Since then I have examined 1,011 in the same way, of which 878 resulted in abscesses, perforation, peritonitis, etc.

The following table gives the pathological details:

Perforation or abscess	315
" " with ulceration.....	17
" " " peritonitis.....	69
" " " concretion or foreign body	133
" " " gangrene.....	68
" " " gangrene and concretion..	18
" " " inflammation.....	6
" " " hardened feces	17

Perforation or abscess with concretion and peritonitis	27
" " " foreign body and peritonitis	15
" " " lumbricoid worms	6
" " " hernia	5
" " " rupture in bladder, rectum or vagina	15
	711
Foreign bodies	26
Fecal concretions	5
Inflammation	36
Enteroliths	3
Gangrene.....	34
Gangrene with concretion	8
Inflammation with concretion	4
	116
General peritonitis with foreign body and gangrene	22
General peritonitis with ulceration	29
	51
Total number of cases.....	878

This leaves only 133 cases in which the condition was unknown or where there was no definite pathological condition found.

As the result of this study, I tabulated the conditions usually met with as: 1. Cases in which the disease follows trauma. 2. Cases following septic inflammations in other parts of the body, such as salpingitis in the female, postpartum septic inflammation of the uterus, typhoid fever, tuberculosis, etc. 3. Direct infection of the mucous membrane of the vermiform appendix by its contained bacteria. 4. Alterations in its position and shape, so as to occlude its lumen, preventing the escape of its natural secretions and contained intestinal contents. 5. Alterations in its position, and pressure upon its mesentery by growths and impacted feces in the cecum. 6. Alterations in its position or shape so as to shut off its blood-supply. 7. Foreign bodies, including fecal concretions.

A most interesting case of the sixth division was operated upon by me at the New York Post-Graduate Hospital this winter. The patient was a boy about ten years of age who was sent to me by Dr. Shufelt. He had been ill only two or three days, and on admission his temperature was only 101°, but his pulse was over 130 and weak. A tumor could readily be mapped out in the right iliac fossa. Operation was performed immediately, and the appendix was found to be gangrenous from the tip to within half an inch of its base. The gangrene was due to the appendix having been twisted three times on its own axis, so that its own mesentery was wound around it, forming a firm band and completely strangulating it.

Taking this classification of cases, the question of treatment in each set naturally interests us. A traumatism in this region does not differ in any essential from a traumatism in any other part of the abdominal cavity, producing contusion or injury of the intestine, and should be subjected to the same rules and to the same treatment. So, too, in rheumatic or septic or infectious disease, the treatment would be the same as for similar lesions anywhere else in the abdomen. If the obstruction to the circulation is prolonged or permanent, so that the vessels are occluded, it is perfectly evident that there can be but one result, sphacelation of the whole organ beyond the point of circulatory obstruction. It is not necessary here to have any septic infection in the beginning, but the sphacelation of the

organ will naturally produce the same train of symptoms that would follow gangrene elsewhere. It offers the proper field for the development and growth of the different bacteria, and in a very short time it naturally becomes the seat of pathogenic and pyogenic changes. Naturally this evolution depends upon the rapidity with which the disease progresses. If the obstruction is complete, the gangrene is rapid and perforation occurs before the appearance of an abscess or inflammatory change that is sufficient to agglutinate the folds of the intestine lying about the iliac fossa. The natural result of this is perforation into the general peritoneal cavity with all the symptoms of an acute general peritonitis. If, on the other hand, the progress of the disease is less rapid, agglutination of the surrounding folds of the peritoneum will wall off the appendix, and then if perforation results the general peritoneum is protected. This is true of all the other conditions. The longer the irritation, the less rapid its extension, the more certain is the involved area to be protected by inflammatory adhesions.

The formation of a tumor, then, is not solely and in every case due to the presence of an abscess. In the great majority of cases it is impossible to recognize fluctuation. In the earlier stages, and when the disease progresses slowly, inflammatory lymph without the formation of pus may be thrown out around the diseased organ, forming an almost impenetrable barrier to the escape of the contents of the appendix into the peritoneum, and producing a well-marked induration. It does not necessarily follow that because a tumor is present in the right iliac fossa, the case will not resolve and recover without operation. On the contrary, a simple inflammatory induration and adenitis following a not too active germ-infection, may on the disappearance of the original point of infection be so well provided for by the natural conditions that it will gradually be absorbed, and frequently completely disappear. That is, of course, provided no secondary attacks occur.

The patient is not always safe, however. This probably accounts for many of the cases of which Ewald speaks, of resorption of pus, even when the tumor seems to have developed so slowly as to be comparatively well walled in by the agglutinated fold of peritoneum. The erosion of the pent-up fluids may cause perforation into the peritoneal cavity, and naturally, if this happens, a virulent septic peritonitis must result. Spontaneous evacuation into the lung, bladder, intestine or bowel may follow, but it is hardly safe, in view of the rapid mortality following perforation into the peritoneum, and the risk of such an accident, to take any chance of waiting for this to occur. If an examination of the blood shows marked leukocytosis it will help in the diagnosis of abscess.

I do not suppose that the question of the advisability of operation in this disease, in the cases where the appendix is gangrenous, where abscess has already formed, or where a fecal concretion or a foreign body are probably present would be opposed by any one. It must be perfectly obvious that in these cases, unless the causes of the irritation are removed by mechanical means, the patient is in imminent danger and likely to develop general septic peritonitis at any moment. By a reference to the table it will be seen that these cases make up the vast majority of all the cases of appendicitis.

It is also probable that in the present state of surgery

the majority of medical men are in favor of surgical intervention in cases tending toward general peritonitis, even though the symptoms do not point to perforation or abscess formation, in the hope that drainage of the abdominal cavity and the removal of an irritating focus of disease may forestall what would otherwise be a fatal complication.

This leaves a comparatively small number of cases in which the question of what should be done would be debatable. It is for these reasons that I do not believe any case of appendicitis should ever be considered as purely medical. Given a case of appendicitis, whether it has a history of recurrence or not, the medical attendant should be prepared for operation at any moment, and if not himself an expert abdominal surgeon, he should at once arrange with some one who has had the necessary experience to hold himself in readiness to operate.

It has been abundantly proved that the best time to operate is in the interval between attacks, but it is sometimes very difficult to say whether, if we wait, the patient will live to have an interval. I know of no absolute rule for this, and personally I am guided more by the condition of the pulse and the abdominal rigidity and tenderness than by the temperature. If the pulse is rather weak and rapid, the countenance very anxious, the tongue badly coated, the abdominal tension marked and the induration as felt through the rectum excruciatingly painful and the leukocytosis marked, I believe delay to be dangerous. Operate then and operate at once.

In the course of my clinics at the New York Post-Graduate Medical School and Hospital, on the subject of appendicitis, I am in the habit of giving this rule. In all cases of appendicitis where the symptoms are progressing unfavorably, after 24 hours have elapsed, operate and operate immediately, but in those cases where there is an undeniable amelioration during this time wait until the interval and operate then. In recurrent cases operation should be the invariable rule.

We are forced to the conclusion that operation is the only rational course to pursue, for, as McBurney has said, "no purely medical treatment of actual value in preventing or controlling the disease has yet been presented to the profession." And he might have added that with the definite information we now possess of the etiology and pathology of the disease none will be presented until, in the natural course of events, the appendix is evolved out of existence.

The next question then is how to operate. The evolution of individual surgical opinion on the subject is interesting. Most of us have begun by considering the question from a most conservative standpoint, only operating under the severest necessity; then, with increasing experience and a riper personal knowledge of the progress of the disease, we have found ourselves gradually advising earlier and more radical procedures. Is this the result of mature thought, or is it the rashness born of familiarity? The general tendency of all surgeons who once begin to work in this field toward the same general conclusions, that the earlier the operation the greater the number of complete recoveries and the shorter the loss of time, proves that it is the result of ripe experience.

In 1827 Melier¹⁴ described the forms of appendicitis and mentioned both perforation and recurrence as possible complications. He suggested the possibility of treating the disease by surgical means "if it were

possible to establish the diagnosis." In the case of Hancock, 1847,¹⁵ so often quoted as one of the earliest operations for appendicitis, the incision was made "from the spine of the ilium to the inner side of the internal abdominal ring, to relieve intestine, if sound, or omentum, or, if pus, to evacuate it." "Upon opening into the abdomen a quantity of excessively offensive turbid serum with fibrinous flocculi poured out and also patches of false membrane." This was therefore not a planned operation for appendicitis, but rather an exploratory laparotomy. Parker¹⁶ also operated about the same time, but did not publish his case until 1867. He then advocated cutting down to the peritoneum and then puncturing with an aspirating needle. Parker operated again on a patient of Burge's,¹⁷ and then Leonard Weber¹⁸ operated by cutting down to the peritoneum and waiting for the abscess to rupture. Buck,¹⁹ in 1874, reported 3 cases together with 1 each by Krackowizer, Ward, Sands, Kelsey, White, and 1 of his own. He varied the technic by enlarging the trocar puncture by incision with the knife. It should be noted that in 1856 Dr. George Lewis,²⁰ in an article on abscesses in the appendix vermiformis, said in regard to treatment that he was inclined to favor the making of a free incision down upon the tumor. Parker's method continued to be the mode of operating, and in July, 1880, Sands,²¹ in reporting 26 cases, said that "in every case that has fallen under my observation the operation has been performed essentially in the manner recommended by Dr. Parker." "An incision several inches long, and usually parallel with Poupart's ligament, was made over the most prominent part of the tumor, through the skin and subcutaneous fat. Subsequently the deeper layers were divided until the fascia transversalis came into view. If fluctuation then became evident, the abscess was immediately opened, otherwise the fascia was penetrated in various directions by means of a hypodermic syringe until the seat of the abscess was discovered, when the operation was completed by entering a narrow bistoury alongside the needle." He adds at this time that "an external incision of two inches will afford ample space, and the wound should grow narrower as it increases in depth, while the direct opening into the abscess need not be longer than will readily admit the forefinger." Bull²² in 1873 read a paper in which, while he still advocated the method proposed by Parker, he brought out the fact emphatically that as soon as suppuration was made out the tumor should be incised. This was the general position of surgeons in 1882. At this time the truth was just beginning to dawn; the profession were just realizing that instead of the cecum being the point of involvement, the disease was almost invariably confined to the vermiform appendix. This evolution in opinion was not sudden, but gradual; the accumulating experience of operators with the so-called perityphlitic abscess was revealing the true state of affairs. From an operative point of view the field was clouded by the assertion made by Sands that these abscesses were always extraperitoneal, developing in the cellular space below the mesocecum and spreading from that point along the fascial planes of the back of the abdomen outside of the peritoneum. His advice in regard to operating and trying to avoid the peritoneum was followed by many, and as it delayed the thorough inspection of these appendices by this brilliant surgeon, it delayed by just so much the true knowledge of appendicitis. Therefore, in 1879, when Biermer, in 1880, Matterstock, and

in 1882, Talamon described the part played by the appendix in the production of perityphlitis, surgeons were almost ready to accept the proposition. In 1885, Treves exploded the extraperitoneal theory, and in 1886 and 1888, Fitz, of Boston, conclusively settled the position of the appendix in disease of the right iliac fossa. Sands, in 1887, conducted the first planned operation for the removal of the appendix. Treves, of London, advocated a similar procedure the same year.

A resume of appendicitis from this time until the present would be practically a history of American surgery and American attainment in abdominal surgery. In 1891,²³ in a discussion before the New York State Medical Society, McBurney took front rank as the exponent of appendiceal surgery, a position he has continued to hold up to the present time. McBurney's point was as important from the position of the diagnostician as his plan of operating is to the surgeon of the present day. He said: "I have found the *exact* locality where the greatest sensitiveness to pressure exists to be a valuable means of diagnosis, so that in every case of abdominal pain, not otherwise satisfactorily explained, I make a careful search for it, and in the first hours of all attacks of appendicitis, if firm pressure is made with the finger tip, and especially if the patient is made to cough while such pressure is being exerted, it is invariably easy to determine that the most sensitive point is a definite one in most cases. This point is very accurately determined, in the adult from one and a half to two inches inside of the right anterior superior spinous process of the ilium on a line drawn to the umbilicus. In children it is, in proportion to their size, so much less distant from the spinous process."

Edebohls²⁴ also made an important addition to our diagnostic resources when he, in 1894, described the method of palpation of the vermiform appendix. In carrying out his procedure the patient must lie "on her back. Placing three or four fingers of our right hand flat on the abdomen, we feel for the margin of the right rectus muscle, in the line between the navel and the anterior superior spine of the ilium. The fingers are introduced with a light, steady pressure under the margin of the rectus until we feel distinctly the pulsation of the common iliac artery. The appendix is felt, as a rule, just outside the artery, its insertion about an inch distant, while its tip often crosses the artery. We move the fingers slowly outward as soon as we feel the pulsation of the artery, and note with care the condition of the posterior abdominal wall—that is, the ilio-psoas muscle covered with the iliac fascia. This is the point of resistance against which we compress the appendix and which makes it possible to palpate it."

The operation divides itself naturally into that for the nonsuppurative and the suppurative cases. When, following this discussion at the New York State Society, operations became more frequent, it was soon evident that the large incisions and the interference with the integrity of this portion of the abdominal wall, rendered the patient extremely liable to hernia through the cicatrix. This led to a general revision in the method of operating and a study of the best means to avoid this accident. Kammerer,²⁵ Mynter, and others at this time suggested an incision just under the outer edge of the rectus muscle, drawing the muscle inward. The disadvantages of this incision are that, when the sheath of the rectus is opened, branches of the deep epigastric artery are cut, and this often gives a hemorrhage neces-

sitating a prolongation of the incision to control it. The incision is also at a greater distance from the appendix itself, especially if it is curled under the cecum and bound down by adhesions.

Willy Meyer²⁶ has recently suggested a method of opening the abdomen in complicated cases of appendicitis, which he calls the "hockey stick incision." He makes first a modified McBurney incision, and then, "after having entered the abdominal cavity, it will become evident whether or not the incision is large enough to enable us to do the necessary work. If the appendix is found to be situated inward or downward, and a wider entrance be needed, the incision can be lengthened straight upward as far as the surgeon thinks proper." With reference to lengthening the lower end he proceeds as follows: "Entering the peritoneal cavity at the lower angle of the wound with my left forefinger, I slide it inward to where the epigastric artery pulsates. I then curve the lower end of the incision by drawing the knife in a horizontal line; that is to say, perpendicular to the median line of the body, thus forming a rounded-off angle of about 135 degrees. The entire wound then has the shape of a hockey stick. In the horizontal part of the incision care is taken not to injure the epigastric plexus. It is primarily caught between two forceps, then cut and ligated. The incision ends at the border of the right rectus muscle. If still more room be needed, the belly of the rectus can easily be drawn inward, and the fascial layers beneath it be incised in the same direction, as the case may demand. In pulling the borders of this wound apart, it will be seen that an easy access has been gained to the organ situated within the small pelvis."

Personally I prefer a combination of the Morris²⁷ and McBurney²⁸ incisions. A curved incision, $1\frac{1}{2}$ inches long, is made so that the center of the incision is directly over McBurney's point. The aponeurosis of the external oblique is then carefully exposed, and split in the direction of its fibers, never cut. This brings the muscular surface of the internal oblique into view. These fibers are also split in a direction as they run at right angles to the fibers of the external oblique. Now instead of using the retractors as suggested by McBurney, the guy-lines of strong silk or catgut are put into position, one on each side of the divided internal oblique, and taking up as much of the divided muscle in each stitch as possible. This exposes the transversalis, which is also split in the direction of its fibers and also caught by two guy lines. The transversalis fascia and peritoneum are now taken up together and divided as much as possible in the long axis of the wound. The use of the guy-lines in the place of retractors, taking up less room, we are able to get along just as efficiently with a small incision. If now it becomes necessary to enlarge this wound, the fibers may be split and the skin-incision enlarged, until the muscular fibers are separated from insertion to attachment. In closing the wound we should always remember that the aponeurosis splits more and more as we manipulate the wound, and we should, therefore, draw the skin down and then up until we are certain that our sutures have reached the highest and lowest point of separation.

The management of the appendix is also important. Some operators are satisfied simply to ligate it, and then after cauterizing the stump to render it aseptic, drop it back into the abdomen. Others have adopted

the purse-string method of Dawbarn.²⁹ This consists of a circular continuous Lambert suture (silk) which is introduced through the superficial layers of the cecum a quarter of an inch from the insertion of the appendix, and tied loosely; the appendix is then amputated a half an inch or more from the insertion, and then dilated by introducing a pair of fine forceps into the cecum and opening the forceps. The stump of the appendix is then seized by fine-toothed forceps, and invaginated half an inch into the cecum, while the cecum is pressed against the forceps by the fingers of the other hand. The circular suture is then tied firmly and the toothed forceps removed. Edebohls advocates invagination of the whole appendix into the cecum. I have been always in the habit of closing the appendix as follows: Having tied off the meso-appendix in section, and cut it free from the appendix. I cut through the peritoneum covering the appendix about half an inch from its base. This peritoneum is then pulled back until about a quarter of an inch of the cecum is exposed. Then a fine curved needle armed with 00 catgut is passed through the muscular coat of the denuded cecum and base of the appendix, and brought out about one sixteenth of an inch below the point where the peritoneum was cut. The needle is then carried across and inserted the same distance below the cut peritoneum and carried down through the muscular coat until it comes out at the margin of the reflected peritoneum. Then the needle is carried to the other side of the appendix, where a similar stitch is taken. The field of operation is carefully protected by a piece of gauze, and the appendix removed at the line of section of the peritoneum. Its lumen is then swabbed out with pure carbolic acid, and then with alcohol, and dilated. Now, while the operator holds the two loops of catgut by means of a pair of forceps so that they will pull on the margins of the appendical stump, the assistant draws the two ends taut. This invaginates the whole stump of the appendix, and draws the cecum together over it at the same time. The two ends of the stitch are now tied, and the reflected peritoneum is turned back so as to completely cover the denuded portion of the cecum. This is closed over by means of a continuous Lambert stitch, which may be carried down so as to cover over the cut places in the mesentery, if desirable.

In cases of suppuration we should invariably be supplied with hydrogen dioxid at 10 to 15 volumes strength. As soon as the pus is found the dioxid should be poured in until it is evident from its action all pus has been destroyed. At the Post-Graduate Hospital this is routine practice in all cases of appendicitis accompanied by abscess or general peritonitis. And I am confident that by its use I have saved cases that would otherwise have been inevitably lost. Within the past month I have operated upon a case of general peritonitis where 4 pint bottles of peroxid were used in the general peritoneum. This froth and foam was then washed out with hot normal saline solution. This patient made an uninterrupted recovery.

There can no longer be any question in regard to the advisability of operating in appendicitis. This is no place for the recital of cases, nor have I the time, but my own statistics now show 160 appendectomies with 4 deaths—2.62%. This, compared with any medical statistics that can be advanced, will, I think, offer a sufficient argument for the early and radical operation for disease of the vermiform appendix.

ON SOME CASES OF PLEURAL EXUDATE WITH THE
PHYSICAL SIGNS OF PNEUMONIA.

By HERMAN B. ALLYN, M.D.,

of Philadelphia.

Instructor in Physical Diagnosis, University of Pennsylvania; Physician to
Philadelphia and St. Joseph's Hospitals.

THE physical signs of serofibrinous or purulent exudate in the pleura are usually so different from the physical signs of pneumonia that one is likely to feel, early in his practice, an unwarranted confidence in his ability to diagnose one condition from the other. Among the most important physical signs of an exudate in the pleura are diminished or absent vocal fremitus, diminished or absent vocal resonance, and faint or absent breath-sounds, except posteriorly over the compressed lung. On the other hand, in pneumonia the most important and constant physical signs are increased vocal fremitus and resonance, and bronchial breathing. But, just as there are cases of so-called massive pneumonia in which the vocal resonance and fremitus are not increased, and in which bronchial breathing is absent, so there are cases of pleural exudate in which vocal resonance and fremitus are present or increased and in which the breathing is bronchial or tubular. It is to the latter class that I wish to direct special attention. For the most part such cases are discovered at autopsy, but there are a few clinical reports.

In 1882, Austin Flint¹ reported the case of a man aged 31, who had a pleural effusion with the following physical signs: flatness on percussion over the whole of the right side. Over the scapula and in the infraclavicular region, the respiration was bronchial, and there was marked bronchophony. Over the remainder of this side there was absence of respiratory murmur, but vocal resonance and fremitus were somewhat greater than on the left side. The circumference of the right side was increased and the apex of the heart was displaced an inch and a half to the left of the nipple. Puncture obtained serous liquid, and the patient rapidly convalesced. Flint says the vocal resonance below the scapula and clavicle was not bronchophony conducted from the compressed lung. It had the characters

of normal vocal resonance and was accompanied by a proportionate amount of vocal fremitus. Comparing these signs on the two sides during the continuance of the effusion and after its removal, there was evidently some diminution caused by the liquid, but not enough to render the signs on the two sides equal. Flint does not explain the increase of vocal resonance and fremitus, but suggests that they may be due to the patient's voice, which was notably strong and of low pitch.

Flint alludes also to a case of empyema in which the loud voice and the whispered voice were conducted over the whole of the affected side of the chest with such intensity that there had been doubt as to the presence of liquid, although the patient had been previously aspirated. The aspiration was repeated and a large quantity of pus was withdrawn.

Vincent Y. Bowditch² reports four cases in which the typical signs of a pleuritic effusion, especially that of a diminished respiratory murmur was supplanted by marked bronchial respiration. Synopses of his cases are as follows:

CASE 1.—Man, aged 31, with pneumonia of the right lung with the usual signs of that disease. Bronchial breathing persists after fall of temperature and apparent convalescence of patient. Aspiration proves presence of 1½ pints of clear serum in the area showing bronchial respiration.

CASE 2.—Man aged 21, with a typical case of pneumonia. Harsh bronchial respiration persists several days after fall of temperature and marked improvement of general symptoms. Tentative aspiration over site of bronchial breathing was resorted to, with withdrawal of 12 ounces of brownish serum and immediate diminution of bronchial respiration.

CASE 3.—Male, 14. Pericarditis and endocarditis with pleuritic effusion in left lower back, proved by aspiration in spite of marked bronchial respiration in that region. In this case the effusion was moderate and was suspected from the upward curve of dullness in the lower axillary region. The fluid was blood-stained.

CASE 4.—Female, aged 20. No definite physical signs for a week after entrance. Development of dullness in right back diminishing upward, with crepitant rales, bronchial respiration, and slightly amphoric voice over area of dullness. Tentative aspiration proved presence of fluid. There was no special difference in fremitus, and no sign of fluid as distinguished from pneumonia except slight change of percussion noted on change of posture.

DaCosta³ says: "There are, however, exceptional cases of pleuritic effusion, in which bronchial breathing is heard all over one side of the chest. Especially does this happen if pneumonic consolidation accompany the effusion; but even in simple compression of the lung, and where the collection of liquid is not extensive, bronchial respiration may be perceived." He suggests that the lung-tissue is probably compressed around the bronchial tubes.

Musser says the breath-sounds may be heard, and are then weak and distant, or bronchial. Tubular breathing is said to be almost constant in children.

The explanation of the free transmission of fremitus, voice and breath-sounds in pleural effusions is not satisfactory. Flint, as already mentioned, suggests that the quality of the voice, which was notably strong and of low pitch, had something to do with the increase of vocal resonance and fremitus in his first case. West, after remarking that sometimes, although the quantity of fluid be very great, loud bronchial breathing is heard all over the affected side, says that "the loudness depends not inversely upon the quantity of liquid effused,

² *Boston Medical and Surgical Journal*, April 22, 1897, p. 336.

³ *Mett's Diagnosis*, 8th edition, p. 408.

but directly upon the openness of the air-tubes; for liquid is a good conductor of sound."

Osler says that in children there may be much effusion with retention of fremitus; and that in rare cases the vibrations may be communicated to the chest-walls through localized pleural adhesions.

I recently encountered the following case of empyema, with unusual physical signs:

M. H., white, female, 29 years old, a native of Philadelphia, was admitted to the Women's Medical Wards of the Philadelphia Hospital, in the service of Dr. J. H. Musser, on December 12, 1899. Her chief complaint on admission was dyspnea, pain in the left side, and prostration. The family history threw no light on her present ailment. The father had died when the patient was a child; the cause of death was unknown. The mother had died of worry over the death of a daughter. One brother as the result of an injury to the superior maxilla; another brother of some unknown cause. One brother is living and well. One sister died at the age of 17, of some unknown cause. The patient's habits were good, she was single, was a domestic, and stated that she had always been in good health. She was plump and well-nourished, and seemed to be above the average in intelligence. The patient's account of her illness was as follows:

On December 11 (nine days before her admission to the hospital) she got her feet wet and took cold. Two days later, she was taken ill, had fever and vomited, but there was no history of a distinct chill. She was in bed for a few days and then able to be up for a day. Four days before admission she had a very severe chill followed by pains in the left chest. These pains continued up to the time of her admission to the hospital, and then subsided.

On examination it was noted that the pupils were equal and reacted readily to stimulus. The tongue was protruded easily; it was moist, coated on the dorsum, with edges and tip clean. Herpes labialis was quite marked. The pulse was quick and frequent with diminished volume and low tension. The chest was well developed, symmetrical, and the expansion diminished. The superficial veins were prominent. The breathing was shallow and largely abdominal. Cough was slight. There was no history of bloody expectoration. The left lung was flat on percussion from base to apex, anteriorly and posteriorly; the resistance was much increased. Fremitus was increased. The breathing was typically high pitched and tubular. Posteriorly below the angle of the scapula and along the posterior axillary line were heard numerous moist subcrepitant rales. Bronchophony was marked and pectoriloquy could be demonstrated. There were also areas over which superficial rubbing could be heard. The coin-test was not made. The right lung, just below the root posteriorly showed areas over which moist rales were heard. The breath-sounds over the lower lobe were bronchial. The apex-beat of the heart was slightly displaced to the left. The heart's action was accelerated, but there were no abnormal sounds. The abdominal viscera appeared normal. There was no edema of the extremities.

On the 21st the heart was noted as regular, but rapid, the sounds being short and sharp. The second pulmonic sound was not accentuated. The entire left lung excepting a small area at the apex was flat on percussion. There was slight pain in the chest. The patient vomited after taking milk.

On the 22d the heart was about the same, but respiration was more labored. A few large bronchial rales which change on coughing were noted. Respiration was slightly harsh over the right lung, but there was no impairment of resonance on percussion. The patient expectorated tenacious sputum and perspired freely.

On the 23d, the patient was about the same. Cough was more annoying.

On the 24th she was slightly weaker. Perspiration was less free. More moist rales were audible over the base of the left lung. Cough worse and expectoration freer. There was some cyanosis. During the night, while resting comfortably, the patient suddenly died.

The urine on the 21st contained numerous hyaline casts and albumin $\frac{1}{10}$ by volume. There was no sugar. The specific gravity was 1.030. The temperature on the night of

admission was 102.5°. The next day it ranged from 100° to 101° and then gradually fell to normal. On the afternoon of the 23d, it again rose to 100°. The pulse ranged from 120 to 160 and generally from 132 to 140. The respirations ranged from 44 to 56.

To sum up, here was a young and apparently intelligent young woman who said that she had been perfectly well until nine days before admission, and that four days before admission she had been taken with a severe chill and since had been in bed with fever, cough, pain in side, and expectoration. The physical signs on admission bore out her statement, and consisted of flatness on percussion over the left lung, increased vocal fremitus, bronchophony, and pectoriloquy, tubular breathing, and some subcrepitant rales at left base. At the autopsy there was found a thickened pleura, with about 250 cc. of pus, a fibroid lung, with bronchiectasis and old tuberculous foci in both lungs. There was probably just enough air-space above the small layer of pus to act as a resonator for the voice and breath-sounds transmitted through the dilated bronchus.

The question naturally arises, Is there any certain way in which a pleural exudate can be recognized? Evidently there is no pathognomonic sign. The only safe way is to examine for all the physical signs and not expect any one sign to have a fixed and definite value. The value of a particular sign must be determined with reference to the special case under study and in connection with all the other signs. Thus, flatness on percussion and greatly increased resistance indicate fluid in the pleural cavity rather than consolidation of the lung; but they are far more significant if the upper line of flatness follows the curves studied by Garland and Ellis; if there is change in the level of flatness on change of posture of the patient; if above the level of flatness anteriorly there is skodaic resonance; if there is displacement of organs, and if there is restricted or absent movement of the diaphragm on that side.

In the same way, diminished or absent vocal resonance and fremitus, and distant or absent breath-sounds, while very valuable and, indeed, almost constant signs of pleural effusion, can not be relied on exclusively. Confirmatory signs must be sought for, and in all doubtful cases the question decided by puncture with a sterile needle.

West says: "By percussing the chest in front with two coins and ausculting behind as for the bell sound, a pleural effusion will sometimes be found to transmit a clear, metallic sound (penny sound, *signe de sou*), quite unlike that heard through healthy or solid lung.

T. H. Kellack¹ says that if the left hand is used to palpate in front under the nipple, while the corresponding ribs, just posterior to their angles, are percussed sharply with the finger or pleximeter, much greater vibration will be felt when fluid is present.

The most important test of the presence of fluid in the pleural cavity is puncture with an aspirating needle. The large syringe and needle used for antitoxin injections are preferable, because if the fluid is thick, it may not flow through the small needle of an ordinary hypodermic case, or the latter needle may not reach far enough. In spite of such precautions, however, fluid may be present and not be reached. In small, old empyemas the amount of pus may be small and not be reached unless the puncture be made lower than the sixth or seventh interspace, in which case there is danger of puncturing the diaphragm or liver. Or the needle

¹ *Lancet*, London, 1896, 1, p. 4-5.

may be thrust into a fibroid lung and a dry tap result. Or the pus may lie between the lobes and be difficult to reach. Sometimes a number of punctures has to be made before the pus is struck.

On the other hand, pus may be obtained from a sub-phrenic abscess, from the pericardium or from a dilated bronchus or lung-cavity.

The x-rays are of great service in the diagnosis of pleural effusion, and of the amount of fluid present. Williams says that when the effusion is large no more rays pass through it than through the liver and the outlines of the diaphragm, ribs and heart are obliterated on the side of the effusion. If there is a smaller amount of fluid, the outlines of some of the upper ribs are seen, and with a small effusion the outlines low down in the thorax only are ill-defined. The fluoroscope detects displacement of organs which may not be discovered by percussion, and so helps to distinguish between pleural effusion and thickened pleura. The upper line of the shadow may be made to move by shaking the patient.

A DIGEST OF 200 CASES OF PNEUMONIA.¹

By C. Z. WEBER, M.D.,

of Norristown, Pa.

As I am not presuming to pose as an *authority* upon this subject, but merely as a student and colaborer in the art of healing, I beg patient consideration of my effort, to digest in a somewhat statistical manner, as thoroughly as time will permit, the cases which have come under my observation during 18 years of practice.

Geographically, in our location, lying sufficiently adjacent to the sea-coast to be influenced by the damp, heavy winds of the ocean and alike by the abrupt changes in the air-currents moving north and south—two potent factors in the etiology of pneumonia—the prevalence of the disorder is naturally to be expected. Different years vary in the number of cases furnished, according as climatic influences vary. The least number of cases met in a single calendar year was 4, the largest number 25; average for the 18 years 11 and a fraction. The mortality varies also in different years—in 10 of the 18 years there were no deaths. In the 8 years in which deaths occurred, the smallest number was 1, the largest 4. In all, 18 deaths occurred, or an average of 1 per year.

Climatic changes play an important part in the mortality, though less than epidemic influences, such as la grippe. Comparing calendar years the mortality ranges from 100% of recoveries to 25% of deaths.

As different years vary in number of cases furnished, so do even more prominently the months.

January furnished 35 cases	July.....furnished 4 cases.
February " 33 "	August " 8 "
March " 26 "	September " 1 "
April " 27 "	October " 3 "
May " 13 "	November " 9 "
June " 4 "	December " 37 "

Taken by seasons the winter months furnished 105 cases, or 52.50% of the total number; the spring months 66, or 33%; the summer months 16 cases, or 8%; the autumn 13 cases, or 6.5% of the total number.

In reviewing the number of cases two other distinctive features were observed: The frequency with which

certain individuals are attacked, and the marked susceptibility of certain families to the malady. Under the first heading 13 individuals suffered at different times 31 separate attacks at intervals of from 3 months to 17 years. One individual suffered 5 different attacks during 15 years; 2 others each 3 at varying intervals, the 10 remaining each had 2 attacks, after longer or shorter periods. Contrary to expectation, here the deaths occurred not in any of the 3 who suffered the greatest number of attacks, but they occurred, 3 in number, from the list of 10 who suffered the second attack. Again, comparing the number of deaths in this class with the number of attacks, the mortality is 93½% or increased only by 3½%, as we shall find further on.

Under the second heading we find 26 families have contributed 69 cases, or 34.5% of the entire number.

One family alone contributed	6 cases.
Two families each " 5; total 10 "	
Two " " " 4; " 8 "	
Three " " " 3; " 9 "	
Eighteen " " " 2; " 36 "	

A study of these multiple cases in families demonstrates conclusively a transmitted susceptibility as a legacy from parent to child, and, also, in the instances in which both husband and wife were afflicted coincidentally with the children, the also indisputable fact that miasmatic, unsanitary and faulty hygienic influences play an important role in causing the disease.

DIFFERENT FORMS AND FREQUENCY.

The disease has been observed in the following forms: Croupous, catarrhal, interstitial, and bilious.

Croupous form contributed 63 cases or 21½% of total number.	
Catarrhal " 131 " " 65½% of " "	
Interstitial " 4 " " 2% of " "	
Bilious " 2 " " 1% of " "	

In 116 cases, or 58%, the disease was right-sided.	
In 70 " " 35% " " " left-sided.	
In 14 " " 7% " " " double.	

Croupous form was left-sided.....	40 times.
" " right-sided.....	23 "
Catarrhal " left-sided.....	47 "
" " right-sided.....	76 "
Interstitial " left-sided.....	3 "
" " right-sided.....	1 "
Bilious " double-sided.....	2 "
Catarrhal " double-sided.....	14 "
Catarrhal and croupous forms were combined	4 "

COMPLICATIONS.

Pneumonia was found coexisting with other diseases in one-half of the entire number of cases, or 100 times, as follows:

La grippe.....	40 times.
Phthisis.....	13 "
Measles.....	8 "
Valvular disease of heart.....	8 "
Whooping-cough.....	6 "
Bright's disease.....	5 "
Cerebrospinal meningitis.....	5 "
Pleuritis.....	5 "
Typhoid fever.....	4 "
Cerebral meningitis.....	2 "
Remittent fever.....	2 "
Bronchial asthma.....	2 "

Total..... 100

In combined forms there were 18 deaths, or 9%	
In complicated " " " 11 " " 11%	
In uncomplicated " " " 7 " " 7%	

¹ Prepared by appointment and read at the meeting of the Montgomery County Medical Society, March 14, 1900.

As the general mortality was represented by 9%, the uncomplicated by 7%, and the complicated shows but 11%, it would seem that complications detract very slightly, or but 2%, from the general mortality percentage. Upon the other hand, when the whole number of deaths is compared with the fatal complicated cases, it is seen that 6.2% of the deaths are chargeable to the complications. Of the double forms, 14 cases, including those in complicated and uncomplicated forms, 10 were fatal or 71.4%.

In the number of fatal cases, age plays a conspicuous part—the extremes of life furnish almost the entire number of fatalities. Thus 7 deaths occur prior to 10 years of age, 1 case from the tenth to the twentieth, none between the twentieth and thirtieth, none between the thirtieth and fortieth, none between the fortieth and fiftieth; 2 occur between the fiftieth and sixtieth, 3 between the sixtieth and seventieth, 3 between the seventieth and eightieth, 1 between the eightieth and ninetieth, and 1 in the ninety-second year.

If we divide life into three periods of 25 years each, the first or early period furnished 8, or 44.4%, of the deaths; the middle period, that between 25 and 50, furnished 2, or 11.1%; and the late period, that from 50 years upward, furnished 8, or 44.4%, the same as the early period.

In reviewing the list of cases, I am reminded of a class comprising 6 cases, which I will classify as "walking cases." They were observed in both the croupous and catarrhal form, there being three of each. The following histories may prove interesting:

1. A. F., aged 27, weaver, sought office treatment for pain in side and general weakness. Upon careful examination of chest, the middle lobe of the right lung was found to be hepatized.

2. W. H., aged 30, merchant, sought office treatment for what he described as lumbago. He complained of general malaise, but was free from cough. Examination revealed solidified left lower lobe.

3. Boy, aged 7, attending school, summoned me because the family feared he was suffering from mental disorder. Examination disclosed right-sided catarrhal pneumonia, apex hepatized, which accounted for the mental perturbation, walking in sleep and other irrational phenomena observed.

4. H. R., clerk, aged 23, complained of shortness of breath and reported at office, being suspicious of heart-trouble. There was no cough, except an infrequent, nervous hack. He had been ailing for upwards of 10 days. While investigating the cardiac region, a solidified lower left lobe was discovered.

5. L. F., butcher, received office advice and examination, concerning a fissure in ano. There were no visible, objective symptoms, indicative of organic trouble, so far as could be ascertained except those referable to the fissure. Dilation under anesthesia was arranged for the following afternoon. He slaughtered cattle in the forenoon, suffering no unusual inconvenience. Chloroform was administered, the operation performed, when it was accidentally discovered that he had been carrying about a hepatized lower left lobe.

6. School-boy, aged 7, was sent from school by teacher because he looked tired and inanimate, and exhibited symptoms of fever, associated with severe cough. A chill occurred Saturday. He attended Sunday school on Sunday, and public school on Monday and until Tuesday noon. Upon auscultating the thorax the fourth day after the initial chill I discovered a solidified left lobe.

These cases were taken in hand, placed in bed and after a more or less protracted period, they all recovered.

In striking contrast with the rational management of this class of cases, it may be interesting to note the history of the following case:

Male, age 34, had been 12 days ill with croupous pneumonia in the left lower lobe. We had just taken up the alternative

plan of treatment, when the patient abruptly refused to be further restrained or yet to continue treatment, and against the earnest protestations of both family and physician returned to his work, that of a tailor. He had been a confirmed, steady drinker. With the resumption of work, he also resumed his former habits. Singular to state, after a lapse of two months, visiting another member of the family, I utilized the opportunity to examine his thorax, when, to my surprise, I found as good a vesicular murmur as on the opposite side, every evidence of the trouble having disappeared. The original attack occurred in February, 1894, and he has enjoyed unimpaired health since.

As already stated, interstitial pneumonia appeared *left-sided* in 75% of cases. The only right-sided case met, occurred in a severe case of croupous pneumonia, immediately following an attack of la grippe.

In this case a vigorous man was much reduced in strength and 2 months after the original attack, while at a Southern health resort, contracted a severe cold, when interstitial pneumonia set in. After the lapse of a fortnight, an abscess occupying the position of the whole middle lobe, developed. This victim vomited and expectorated pus by the pint. After the acute symptoms subsided and the patient spent a year in a Southern climate, his health was completely restored. Two years after this occurrence, the subject passed a critical examination for life insurance, every vestige of the disorder having entirely disappeared. It is now five years since the attack, his health remains good, nor does he suffer from catarrhal affections more than formerly.

In the only interstitial case that proved fatal, after the patient survived the acute symptoms, a direct hereditary phthisical predisposition carried him into rapid consumption, to which he succumbed six months later. Of the two remaining interstitial cases, one patient has lived 17 years since the abscess discharged, after having for a period of three years exhibited symptoms of tuberculous trouble in both lungs and throat, the trouble in this location not yielding until the vocal cords were hopelessly destroyed. Her health at present, while not good, is such that she is able to assist in the maintenance of a large family by sewing and performing other light duties in the home.

The remaining patient has lived three years since the discharge of the abscess and has now fully regained her lost vitality. The first year following her convalescence, the rigor of our winter was shunned by living South and the depressing heat of our summer was avoided by sojourning North.

The cases of bilious pneumonia occurred at the same time in brothers. They occurred in the early part of November, while the family were having sewer connections and building operations under way. These boys, characteristic of their age, were much in the trenches and excavations incident to the improvements, so it would seem that this unsanitary state of the premises was the exciting cause. They both exhibited symptoms of catarrhal pneumonia and catarrhal jaundice. They were both actively delirious, which symptom does not attach to catarrhal jaundice; and again, they were both much jaundiced, which does not attach to pneumonia. It was interesting, again, to observe the depressing effect of the jaundice on the morning temperature and also the effect of the hyperpyrexia of the evenings in increasing the irritability of the stomach, and all the while the areas of bronchial breathing were unchanged by the misleading morning remission of the temperature.

Before taking up treatment, a few general observations would seem to be warranted by a review of these records.

1. The most frequent predisposing cause of inflam-

ination of the lungs is some preexisting disease. In fact, idiopathic pneumonia may be attributed entirely to depressing influences. Given susceptibility, pre-existing disease, or even an individual in whom for any cause functional activity is out of balance with constructive metamorphoses, and add abrupt temperature-changes, with or without exposure, and the resulting combination is readily pulmonary inflammation.

2. Pulmonary inflammations are not only more prevalent in periods, comprising sometimes several consecutive years, but the *type* is also more virulent. Take for example the years of 1897 and 1898, in which extremes of temperature sawawed abnormally throughout. These 2 years contributed 44 cases, or 22% of the total number under consideration. During this period there were 7 deaths, yielding a death-rate of 15 $\frac{1}{11}$ %, or 61 $\frac{1}{11}$ % above the general average. With this period we would contrast the 2 years next preceding, throughout which more normal weather conditions prevailed and in which but 14 cases were met with, recoveries, 100%.

3. La grippe, since its advent in this country during the winter of 1897, has not only augmented largely the number of cases, but has increased also our mortality. As previously shown, this affection alone has contributed 20% of the total number of cases. Prior to the prevalence of la grippe, 56 cases were treated from 1883 to December of 1889, with 2 deaths, or a mortality of 3 $\frac{1}{2}$ %. Subsequently to December, 1889, while la grippe has been more or less a factor in the etiology, 144 cases have contributed 16 deaths, or a mortality of 11 $\frac{1}{12}$ %. In the period embraced by the years 1897 and 1898, just alluded to, 5 of the 7 deaths in the 44 cases, la grippe was present, and 3 of the 5 were in children who succumbed in the early stage of the catarrhal pneumonia coexisting.

4. Left-sided croupous pneumonias have proved more difficult to manage and have contributed more frequently to the class of cases in which the croupous condition merged into that of phthisis.

5. Catarrhal pneumonias, when the apexes of the lungs are involved, are always associated with delirium. Case in illustration:

W. H. was suffering from profuse metrorrhagia, having missed two menstrual periods. She was ordered to bed and a nurse placed in charge. On the second day the nurse complained that she could not induce the woman to remain in bed. I had never known the woman to be untruthful, but when I urged her strictly to obey orders, she denied point blank having been either disobedient or incorrigible. On the evening of this day, I made a second visit, when all doubts as to the charges of the nurse and the denial of the woman were removed by meeting the patient in the vestibule, bare-footed, clad in her night dress, and holding a lighted lamp in her hand. She addressed me by her husband's first name. Immediately seizing the lamp, I made an impromptu diagnosis of *acute mania complicating miscarriage*. Upon going more thoroughly into the case, having got the patient back to bed with the aid of the nurse, now upon the scene, I found a temperature of 103°+, which was scarcely accounted for by the threatened miscarriage, and associated with it was found a hepatized right apex. So, a diagnosis of pneumonia complicating miscarriage was substituted for the one made a few minutes before in the vestibule, and the doubt as to the sanity of the woman and the ability and veracity of the nurse was cleared up. The delirium was here found to be of a spasmodic type.

It is due the credit of the nurse to explain that, under the circumstances, the patient's escape from her vigilance was pardonable. She had stepped into an adjoining room for a glass of water at the patient's request. At this instant the door-bell rang and quick as a flash

the patient sprang from the bed, grasped the lamp from the table on her way to the upper hall, descended the stairs, traversed the lower hallway, and appeared at the front door as described.

6. Alcoholism and typhoid fever do not chance to enter as a factor in our mortality, but both have been observed to retard the stage of resolution and otherwise lengthen the period of convalescence.

Upon the subject of the treatment of pneumonia, volumes have been written. That there is little conclusive evidence in support of the germ-theory, is certainly apparent. Nor is it essential that we recognize a specific *materies morbi* in the etiology of the disorder. So long as we can comprehend cerebritis, splenitis, hepatitis, nephritis, endocarditis, meningitis, synovitis, and pleuritis, developing without specific cause, so long will we be able to cope with pneumonitis in disregard of tangible cause.

Of the various causes ventured as an excitant of the disease, I would prefer the nervous theory. In tests of the textile strength of metals there is an old maxim "That no chain is stronger than its weakest link." So every individual may be regarded as having a weakest link—an organ, for instance, which gives way at point offering the least resistance. There is, naturally, this point of difference, however, though the analogy is not less striking—that with animate structures the point of resistance may shift from organ to organ, according as seasons, heredity, age, environment and climatic conditions may elect.

Given, therefore, an exciting cause, the respiratory organ by virtue of some more or less established, depressing influence, the most vulnerable part of the physical anatomy, the result is rationally an inflammation of the lung. To serve the purposes of this paper, however, our treatment is based upon the idea that we are dealing with an organic, inflammatory affection.

To be brief, our armamentarium for first stage,—that of general malaise and congestion—is made up of counterirritants, arterial sedatives, antipyretics and anodynes. I am confident I have seen cases of incipient pneumonia nipped in the bud by the timely employment of sinapisms over sensitive pulmonary areas, together with the administration of aconite, acetanilid or veratrum viride and also by the mixed arterial sedative and anodyne formula of morphia sulfate and antimony.

In no affection is it more important than in pneumonia to treat conditions more than the disease itself. In other words, we need to be more mindful of the patient than his disease.

In the second stage, that of infiltration and hepatization, it is well to bear in mind the old saying "That things are seldom so bad but they may become worse" and vigorously but cautiously employ arterial sedatives, antipyretics and even the counterirritants, with the view of limiting the area of infiltration and hepatization so far as possible. In my experience it is usually in this stage that a physician's services are first enlisted. It is at this stage when the progress of the case in hand has been arrested or held in abeyance that the carbonate and iodid of ammonium are especially indicated, while only sufficient of the antipyretic, as, for instance, sodium salicylate is employed to keep the temperature well in hand. I seldom find it advantageous to combine opium with the prescriptions regularly employed. Opium in the form of dover powder is best given alone when indicated. As we approach the stage of resolu-

tion or what might be termed miliary purulent suppuration, serpentaria in the form of the fluid extract, combined with ammonium carbonate and liquor ammonia acetatis, is found to be of great advantage.

Venesection was employed in two cases. In the first case there was marked cerebral congestion which was relieved by the bleeding, but there was observed no appreciable effect upon the hepatization. In the second case, the blood-letting, at the beginning of an extensive hepatization, was followed by a long and tedious convalescence complicated by bedsores. Cups, both wet and dry, applied to relieve pleuritic stitches during the early active, inflammatory process, were found decidedly helpful.

It is in the third stage that the patient's chances are fraught with the greatest danger. We have here to combat exhausting vital force, pulmonary structure loaded with debris, hereditary influences, and complications adding to the gravity of the situation; in short, a crippled train on a wrecked roadbed to get back on schedule time with the surest means of safety and the least possible delay. It is here that antipyretics are discontinued, alteratives are brought forward, such as corrosive sublimate and iron, the iodid or carbonate of ammonium, administered in increased doses. Strychnin sulfate is perhaps employed, or, if the case has been complicated with la grippe, it has been used from the beginning of the second stage. If resolution is delayed or tardy, tincture of iodin and cantharidal plasters are employed to vesicate the surface and hasten absorption. I have observed a rapid solution and absorption, in some cases, of the products of inflammation by a copious, artificial night-sweat, induced by a full dose of jaborandi or an hypodermic injection of pilocarpin.

The affected lung once restored to its normal condition, or frequently pending such termination, I have found the official formula of the compound syrup of the hypophosphites to be eminently serviceable in favoring general reconstructive metamorphosis.

PYLORECTOMY FOR ADENOCARCINOMA. WITH REPORT OF A CASE.

By JOS. H. BRANHAM, M.D.,

of Baltimore, Md.

Professor of Surgery and Abdominal Surgery, Maryland Medical College.

J. R., white, male, came under my charge about September 1, 1899. His family history was good, no cases of malignant disease being noted. His general health had been good until about 18 months before, when he had a severe attack of malaria. This was followed by recurrent gastric attacks characterized by cramps and vomiting, the vomit containing bile. During this time he had to be careful as to food, coarse articles causing distress and a sense of distention in the upper region of the abdomen.

Examination.—The patient is tall and spare; skin sallow and muddy, pulse weak and rapid on exertion, mucous membranes pale. Physical examination of abdomen shows thin walls, tenderness over region of stomach, which organ was slightly dilated, and the spleen much enlarged. Under large doses of quinia the splenic enlargement rapidly disappeared, but the gastric symptoms grew worse. Gastric lavage gave little relief. September 26 he was admitted to the National Temperance Hospital and shortly afterward Prof. C. Urban Smith was able to make out a small mass at the right of the median line above the umbilicus. This could only be felt when the patient sat with his legs well apart and stooped well forward.

The following notes by Prof. Smith elucidate the points of

diagnosis: Contents of stomach, acid; hydrochloric acid, .09%; free lactic acid; free butyric acid. Pepsin and rennet normal; excess of mucus; yeast-cells and a few cells resembling cancer; the salol-test showed good motor functions. Potassium-iodid test showed delayed absorption; indican was found in the urine. Diagnosis, cancer of pylorus.

Preparation for Operation.—The patient was put on a strictly liquid diet and for two days was given 3 grains of salol and $\frac{1}{10}$ grain of strychnin nitrate three times per day. The night before he was given a purge and immediately before taking the anesthetic his stomach was carefully washed out with sterile salt-solution. The usual preparations of the parts to secure surgical cleanliness were made.

Operation was done on October 12. A median incision about four inches in length enabled us to examine the organs in situ. The pylorus was slightly lower than normal and was freely movable. A small growth about two inches in length and an inch broad was found occupying the anterior and inferior aspect of the pylorus, encroaching on the duodenum. Its length corresponded to the circumference of the gut. This growth extended about two-thirds around the organ, and was firm but not very hard. No other abnormality was found in the neighboring parts. The attachments of the omentum to this part of the organ were tied off and severed. The diseased part was now drawn well forward into the abdominal wound and surrounded by sterile gauze sponges. The attachments were divided and the duodenum severed about an inch below the neoplasm and the stomach the same distance above. An end-to-end anastomosis was next made by means of a Murphy button which was reinforced by peritoneal sutures. The abdominal wound was closed after carefully cleansing the parts with salt-solution, part of which was left in the peritoneal cavity. All the sutures used were catgut hardened in a solution of mercuric chlorid in alcohol 1 to 1000.

The patient was very weak and had several subcutaneous infusions of salt-solution during the first 24 hours after the operation. He was also given about $\frac{1}{10}$ grain of strychnin nitrate during and after the operation. He rallied slowly. For the first 5 days he had nothing by the stomach, being nourished entirely by the rectum. On the 14th he had his highest temperature, 101°. He was allowed to wash his mouth with cold water.

On the 17th he was given small quantities of albumen and panopeptone. This collected in his stomach and caused great distress, and was washed out on the 19th by the stomach-tube. This procedure gave great relief and was continued about every second day for two weeks. As little of the food taken by stomach was absorbed, the rectal feeding was continued during this period. On the 30th, 18 days after the operation, the Murphy button was removed from his rectum by the resident physician. He gradually became able to digest food, and gained strength slowly. His temperature was nearly always subnormal, both before and after the operation; this I attributed to the bad nutrition due to insufficient assimilation.

He left the hospital November 20th, and returned to his home in North Carolina, weighing at this time about 84 pounds. He reported by letter from time to time to me and gradually gained strength and weight until April, 1900, he had reached the very respectable figure of 147 pounds.

Pathological Report.—Prof. R. L. McNeer. "The growth is a carcinoma, showing at points sufficient glandular arrangement to justify the name adenocarcinoma. Beside the principal mass a number of small points of invasion of the surrounding tissue is noted. The growth seems to have encroached on the mucous membrane of the duodenum to a great extent."

General Considerations.—The recent great improvement in operative technic and in means of diagnosis giving better results, have aroused much interest in the surgical treatment of disease of the stomach. Pylorectomy was first done in man by Pean in 1879, and the first successful case was by Billroth, 1881. The mortality was high in the early cases, but recently it has been much diminished. The following table is probably not nearly complete, but will give a general idea of the mortality, and also of the improved results of recent operations.

	CASES.	RECOVERED.	DIED.
¹ Winslow	60	16	44
² Mikulicz	32	8	24
Billroth	19	8	11
Guinard	299	194	105
Czerny	29	18	11
Kronlein	24	19	5
Carle	14	11	3
Mikulicz	20	15	5
Hartmann	10	6	4
Wilmot ³ , Evans....	13	12	1
Morison	5	5	0
Kocher	57	50	7
Maydl	25	21	4
Roux	12	9	3
Tuffier	9	6	3
Lambotte	5	4	1
Van Kleff	4	1	3
Leeds Infir'y Staff	7	3	4
Karg	4	4	0
Gussenbauer	13	7	6
Mayo	3	3	0

Referring to the above table we find that the cases collected by Winslow and Mikulicz (1 and 11) were the early cases done before 1885. They are probably duplicated to an extent, but as they give almost the same results, this does not impair their value for comparison. Taken together they show a mortality of 74%. The rest of the table, taken from an article by Mayo Robson,³ which shows the combined mortality of both the old and new cases, shows 572 cases; recovered 398, deaths 174, mortality 30.4%. Could the old cases be eliminated, this mortality would be much further reduced. The remarkable result shown by Kocher, 57 cases with a mortality of less than 9%, gives hope that we will soon be able to class this as one of the operations not excessively dangerous.

The remote results of the operation unfortunately have not been so good, most of the cases being relieved for only a short time, and later showing recurrences. The 50 successes of Kocher show one woman living 10 years without recurrence, one 5 years, one 3 years, and one 2 years. Four died of other troubles without recurrences after 3 or more years, so we may claim these 8 cases as permanent cures out of the 57 cases operated on. The other cases of the 52 who survived the operation were made more comfortable and in the aggregate had many years of useful life added to their existence.

Unfortunately we are still in the dark as regards the etiology of malignant disease. True, much recent work has been done along this line and reports have been made. This will no doubt be of great value in the future; as yet, however, we have nothing accepted by the profession as proved. We have good reason to hope that we shall soon have light on the cause of this terrible scourge, and that this may lead to improved methods of treatment.

Great advance has been made along the line of diagnosis. Some points in the natural history of the disease will assist in reaching a correct conclusion. Cancer occurs usually after middle life, but there are many exceptions to this rule. A paper by Prof. William Osler and Dr. McCrae gives the proportion under 30 years in a collected table of 3,257 cases as 2.5%. In 150 cases from the Johns Hopkins Hospital 4% were under 30. Men are more often the subject of gastric cancer

than women. The position of the growth is most frequently the pylorus, over 60% of cases being found here. Among the symptoms pointing to this disease we note briefly pain, dull, often continuous, and increased after eating; belching of gases, often foul; vomiting of partly digested food, later, mixed with decomposed blood (coffee-grounds); loss of weight and energy; temperature not infrequently subnormal, but may be elevated in rapid cases near the end. There is usually some dilation of stomach when the growth is at the pylorus. The presence of a mass can usually be determined by examining patient frequently and in various positions. The value of change of position was well illustrated in my case. The stomach should be examined empty, and distended both by gas and fluid. Great assistance may be obtained by careful examination of the contents of the organ. Absence of HCl, while not a positive sign, points strongly to the existence of cancer. Excess of lactic acid is suggestive of cancer: the finding of parts of the growth in the wash-water may enable a positive diagnosis: unfortunately, this is possible only late in the disease, and often after the time for radical operation has passed. The x-ray may outline the mass. Finally, the exploratory incision should be relied on more frequently; such procedure should be considered as almost harmless, as it is in other parts of the abdomen, and should be employed early, as soon as there is strong suspicion of cancer; this will enable the surgeon to attack the growth while it is still small.

When a neoplasm is found after opening the abdomen the selection of the proper operation for the case is of great importance. If the lymphatic glands are involved and many adhesions are present the operation should be abandoned, or in case there are symptoms of stenosis present a gastroenterostomy should be done. Pylorectomy is indicated when the growth is in the pylorus, and when the glands are free and the organ not much adherent. Partial or complete gastrectomy is to be done when the tumor occupies other situations and the organ is free from adhesions. When adhesions are present the operation becomes excessively dangerous, and even when successful recurrence soon takes place.

The method of operating differs much with surgeons. Kocher first does a gastrojejunostomy, and some weeks later excises the mass, closing the two cut ends of gut. He has had better results than any other surgeon who has had a very large number of cases. He does not like the Murphy button, as he says it often fails to pass, and he reports one case in which it was found in the stomach 14 months after the operation. Dr. Mayo, of Rochester, Minn., who has had five successful cases and no failures, always uses the button. Its advantages are the ease and rapidity with which it enables closure of the bowel. The slough which it causes is probably advantageous, as it removes tissue which is near the growth and is possibly infiltrated. It is not necessary to draw on the organ to so great an extent when it is used, thus dragging on the nerves; other important parts are avoided, which, together with the saving of time, lessens the shock and the other bad results of long exposure and manipulation of the parts.

The case reported illustrates some important principles. The marvelous improvement in the patient's general condition and the small extent and slow growth of the tumor lead us to hope that this will be one of permanent cure. The repeated washing out of his stomach after the operation relieved the patient of great distress and probably saved his life. Too many physi-

cians and surgeons tend to despair of the unfortunates who are attacked by this dread disease. Many, like Micawber, are waiting for something to turn up from the laboratory workers. That some other means of destroying or preventing cancer may be discovered we all hope, but it would be the height of folly to fold our arms and wait for such a consummation; better try to improve known methods of attack. Nothing will help us so much in this direction as early diagnosis and operation. Much is due to the stomach specialist in helping to perfect means of diagnosis; but often he treats these cases until the disease has advanced too far. Careful lavage and diet not infrequently lead to temporary improvement; both physician and patient are soothed into a fatal sense of false hope, and procrastinate until the time for radical operation has passed. The exploratory operation will probably do more to save these poor unfortunates than anything else, and should be more frequently employed. Practically all these cases are operable at some period of their existence, and we have reason to hope that in the future they will be referred to the surgeon at a time when the tumor can be successfully attacked, and not only temporary relief be possible, but when a large proportion can be permanently cured. The cases of absolute cure of cancer in other organs are becoming more and more common; surely we can hope for this same advance in cancer of the stomach in which glandular involvement comes late in the disease.

INHIBITION OF THE HEART AS AN AID IN DIAGNOSIS.*

By ALBERT ABRAMS, A.M., M.D.,

of San Francisco.

Consulting Physician to the Mount Zion Hospital and the French Hospital.

PHYSIOLOGISTS have taught us that the inhibitory nerve of the heart is the vagus, stimulation of which stops the heart in diastole. Stimulation of the sympathetic cardiac nerves has exactly the reverse effect, causing increase in force or rate of the heart-beats; these are the augmentor and accelerator nerves. The latter are less easily tired than the vagus fibers; thus, if the vagosympathetic of the frog is stimulated, the first effect is inhibition, due to vagus action; the vagus fibers then tiring, the effect of stimulation of the accelerator fibers become evident and the heart commences to beat more forcibly and rapidly than before. If the cardioinhibitory center in the medulla is stimulated, inhibition of the heart ensues. The afferent nerves from the abdomen and intestine are in close communication with the center, so that reflex inhibition of the heart can easily be produced in the frog by tapping a loop of the intestine with the handle of a scalpel. Severe abdominal affections, like peritonitis and appendicitis, are frequently attended with symptoms of heart-collapse, owing, no doubt, to reflex inhibition of the heart. Morphin and digitalin slow the heart-movements by stimulation of the cardioinhibitory center. Muscarin and physostigmin inhibit the heart by stimulating the nerve-endings of the vagus. The slowing of the heart is probably carried out by the afferent impulses ascending the vagi from the heart to the cardioinhibitory center, from which inhibitory impulses are sent down

the vagi. Czermak was able to press his vagus nerve against a little bony tumor in the neck, and by thus subjecting the nerve to mechanical stimulation was able to slow or even to stop the beating of his own heart. This was the first demonstration in a healthy person of facts already known to the physiologist. If, in a healthy person, the carotid artery, or a point immediately adjacent to it in the neck, is compressed, as a rule, slowing or complete inhibition of the heart-action and pulse ensues. The latter may be made to disappear for fully 75 seconds; with prolongation of the pressure, the cardiac function is resumed. Such pressure often induces in the patient experimented on symptoms of vertigo, and even syncope. Many of my patients on whom this maneuver was attempted suffered from precordial pain—in fact, it was always found to be extremely painful. (Quincke explained the phenomenon by attributing it to pressure of the vagus lying alongside of the carotid artery. He discountenanced the theory that the cardiac phenomenon was due to compression of the carotid artery and cervical veins, with consequent circulatory disturbances in the brain.) The phenomenon is best observed in thin and long-necked persons, in whom the vagus is most easily and conveniently reached.

Sometimes the phenomenon is only observed after pressure is made on both vagi, whereas in other instances cardiac inhibition is attained after pressure is made on one vagus, which, experience has taught, is usually the right vagus. The investigations of Wasylewsky show that the irritability of the vagus is frequently increased in the sick and among convalescents. Intermittency of the heart is a condition in which the heart-movements may be inhibited for several seconds. Heart-intermittency is differentiated from simple irregularity of the heart-movements by the fact that in resumption of the cardiac contractions they are regular from the beginning. Many persons can voluntarily produce intermittency of the heart, and among Indian sorcerers the phenomenon is regarded as a marvelous feat. Donders was the first to solve the riddle, which he explained as follows: By voluntary contraction of the neck-muscles, innervated by the nervus accessorius, the branches of the latter running in the vagus-path were irritated, resulting in temporary stoppage of the heart-action. What I have denominated the *heart-reflex*¹ is yet another means of momentarily inhibiting the cardiac action, although less markedly than by the methods previously cited. If we irritate the skin in the precordial region, a contraction of the myocardium is thereby reflexly induced. Receding from the precordial region, irritation of the skin will proportionately diminish the myocardial contraction.

These facts are not demonstrable by percussion because the same stimulus results in the production of the *lung reflex*, which in itself is an acute lung dilation, thus making percussion for the superficial area of cardiac dulness elusive. The phenomenon of myocardial contraction (*heart reflex*), is only manifest by means of the Röntgen-rays and the fluoroscope. The heart-contraction is sudden and of momentary duration and, like other reflex acts, soon becomes exhausted. By whatever method heart-inhibition is attempted, the pulse should not be selected as a guide. The paradoxical pulse has lost much of its clinical significance as a diagnostic aid in mediastinopericarditis, since observa-

* Read before the annual meeting of the Medical Society of the State of California, April 17, 1900.

¹ Transactions of the Medical Society of the State of California, and the PHILADELPHIA MEDICAL JOURNAL, January 6, 1900.

tion has shown that in health distinct respiratory changes in the pulse are demonstrable by means of the sphygmograph. The sphygmogram shows a fall in the pulse-curve during inspiration and a rise during expiration. Sommerbrodt has shown that by means of his sphygmograph, many healthy persons can, during inspiration, extinguish the pulse. Knoll suggests, however, that by this maneuver we must guard ourselves against a possible error. If the person from whom the sphygmogram is obtained inclines toward the radial artery from which the tracing is secured, then, and then only, does forced inspiration obliterate the pulse, which is not observed when the recumbent posture is maintained. Knoll inclined toward the belief that the cause of the phenomenon observed by Sommerbrodt is really due to the enlarged thorax pressing on the axillary artery. Mere elevation of the arm, as I have already shown,² will cause the radial pulse to become less and less evident, until, when the arm has attained the vertical position, the pulse in some persons is no longer palpable. The foregoing facts demonstrate that by direct auscultation of the heart only are we able to take cognizance of heart-inhibition. Prof. Sewall, of Denver,³ has investigated cardiac murmurs under increased pressure of the stethoscope. He found that murmurs of aortic stenosis audible at the apex disappear under pressure there, and are herein distinct from mitral regurgitation. Also, that in great dilation of the aorta,

diagnosis. For clinical purposes, inhibition of the heart, according to my experience, is best attained by voluntary contraction of the muscles of the neck, which, however, must be forcible to effect the purpose. It is a maneuver readily learned, even in children, and, once mastered, any person is capable of temporarily restricting the heart-movements. If undue exertion is used in contracting the muscles of the neck, the reverse effect is induced, viz., acceleration of the heart-movements. In a few instances, I have found that if the patient draws the head backward slowly, though forcibly, the hypertension of the cervical muscles is more effective in inhibiting the action of the heart than the maneuvers previously described. There are many persons to whom no instruction is intelligible, and with such individuals I place a long, narrow cushion on the anterior surface of the neck and ask them to press with all their might on the cushion with their chin. Many of my colleagues who attempt to employ this method will at first be disappointed with the results, but gradually they will learn to eliminate those adventitious factors so necessary for success in the employment of any new method. They will also find disappointment in the fact that the heart-movements are not inhibited nor the heart-pulsations decreased. It is seldom that we are able to stop the heart-action. What we do accomplish is the inhibition of the intensity of the heart-tones and here lies the real value of this method in

the murmurs of aortic regurgitation may be annulled by pressure at the base, but not at the apex. Inorganic murmurs at the base, he maintains, may all be obliterated by pressure. Friedreich⁴ was the first to direct attention to the stethoscopic phenomena observed by Sewall. The general observation was made by Friedreich that pressure on the chest would often cause murmurs to disappear. My own results with the method suggested by the latter investigator confirm what he has already observed, viz., that it is usually only in the young with elastic thoraxes that the stethoscopic phenomenon is of value.

Friedreich was of the opinion that the disappearance of cardiac murmurs by pressure with the stethoscope on the thorax was caused by mechanic interference with the cardiac movements. Studying the phenomenon under the x rays, my own conclusion is that the theory of Friedreich is wrong, that stethoscopic pressure is tantamount to any other cutaneous irritation in the precordial region, resulting in what I have called the heart-reflex, which in itself is myocardial contraction with momentary arrest of cardiac function. Having, as a rule, failed to get results with the stethoscopic method, I sought to secure the same results by other means. Indeed pressure with the stethoscope will, in not a few instances, intensify both organic and inorganic murmurs. Cardiac inhibition is of undoubted value in

diagnosis. Another fact will be noted, that while the patient is perfectly able to control the heart-movements on the first or second attempt, every succeeding attempt will diminish this power. This is in accordance with the well known physiologic fact, viz., that if in the frog we stimulate the vagosympathetic, the first effect is inhibition, due to vagus action; the vagus fibers then tiring, the effect of stimulation of the accelerator fibers becomes evident. Usually a few seconds elapse before the effect on the heart becomes manifest, then while the subject is still forcibly contracting the muscles of the neck, the cardiac tones become less and less evident, assuming an embryocardial character, until finally they are no longer audible. The accompanying sphygmogram was obtained from an individual on whom the method of heart-inhibition was tried for the first time.

The sphygmogram shows the pulse-tracing before and after cardiac inhibition. We note in the sphygmogram the almost total annihilation of the pulse-curve after vagus irritation. Now, with regard to the clinical application of this maneuver, let us recall a few facts relative to heart-murmurs. The site of a murmur is usually determined by noting its position of maximum intensity and the direction of its transmission. The loudness of a murmur indicates as a rule good compensation. Increase in the force of the heart-action will usually increase the intensity of a murmur; in fact, it is often necessary to elicit a faint murmur or augment its intensity by having the patient undergo some slight

² A new method of eliciting the subclavian murmur, the *Medical Standard*, October, 1899.

³ "System of Medicine," Albutt.

⁴ *Lehrbuch der physikalischen Untersuchungsmethoden*, 1881.

exertion, such as walking or breathing rapidly. Even loud murmurs may become weak or disappear in the course of febrile affections and in the moribund state owing to the slow and feeble action of the heart. It is the latter fact which is of special significance to us in the clinical application of the inhibition maneuver. The following essential facts may be summarized as a result of my investigations.

1. The inhibition maneuver will cause organic cardiac murmurs to become faint and in exceptional cases will render them inaudible.

2. Transmitted murmurs are more amenable to the maneuver.

3. The fainter the murmur, the more easily is it suppressed by the maneuver.

4. When a transmitted murmur can be inhibited, the tone which it masks can be auscultated.

5. Heart-tones are less amenable than are heart-murmurs to inhibition.

6. Hemic murmurs are more readily inhibited than are the organic murmurs.

7. As a rule, the murmurs of anemia may be suppressed and their evanescence is marked by the reappearance of tones.

8. Exocardial murmurs are easily influenced by the inhibition maneuver.

9. When the inhibition maneuver is incorrectly executed, the result is to increase the intensity of the murmurs owing to increased exertion which intensifies the force of the heart's action.

10. The inhibition maneuver when often repeated is futile in its results owing to overstimulation of the vagi.

11. In irregular action of the heart or in delirium cordis, the inhibition maneuver, by momentarily inhibiting the rapidly of the heart, renders signal service in determining the time of a murmur; the maneuver being practically in its effects like the physiologic action of digitalis on the heart.

12. The inhibition maneuver enables us to determine the condition of the vagi as inhibitors of the heart and guides us in the administration of cardiotonics.

Cardiac inhibition suggested itself as a therapeutic method to correct rapid and irregular action of the heart, but up to the time of writing it has rendered me little or no service. The following cases selected from practice, will serve to illustrate the real value of the inhibition maneuver.

CASE 1.—Murmur audible during diastole in the second right interspace. It is moderately loud. At the apex a systolic tone and a diastolic murmur are heard. During the inhibition maneuver, the murmur in the second right interspace becomes fainter while the diastolic murmur at the apex disappears and is replaced by a diastolic tone. Diagnosis: aortic incompetency. The diastolic murmur at the apex is a transmitted murmur.

CASE 2.—A loud murmur, audible during diastole, in the second right intercostal space. At the apex, systolic murmur and diastolic tone. Inhibition maneuver; murmurs over the aorta and apex persist, but are less loud. Diagnosis: aortic incompetency and mitral insufficiency. The systolic murmur at the apex is not transmitted, but is dependent on mitral incompetency.

CASE 3.—Systolic murmur at the apex which is transmitted to the axilla and back. In second left interspace, systolic murmur and diastolic tone. Inhibition maneuver; all the murmurs are inaudible. Systolic murmur at the apex is not supplanted by a tone. At the second left interspace, systolic murmur is replaced by a tone. Diagnosis: mitral insufficiency. The systolic murmur over the pulmonic ostium is a transmitted murmur.

CASE 4.—Systolic murmurs over all the ostia. They are not transmitted away from the heart. They are soft and blowing in character. Murmurs likewise heard in the jugular veins. Blood-evidence of oligocythemia and hemoglobinemia. Inhibition maneuver; systolic murmurs over all the ostia replaced by systolic tones. Diagnosis: murmurs of anemia.

CASE 5.—Murmur systolic and diastolic in time in the third interspace on either side of the sternum, modified by pressure with the stethoscope and position of the patient. Anemia not present as determined by the hemocytometer and hemoglobinometer. Inhibition maneuver; murmurs disappear and the cardiac tones become evident. Diagnosis: pericardial murmurs.

CASE 6.—Murmur heard loudest at the fourth left interspace. Heart very rapid and irregular in action. No anemia present nor physical signs of pericarditis. Inhibition maneuver; murmur disappears and tones systolic and diastolic heard over all the ostia. Diagnosis: cardiomyocardial murmur. An examination of the heart a week later when the heart-irritability was allayed by rest in bed and the use of digitalis, the foregoing diagnosis was confirmed.

CASE 7.—Cantering rhythm of the heart. A slight murmur is present. The time of the latter is impossible to determine. Inhibition maneuver; systolic and diastolic tones are clearly distinguished over all the orifices with the exception of the mitral orifice. At the latter orifice, only a diastolic tone is heard. Diagnosis: the murmur is evidently dependent on mitral incompetency.

HEMORRHOIDS: ETIOLOGY, PATHOLOGY, AND TREATMENT.

By J. WILLIAM J. DOYLE, M.D.,
of Philadelphia.

Clinical Assistant, Surgical Clinic, Polyclinic Hospital and College for Graduates in Medicine.

THAT the rectum and its diseases are considered as worthy of but little attention is evidenced by the *very little* attention they receive from the teachers of our colleges and universities. On the contrary, that they are deserving of profound study by the student and practitioner of medicine is attested by the complaints of the sufferer, the expensive exploiting of innumerable ointments, the suggestive circular of the charlatan, and the inability of the Regular to cope with them.

In order to intelligently and successfully treat any diseased condition, we must be able to recognize it. I quite lately read an article on the treatment of piles, wherein the writer boldly makes the assertion that, in a large experience of more than 20 years in the treatment of hemorrhoids, he has never seen a solitary case requiring operative treatment. Truly, such teaching is demoralizing.

Hemorrhoids are primarily a diseased condition of the vessels, as the books tell us, but they are also something more. The veins of the rectum are disposed to become dilated and varicose, because they are devoid of valves; their position being perpendicular, the column of blood is being pumped up-hill, and the resistance is great because of the weight of the column above, while the peculiar office of the rectum subjects them to conditions not elsewhere commonly found to exist.

Much more frequently, perhaps, than is generally admitted, this dilation and varicose condition is designated hemorrhoids. This definition is radically wrong, as it totally ignores an advanced pathologic condition absolutely necessary to constitute piles. Undoubtedly, this previous dilation, etc., is a preliminary step in the formation of a pile, but it does not by any means constitute the disease; for given this varicose state, with

opportunity for the vein to empty itself, you will never produce a pile. Should, however, an obstruction of any kind exist, sufficient to keep the vein distended, congestion is produced; and, because of the friction to which the parts are subjected, inflammation is added, an inflammatory exudate is deposited, and a tumor is produced—a tumor that can be both seen and felt, which by plastic infiltration under favorable circumstances tends to grow larger. When the veins within the external sphincter-muscle are affected, the hemorrhoids are said to be internal. When those outside the muscles are involved, piles are called external. There is also a "combination" pile, partaking of the nature of both the internal and external varieties. Commonly two distinct kinds of external piles are described—a blood-tumor and a peculiar inflammatory condition of the integument.

This blood-tumor is said to be a clot enclosed in a cyst formed by a dilated vein, and we are taught that if we cut into it we evacuate this clot. I must take exception to this teaching. Instead of the vein forming a cyst enclosing this mass of blood, I am satisfied that the vein-wall has ruptured and that the clot is not encysted at all, but lying loosely in the tissues, circumscribed but not encysted.

The pile due to an inflammatory condition of the integument is due to enlargement of flaps of skin existing naturally in certain individuals, and I have never witnessed this form of growth in persons having a smooth regular surface at the anal opening. Therefore, in my opinion, this growth is not to be included as a variety of hemorrhoid.

The most prominent symptom of external piles, often, in fact, the only symptom, is pain, whereas in internal piles it is often nil unless they are irritated or ulcerated. A patient suffering from internal piles may endure them for months or even years without special inconvenience, while one suffering from the external variety demands immediate relief. External piles are said to be much more frequently met than internal. My experience is opposed to this, as I am sure that I have encountered half a dozen internal to one external. I believe the opinion is due to the fact that the practitioner seldom makes an examination of the parts, but simply quiets his conscience by writing a prescription for piles after accepting the patient's diagnosis.

The causes of piles have been variously ascribed; but as a matter of fact, it is decidedly hard to trace them. Sedentary habits and constipation are "old standbys," but as supports they are gradually crumbling to pieces, as the disease is found as frequently in the robust individual, whose entire life has been spent in active pursuits in the open air, as in the puny, cadaverous fellow who spends hours perched upon a stool in a dingy foul-aired office. Pregnancy is a common cause, but it is quite evident that it acts mechanically by obstructing the lumen of the vessels; an overloaded condition of the rectum could be causative for the same reason; but that the simple atony of the muscular coat of the bowel is sufficient does not satisfy me. Displacement of the uterus is cited as a common cause, but many patients present themselves in whom none of the accepted causes are to be found, and in whom cannot be found any sufficient or probable cause.

While quiescent external piles (if in this state they can be truly called piles) are practically without symptoms, especially those composed of enlarged flaps of integument, it is the inflammatory condition, or the blood-clot exciting as a foreign body to inflammatory

reaction, that directs the sufferer's attention to his condition. Pain then becomes decided, a feeling of heat and fulness, and tenderness to pressure exists, while reflex symptoms form a prominent feature of the case.

External hemorrhoids are frequently but a symptom, if I may be permitted such a term, of other diseases, as ulcerations, fissure, internal piles, abdominal tumors, displaced uterus, enlarged prostate, etc. It follows that, in treating them, other troubles should be looked for and attended to at the same time.

We are taught that external piles are usually an unimportant matter, not often demanding operative interference. While not wishing to deny the possibility of resolution taking place under local palliative methods, I am constrained to say that return to the original condition, while agreeable to the patient, is not cure, and that such cases are like a smouldering fire, liable to light up upon the slightest provocation and demand constant attention for months and years.

One reason advanced in opposition to operation is that wounds involving the mucocutaneous surface do not heal kindly, are apt to degenerate into ulcers, etc., and that such ulcers are extremely hard to heal. Personally, I cannot subscribe to this teaching, and must affirm such has not been my experience. We are informed also that all that is needed oftentimes is to incise the pile, turn out the clot, and our patient is immediately at ease. It reads very prettily, but in practice it doesn't seem to meet the indications; in fact, it will be found that the knife excites additional inflammatory action, and our patient is made worse. By far the most satisfactory method of dealing with this form of pile is bold and free excision under antiseptic precautions.

With regard to the palliative treatment of external piles we can only say that we can hope to accomplish but little. We exhaust our ingenuity in efforts to relieve our patient; finally lose him because of failure. The books are profuse in instructions in this direction, and the journals occasionally contain infallible formulas, but it is only occasionally that you derive benefit from them. We are dealing with inflamed skin, or inflamed skin plus a foreign body—clot of blood—beneath it. Such conditions are not favorable to absorption of local remedies.

If your patient is suffering, induce him to go to bed, and apply a series of generous poultices as hot as he can stand them; then after the subsidence of the acute trouble an astringent and sedative lotion will probably give you more satisfactory results than almost anything else. Always impress upon the patient the fact that you are simply affording him temporary relief and insist upon the advisability of radical cure. If he expresses his willingness to submit, let me impress upon you not to fall into the fatal error of waiting until the acute trouble "quiets down," but operate immediately, as then you remove both the trouble and its cause.

Internal piles are a much more serious trouble than the external, yet to the individual patient it does not appear so, as the one suffering from the external variety will complain most, because of pain and distress, while acute pain is prominently absent in uncomplicated internal piles. A patient suffering from internal piles will endure for weeks, months, and years the inconvenience of protrusion, staining of the linen, etc., without complaint. It is only when a complication supervenes, as ulceration, pronounced bleeding or perhaps inability to return his piles within the rectum, that he recognizes the necessity of medical advice. There appears to

prevail among doctors an idea that piles are usually situated high up the bowel. This is not so, the plexus involved is just above the line of junction of skin and mucous membrane. The degree of protrusion varies greatly in different cases because of the greater or less size of the pile, but the point of origin is invariably the same, *i. e.*, the terminal venous plexus.

It appears to me not only useless but misleading to apply a variety of names to hemorrhoids, as the venous, the arterial, the capillary, the white, etc. It is far more convenient to make a division into internal and external; further, that internal piles when large will protrude, that the most dangerous form is the small internal—so-called capillary—because of the fragility and delicacy of its covering. They are just forming, are readily broken down and serious hemorrhages may result; while the large variety are most troublesome, as they are likely to protrude, become irritated by friction, inflamed and ulcerated.

It appears strange, but nevertheless it is a fact, that many physicians advise their patients against operation for fear of "being thrown into consumption," saying the bleeding acts as a safety-valve, etc. Such teaching is absurd, and in the light of the advances of physiology and pathology, is unworthy of an educated profession.

Other diseases are frequently associated with piles, often indeed acting in a causative relation to them; for example, displaced uteri, abdominal growths, affections of the bladder, prostate and urethra. So commonly are such troubles said to bear a causative relation to hemorrhoids that many surgeons claim it is useless to treat the piles until these troubles are corrected. I cannot endorse such teaching; on the contrary, feel perfectly justified, in fact, in duty bound to relieve my patient of suffering in this particular first, and cure the other troubles afterwards if I can. If I have, for example, a patient suffering from piles that constantly protrude, plus a large and displaced uterus, her uterine disease causing comparatively little trouble, while her piles inflict upon her constant distress, I do not feel justified in waiting for the gynecologist to repair the womb trouble, even granting, for the sake of argument, that the womb disease is the sole cause of the hemorrhoidal disease. I operate at once, knowing that I can afford her almost instant relief and put her in better condition for the gynecologist. Bear in mind I am addressing myself to hemorrhoids, not to a simple varicose condition of the veins. Moreover, I do not believe that correcting these troubles will cure the piles, though such treatment will undoubtedly relieve them and will cure simple dilation.

Internal piles that do not bleed and do not protrude present but few if any decided symptoms. The earliest symptom of importance is hemorrhage, and as the small, badly-organized pile is most apt to bleed and seldom protrudes, we must make an examination with the speculum to locate the source of bleeding. The next important symptom is protrusion, the degree of protrusion depending upon the size of the pile. The protruding mass causing little pain and being easily replaced within the bowel, assures us we are dealing with an uncomplicated case. If, however, decided pains exist we will find complications existing in the form of abrasions, fissures, ulceration, etc., a feeling of fulness, as of something still remaining within the rectum, the patient feeling he has not fully completed the act of defecation due to the tumors acting as foreign bodies. Reflex symptoms are very distressing at times, and the patient will complain of pain in the back, thighs, etc., while the entire

nervous system may respond to the irritation, and the patient be miserable generally. In persons of an advanced age there is a tendency for the tumors to remain protruded, owing to a relaxed condition of the sphincter. An examination should be made of all cases complaining of rectal trouble. Your personal interest demands that you make your own diagnosis and forbids you accepting the patient's.

The treatment of internal hemorrhoids can best be considered under the single head of radical cure. Palliative treatment is not worth wasting time on except as a means of inducing the patient to submit to operation. The hemorrhoidal tumor can be removed in a few moments, the cure is radical and complete; yet by education in a false theory and a temporizing method by the general practitioner, many of these sufferers fall into the clutches of the charlatan and are treated for months and years without benefit. There are only two operative measures for the radical cure of internal hemorrhoids worthy of consideration—the ligature and the clamp and cautery.

While the method by clamp and cautery has of late gained much headway and is advocated by many able men, I am satisfied that it can only be adopted in selected cases. For general use it has little to recommend it and much to discourage its use. We cannot feel sure that it has sufficient cautery effect upon *all* vessels, therefore hemorrhage is more liable to occur than after the ligature properly adjusted, recovery from the operation is slower, there is often considerable sloughing and we are all familiar with the extensive scar tissues following burns.

The ligature in the radical cure of internal hemorrhoids has withstood the test of time, and is accorded the endorsement of the most skilful surgeons of all countries. It is easy of execution, gives the very best results with less pain and speedier convalescence than any other method. Allingham, Sr., undoubtedly expresses the conviction of the profession in saying there is not within the range of surgery any proceeding worthy of the name of operation, exhibiting greater success and smaller death-rate than the ligation of internal hemorrhoids. In fact, when we consider that in thousands of instances the operation has been done under the most unfavorable circumstances by inexperienced and even ignorant operators, its success is phenomenal.

Notwithstanding the brilliantly successful record of this operation, there are certain details to be observed in the method of applying the ligature. The operation as usually performed does not appear to me to be the best, and is open to the serious objection of inviting possible infection, a risk to which I do not feel justified in subjecting my patient. See any textbook of surgery for description of classical operation. A better, less painful, eminently more satisfactory procedure and the one personally adopted, is to throw a strong ligature *around* the base of the smaller piles while grasped in the bite of the forceps, and put strongly on the stretch by an assistant, tying tightly and leaving as small a stump as is compatible with safety to the patient; this surface is cut off from the general circulation by the tightly drawn ligature, consequently there is not any danger of infection. For larger tumors a double ligature is passed through the base of the pile and tied tightly on either side and the redundant growth treated as above. Usually the patient is put to bed on light, easily digested diet, and in a week is discharged cured. In selected cases I have known patients to resume busi-

ness the day following operation without experiencing any inconvenience whatever.

The combination pile involves some cutting, but it is on the cutaneous surface only. Commencing at the junction of the skin and mucous membrane, the knife is carried cleanly and boldly around the tumor to the same point upon the opposite side, the pile is then grasped firmly at its base by the forceps and lifted well away by the assistant, a double ligature is then passed through the base and tied firmly both on the skin and mucous surfaces. Cut off the tumor as close as possible to avoid slipping, bring edges of skin round together by S. W. G. suture, and dress in usual way under strict antiseptic precautions. An important detail to bear in mind in forming the stump is to employ straight scissors for the reason that, if curved scissors are employed, the cut will be deeper in the middle than at either side, and might promote the slipping of the ligature, while the cut made by straight scissors or scalpel, owing to the compression exerted by the ligature, will bulge upward at center, and throw the edges downward, thus acting as an additional precaution against hemorrhages due to the ligature slipping from its position. Let me also insist upon a bold use of the scissors in forming the stump; do not cut off a *little* of the mass only. Bear in mind *why* you are cutting, keeping as close to the ligature as you dare, thus leaving as little tissue as possible to come away as the ligature cuts its way through, saving your patient much discomfort and inconvenience.

While this paper is specifically intended to set forth *what should be done*, it offers so strong a temptation to protest against a certain more or less popular method of *what should not be done*, that I cannot resist. I refer to the injection of carbolic acid and other irritants into the hemorrhoidal mass, in the expectation of radical cure. In spite of all that has been written of the evil results of such practice, I am grieved to say it still finds advocates among men whose medical education should be a guarantee of intelligence. This practice was devised some 20 years ago and was "*farmed*" out without regard to ability, to any one who could pay the price demanded, all being pledged to secrecy. After a time the secret was divulged and regular physicians all over the country adopted it. It gained for itself many strong adherents even among men of national reputation, until, appalled by the awful results, they one by one receded from their positions. However, I find it still in use in the hands of men who should know better, who are apparently undeterred by the evil results of others and are waiting for a personal experience. They will get it, too, and to their sorrow. In the meantime they quiet themselves with the argument that it is the man and not the method that is to blame. As a method of treatment it should not be countenanced by medical men; it is unscientific, fraught with danger, intense pain, and does not produce radical cure; at the very best it should be classed with palliative methods. We cannot predetermine just how much acid should be injected into the individual hemorrhoid; sloughing and great destruction of tissue are perfectly natural consequences, and fistulas, abscesses, and strictures are common results, while violent hemorrhage, pyemia, and death are not rare.

Largest Hospital in Europe.—Moscow has the largest hospital in Europe, with 7,000 beds. There are 96 physicians and 900 nurses, and about 15,000 patients are taken care of every year.

SOME CLINICAL EFFECTS OF AMMONIO-FORMALDEHYD.¹

By EDWARD L. KEYES, Jr., M.D.,
of New York.

THE more important effects of urotropin² (the ammonium salt of formaldehyd) have been widely exploited first in Germany and more recently in this country, so that the following data may be accepted as axioms:

1. The effects of urotropin are almost entirely confined to the urinary passages.
2. These effects are due, in part at least, to the liberation of formaldehyd in the urine, and
3. These effects are, heightened acidity, marked antiseptic properties, and variable irritation of the neck of the bladder.

It is my purpose to illustrate some advantages of the drug and certain limitations to its usefulness, as well as to suggest what has seemed a practical way of handling it to the best advantage.

The dose of urotropin is given as 15 to 45 grains a day, and most writers assert that the irritation, the pollakiuria and dysuria caused by it, is not to be found if the daily dose is kept below 30 grains. The following case, however, is an example of a sharp reaction to a much lower dose.

CASE I.—Mr. W. S., 70 years of age, has had locomotor ataxia and paralysis of the bladder since 1868. The use of the catheter long ago occasioned cystitis and pyelitis both of which are controlled by systematic catheterization, daily washing of the bladder with boracic acid or silver nitrate solution, and the use of salol, 45 grains a day. The catheter is passed five times in the 24 hours and causes no irritation whatever. Under this treatment the urine is acid and hazy, containing a trace of albumin. The centrifuge (3 minutes at 1200 revolutions) throws down a small deposit of pus and epithelium. The cloud is bacterial. December 29, 1898. Stop salol. Take urotropin 7.5 grains twice daily. January 11, 1899. No improvement; make urotropin 7.5 grains, three times daily. January 20, 1899. The new dose continued for four days, causes so much vesical irritation that the patient discontinues the drug for three days, in which time the irritation subsides. But two days more at the increased dose causes a more serious disturbance than ever. He has to catheterize himself five times during the night. The urine thus passed looks like the previous specimen, but the centrifuge now throws down 0.5% of deposit, leaving the supernatant fluid clear. This deposit consists of pus, squamous and transitional epithelium with few bacteria; there is a trace of albumin. This irritation subsided under liquor potassae and tinctura hyoscyami, the urotropin being discontinued. As a result the urine promptly became bacterial again, containing a small and variable amount of pus. No further attempt was made to administer urotropin until November, at which time 15 grains a day cleared the urine of bacteria and all shreds, leaving only a centrifugal deposit almost entirely epithelial, of $\frac{1}{4}$ of 1%, while 20 grains a day doubled the deposit and caused some irritation. Up to the present time any remission in the use of the urotropin is followed by a reappearance of the bacteriuria, while 15 grains a day keeps him clean.

In this case the action of the drug has been eminently satisfactory, for, although it has not yet effected a cure, and possibly never will, yet while respecting the marked idiosyncrasy of the patient, it has greatly aided him in his long fight against infection.

In marked contrast to the above case is the follow-

¹ Read at the Congress of American Physicians and Surgeons, Washington, D.C., May 1, 2, 3, 1900.

² Having used the drug impartially in the form of urotropin, cystogen, and ammonioform, with uniform effect, I refer to it simply as urotropin throughout this article.

ing, in which high doses were necessary to conquer a similar infection, although it was attacked while yet in an early and mild stage.

CASE II.—S. E., female, aged 28; three days before the delivery of her first child the patient had a chill followed by a temperature of 103°. The following day there was a second chill and the temperature again rose to 103°. No diagnosis was made and no further rise of temperature was noted until after delivery. Beginning with the first day there was afternoon rise of temperature up to 101° or 102°, with slight chilliness and general malaise. This was repeated daily for 4 or 5 days, when the urine, which had contained a faint trace of albumin and a few hyaline and finely granular casts, during the last 6 weeks of pregnancy, was carefully examined. It was hazy, and the centrifuge threw down a very slight deposit of leukocytes and bacteria, leaving the haze undiminished. A trace of albumin persisted. The diagnosis of pyelitis was made and the patient put upon urotropin, 20 grains a day, and large quantities of water. The temperature became normal within 48 hours and remained so, but the bacteriuria persisted. The urotropin was continued for a month with no effect whatever. After an interval of a month the urotropin was resumed at 45 grains a day for 9 days, at the end of which time the urine when passed looked the same as before, but cleared up in the centrifuge, showing a deposit chiefly epithelial (vaginal) and with but very few hyaline casts and bacteria. The albumin was undiminished. The urotropin was then continued at 15 grains a day for a month, at the end of which time bacteria were still absent and the albumin had disappeared for the first time in 6 months. At the present writing, two weeks since treatment was stopped, the urine obtained by catheter contains a granular haze which is quickly thrown down by the centrifuge, leaving the urine clear. The deposit is chiefly epithelial. It contains very few hyaline casts. There is no albumin.

The contrast of vesical irritability in these two cases is sufficiently startling to demand explanation. I believe that the matter is entirely one of idiosyncrasy. I have known 20 grains a day to irritate one woman's bladder and to soothe the vesical irritability of her daughter, and Case III is in marked contrast to Case I, in the great sensitiveness to instrumentation coincident with an ability to endure high doses of urotropin.

Neither can I explain why the effective dose for the long-standing inflammation of Case I was ineffective in the comparatively acute inflammation of Case II. The clinical point which this latter case suggests is that the drug must sometimes be pushed to the limit of endurance in order to conquer the inflammation, after which a lower dose will suffice to hold it in abeyance and finally to wear it out. A noteworthy point in both cases, and one which has come up in a number of others, is that the effect of urotropin on a urine swarming with bacteria may not be apparent at the first glance, but may require the aid of the centrifuge and microscope to show that the bacterial haze has been replaced by a purulent or epithelial cloudiness.

The following case, besides its contrast with Case I, already noted, exemplifies the effect of urotropin upon one of the commonest forms of urinary septicemia.

CASE III.—Mr C. D., 32 years old, comes with a "gleet" of one year's standing. He urinates once at night and every three hours by day. He has recently had two bloody emissions. He is sallow and anemic; his tongue is coated; he is constipated and says he has "remittent fever." He has quassimalarial paroxysms at irregular intervals. Local treatment at the hands of an excellent specialist has resulted in three urethral chills, inguinal buboes, and an acute epididymitis. Examination shows urethritis, prostatitis, vesiculitis, and cystitis. There is hydrocele on the right side. Ten days of forced milk and buttermilk diet, rectal irrigation, arsenic, salol and sandalwood oil, improved both the general and local conditions. Then two weeks local treatment with thallin, bichlorid and ichthyol (silver nitrate and protargol

having previously made him worse, and there being a strong suspicion of tubercle) netted him three days of urethral fever and dragged him down nearly to where he had begun. He was then put on three 7.5 gr. tablets of urotropin and 30 minims of eucalyptus oil a day, on which he improved rapidly, gaining four pounds in weight in three weeks. Eucalyptus was then discontinued, and the urotropin run up to four, five, and six tablets a day. This last dose proving irritant, he was kept at five a day for ten days, during which time, two months after he came to the office, he got married without permission and "lived happy ever after." Sexual intercourse harmed neither him nor his wife. Two months after his marriage, four months after the beginning of treatment, he was entirely well but for a few dotty shreds in his urine. The wife, seen at two and again at eight months after marriage, showed no signs of infection and is now pregnant.

I have obtained similar happy results in dilating strictures without a chill, in which I believe urotropin internally and silver nitrate locally were responsible for the result. In fact it is my custom to employ urotropin in any case in which urinary chill or septicemia are present, or threatening, especially in operative work.

The following case (of which the exact record has unfortunately been destroyed by fire) was, as much as anything else, the foundation for my present routine practice of administering urotropin before as well as after all operations upon the urinary organs. For the facts as well as the inferences I am indebted to my associate, Dr. C. H. Chetwood.

CASE IV.—Mr. A. B., about 40, submitted to an external urethrotomy for stricture. During the 24 hours following operation he passed but two or three ounces of urine. His temperature rose to 105°, his pulse was tumultuous and irregular, and he was apparently about to die of acute suppression of urine. Urotropin was then administered (7.5 grains q. i. d.) and within 24 hours the floodgates were unloosed, the temperature and pulse came down, and for two or three days all went well. Then to test its efficacy, the urotropin was withdrawn. Within a day the urinary excretion became much less and the temperature and pulse ran up again. Again the urotropin was administered, kidneys, temperature, and pulse promptly reacted and the convalescence thereafter was uneventful.

Since instituting the use of the drug I have several times observed a similar postoperative diuretic effect, though never in so marked a manner as in this first case; but in no case have I known the drug to have any diuretic or other beneficial effect on chronic uremia. How it might affect the acute uremia of Bright's disease, I have had no opportunity to judge. I have not yet met with a case of postoperative suppression since using urotropin.

One accident has occurred, however, in this connection, which I wonder at not having seen reported heretofore. It is certainly a serious mishap and one that is likely to occur frequently.

CASE V.—J. H., 65 years of age, submitted to suprapubic prostatectomy on February 22, 1900. For 2 days before operation the patient received 5 grains of urotropin 3 times a day. After operation the drug was continued at the same dose. Although the patient was in poor condition before operation, and the urine ammoniacal and foul (there were 32 stones in the bladder) there was neither suppression nor suppuration in the wound at any time. The upper part of the wound which, had been sutured, united by first intention, but the lower part, left open for drainage, was covered on the second day by a superficial leathery slough. This was attributed to the irritating urine. In spite of vigorous irrigation, however, the sloughing progressed, and by the tenth day, when the drainage tubes were finally removed, the whole wound was lined with a dense adherent membrane, while from the deeper parts long shreds of necrotic tissue were daily clipped away. The edges of the wound were be-

ginning to be raised and leathery. On March 8, the eighteenth day, the condition of the wound was worse than ever. The skin along the line of union and about the suture-holes in the upper part of the wound was thickened, white and surrounded by an area of congestion. In the groin, where there had been some chafing, and about various papules caused by adhesive plaster, a similar change had taken place. The wound itself had not healed in the slightest. Nowhere was there any suppuration.

The condition of the wound and the surrounding parts could be attributed to nothing but the irritating urine. The condition resembled nothing more than a case seen in consultation, in which a wound in the scrotum which had been irrigated for some time with formalin, assumed an appearance of malignancy for which it was proposed to perform castration, but which disappeared as soon as the formalin irrigations were stopped. Accordingly I suspected formalin irritation, and exchanged the urotropin for salol.

March 12. The wound is decidedly more healthy-looking. March 18. Great plaques of slough are shaling off from the sides of the wound which is manifestly closing; although the patient's bladder has been irrigated per urethram, since the tenth day, he urinates today 2 ounces—for the first time.

After this the healing of the wound was slow but uneventful. On April 4, the suprapubic fistula had closed, and 8 days later the wound was entirely healed.

My experience with other operative cases, both before and since, convinces me that this tendency to slough is an idiosyncrasy, comparable to the tendency to bladder-irritation; but though unusual it is none the less important.

To sum up the conclusions suggested by this modest array of cases, it may be advanced as a basis from which to discuss the virtues of the drug that:

1. Urotropin seems to be almost a specific in the treatment of some cases of acute catarrhal pyelitis, uncomplicated.
2. To prove effective it may have to be administered in high doses until the urine is practically clear of bacteria, after which a smaller dose may suffice.
3. In judging the effects of the drug, the centrifuge and microscope should be employed.
4. The dose must not be sufficient to cause pollakiuria and dysuria by irritation of the neck of the bladder.
5. The possibility of such an irritation cannot be overlooked, even when very small doses are employed.
6. Urotropin is extremely serviceable as a prophylactic of the various forms of urinary septicemia and urethral chill.
7. Its routine employment both before and after operations on the urinary passages is indicated.
8. The urine containing urotropin occasionally has an escharotic effect upon wounds, which may constitute a contraindication to its employment.

Cardiac Dilation.—Stinchfield (*St. Paul Medical Journal*, September, 1900) divides cardiac dilation into acute and chronic. The former occurs suddenly and, therefore, the heart-walls are thin. In the chronic form the dilation is accompanied by hypertrophy and always comes on more or less slowly. One or more cavities may dilate, and the cause is always in front of the dilation. A dilation of the left heart is sure to be followed by a dilation of the right; and obstruction to the pulmonary circulation also causes dilation of the right heart, hence that side is most frequently dilated. Besides its effect upon the heart itself, dilation causes sclerosis and brown induration of the lungs, nutmeg

liver, stony kidney, chronic gastritis and an enlarged, dark, hard spleen. Acute dilation is caused by violent muscular exercise. Symptoms, physical signs, auscultation, diagnosis, prognosis, etc., are discussed by the author. In treatment 2 indications are to be met: (1) to keep up the general nutrition as well as possible; (2) to support and control the action of the heart. When compensation fails or dilation becomes excessive absolute rest is of prime importance. [A.B.C.]

The Value of the Newer Signs and Procedures as Aids in Diagnosis.—Head (*The St. Paul Medical Journal*, September, 1900) calls attention to the value of **Koplik's spots** in making the diagnosis of measles. In 1896 Koplik called attention to these spots. He said that on the buccal mucous membrane and on the inside of the lips we invariably see a distinct eruption. It consists of small irregular spots of bright red color. In the center of each spot, by strong daylight, can be seen a minute bluish-white speck. This eruption is almost absolutely pathognomonic of measles, and appears in the invasion stage or early rash stage. According to statistics which the author has collected these spots appear in 88% of cases of measles, and hence he regards them as a valuable aid to diagnosis. **Lumbar puncture** as an aid to diagnosis in meningitis is a procedure introduced by Quincke in 1891. The puncture is made between the second and third or the third and fourth lumbar vertebra. Cerebrospinal fluid is drawn off. In 123 cases of meningitis fluid was present in 117 and absent in 6. From these statistics we may draw the following conclusions: In diseases other than meningitis, the fluid withdrawn by lumbar puncture is usually clear and colorless. In some cases of meningitis the fluid withdrawn is clear. A bacteriologic study may help in the diagnosis of these cases. If the fluid is cloudy, milky or purulent, we are probably always dealing with a meningitis. Since this class embraces 84% of all the cases of meningitis analyzed, the value of lumbar puncture as a diagnostic procedure in meningitis is established. Failure to secure fluid when lumbar puncture is done does not exclude meningitis. **Justus' test** in syphilis consists of a fall in hemoglobin of from 10 to 20% following the administration of mercury to syphilitic individuals, either by inunction or subcutaneous injection. The author's conclusions, based upon statistics collected, are that this test is of little value in the chancre and in the tertiary stages, but of considerable value in the secondary stage, about 50% of cases reacting. **Kernig's sign** in meningitis consists of the impossibility of extending the patient's leg upon the thigh when the latter is at right angles to the body. From statistics collected the author concludes that Kernig's sign is present in 84% of the cases of meningitis, is not present in healthy individuals, but is present in some brain-lesions other than meningitis, viz., subdural hemorrhage, edema of the brain, gonorrheal arthritis, and general carcinoma of the brain. **Litten's diaphragmatic sign** consists of the following: If a person lies with his feet pointed straight toward a window and the chest exposed, there can be observed along both axillae a sort of shadow which descends during inspiration from above the seventh to about the ninth rib, passing up again during expiration. It is best seen in spare, muscular persons. The observer must stand with his back to the light. It can be seen in all normal persons, except the very fat and those who cannot take a deep breath. Litten claimed that his phenomena was absent in (a) conditions where fluid or air was in the pleural cavity, (b) where the pleural cavity was obliterated by adhesions, (c) advanced emphysema, (d) pneumonias of the lower lobe, (e) intrathoracic tumors low in the chest. **Babinski's reflex** was announced in 1898 and consists of a certain peculiarity observed in the plantar reflex which occurs in pyramidal tract disease. He noted that in the normal adult if one drew his finger nail lightly across the sole of the foot there would be a flexion of all the toes upon the metatarsus. But in disease of the pyramidal tracts this normal flexion was replaced by an extension of the great toe with or without extension and separation of the other toes. He claimed, (a) that this sign never occurred in normal persons or those suffering from functional diseases, (b) that it is the earliest of the objective signs of pyramidal tract disease to appear. He excepted from this statement newborn infants and patients with transverse myelitis. The author considers Babinski's reflex very reliable. [A.B.C.]

Cremation at Galveston.—Some of the public journals seem to think that the great disaster at Galveston will make cremation more popular. The direful spectacle of the stricken city, with its many funeral pyres, is, of course, an object-lesson in cremation on a scale that is unprecedented. It will doubtless make the idea of cremation more familiar to the public mind, and therefore may, in a measure, tend to promote the cause of incineration. As we interpret human nature, however, the incident may work also in just the opposite direction. Cremation at Galveston will be associated in the minds of many persons with the thoughts of the horrible necessity which resorted to it. It was not a matter of choice, but of emergency. It was one of the elements of the great tragedy itself, and has become part of the enduring picture which has been so vividly impressed upon the public imagination. We think that for many persons who have heretofore had a prejudice against cremation, there will now be a downright horror for it. Nevertheless, the example at Galveston appeals to the reason, even though it may shock the sentiments. Perhaps reason will eventually prevail in this matter, although, unfortunately, on this subject of the disposal of the dead, prejudice and sentiment, founded on long-prevailing customs, rituals, and beliefs, are well nigh immovable in some minds. From the hygienic standpoint the cremation of infected and putrefying bodies is just as much to be commended as a regular practice in every city and town as it was at Galveston after that appalling calamity.

The value of teaching of first-aid-to-the-injured is illustrated almost every day, but in no case more aptly than in that of a brakeman on the Erie railroad who fell from his train. A leg was cut off by the car-wheels, but with admirable presence of mind the man constructed a tourniquet with his handkerchief and knife whereby he stopped the hemorrhage. Even in this condition he built a fire in order to warm himself, and awaited the next train, which he signalled; he was taken aboard and to a hospital. We trust that the time will come when school children in the upper grades may be taught so much of "applied physiology" as will enable them to act sensibly in the case of the thousand emergencies sure to take place in after-life with themselves or their fellows. It is strange that almost all lay people "lose their heads" in accidents and in-

juries, and do precisely what should not be done. This is especially true when hemorrhage is present. Many people either faint or are seized with panic at the mere sight of blood—a possible echo of primitive barbaric blood-rites and blood-frenzies. To supplant this loss of control by calm and intelligent action according to the circumstance and condition, is one of the duties we owe to the coming generations.

The First Cholecystotomy and the Man who Performed it.—Probably many Americans are not aware that in addition to the credit for the first ovariectomy by McDowell, of the backwoods of Kentucky, the first nephrectomy by Walcott, of Milwaukee, the first successful hysterectomy for fibroid uterus by Burnham, of Lowell, Massachusetts, and many other brilliant achievements, America may also claim the honor for the first cholecystotomy, which was performed by John Stough Bobbs, of Indianapolis, Indiana. Dr. Bobbs' paper, recording his operation, first appeared in the *Indiana State Medical Society Transactions*, in 1868, and has recently been reprinted in the *Indiana Medical Journal*, 1899, Vol. XVIII, p. 177. Briefly, the facts with regard to the case are as follows: A woman, 30 years of age, had been suffering for 4 years with a tumor in the right side of the abdomen, which had given her considerable pain.

The true nature of the enlargement was in doubt before operation, but the woman insisted upon operative measures. On June 15, 1867, assisted by a number of medical gentlemen, Dr. Bobbs performed the following operation: An exploratory incision was made, extending from the umbilicus to the pubes. Extensive adhesions of the omentum to the adjacent tissues were found. The incision was then extended above the umbilicus, and laterally over the most prominent part of the tumor. Tearing through the adhesions with his fingers, Dr. Bobbs reached a sac about 5 inches in length and 2 inches in diameter at its widest part, containing pellucid fluid. As no pedicle could be discovered, the lower point of the sac was incised, when a perfectly limpid fluid escaped, propelling with considerable force several solid bodies the size of ordinary rifle-bullets. The gallbladder was thus emptied, the incision in its walls stitched, and the gall-sac returned to the abdominal cavity. The external wound was properly closed. Recovery was rapid and uneventful.

The patient was still living near Indianapolis 32 years after the operation, and we have noticed no account of her death. In a letter to the *Indiana Medical Journal*, she wrote many interesting details with regard to the operation and her condition. As she remembers, between 40 and 50 stones were removed from her gallbladder, but she thinks one was left behind, which still causes her some trouble.

Dr. Bobbs was born in Green Village, Pennsylvania, December 28, 1809, and died at his home in Indianapolis, May 1, 1870. He began to read medicine with Dr. Martin Luther, of Harrisburg, when eighteen years old, and later studied at Jefferson Medical College, Philadelphia, where he graduated in 1836. Later moving to Indiana, he helped to organize the Medical College of Indiana at Indianapolis, became professor of surgery and later dean of the faculty. He served in the Union Army during the Civil War, and distinguished himself both for his courage and skill as a surgeon. He was president of the Indiana State Medical Society in 1868, and his paper, "Lithotomy of the Gallbladder," appeared in the same volume of the *Transactions* as his presidential address. Dr. Bobbs was a scholarly man, and one of the greatest general surgeons of his day. As a citizen, soldier, and philanthropist, as well as a surgeon, his name will long endure.

"Applied Physiology" is an ideal of education the value of which is being recognized more and more. It is strange how long the profession has neglected the duty of elementary teaching, with common sense and yet with scientific sense, of the simple truths of practical, personal hygiene. To this neglect is at last in part traceable the terrible vogue of quackery, and the wide prevalence of medical superstition. The family medicine book and the patent medicine almanac are sad evidences of barbarism active in the most advanced civilization. Because of the profound importance to the whole community and to future generations, of these facts, we feel justified in calling especial attention to an admirable attempt, for the most part highly successful, to bring to the intelligent lay-reader the principal truths of personal hygiene from the standpoint of sound science and educated common sense. The book to which we allude is "A Manual of Personal Hygiene," edited by Dr. Walter L. Pyle, and published by Messrs. Saunders & Co. Every practitioner must have many patients, and every school and college teacher many pupils, to whom such a work as this could be recommended, and whom it would greatly benefit. The volume is composed of chapters on "The Hygiene of the Digestive Apparatus," by Dr. Charles G. Stockton; "The Hygiene of the Skin and its Appendages," by Dr. George Howard Fox; "The Hygiene of the Vocal and Respiratory Apparatus," by Dr. E. Fletcher Ingals; "The Hygiene of the Ear," by Dr. B. Alexander Randall; "The Hygiene of the Eye," by Dr. Pyle;

"The Hygiene of the Brain and Nervous System," by Dr. J. W. Courtney; "Physical Exercise," by Dr. G. N. Stewart.

We hope that in a future edition there may be taken up some questions omitted altogether or too briefly treated,—such as those of habits, good and bad, especially concerning the use of tobacco, etc. There is in the volume no trace of the silly attempt of popular medicine books to replace the trained and living physician by a book, or by rules, or by self-treatment, but throughout there is the aim to enlighten the mind and prevent physical evils by the principles of applied physiology.

An *Ophthalmologic Light* is apparently beginning to break upon the English profession. While a number of American oculists are guilty of ignoring and belittling the very thing of which they should be proudest, and wearily continue to grind out the wheezy monotone of endless papers on operations and inflammatory diseases, the President of the Section on Ophthalmology of the British Medical Association devotes his presidential address to the all-important subject of refraction and ocular headache. We hope that his bravery may hereafter encourage our ophthalmologists to devote at least one paper in forty to subjects constituting nine-tenths of their daily practice, and that the operative mania may in the next one or two hundred years be relegated to its proper scientific place. Dr. Brailey should be heartily congratulated by discerning American oculists, although he is compelled to throw the inevitable sop to the conservative Cerberus by saying (what is not true) that "the great majority of headaches are, of course, independent of the eyes." We can also smile as cynically as the lecturer when he tails up with the charming astigmatic glance at "the citizens of the United States, who are eminently affected by ocular errors, so that a series of doctors and operators has arisen to take charge of that special subsection of practice." What a picture is incidentally drawn in the histories of some of his cases,—for instance in that of the poor woman with only a slight exophoria who during 20 years had been ordered 18 changes of glasses by her London ophthalmologist, who each time increased her "supporting" prisms bases in. Her disease was a slight hyperphoria! Although the increase of adduction by prism-gymnastics and many other things routine in American practice have not been able to cross the Atlantic, we are too glad of the dawning to criticise the clouds that temporarily, we hope, obscure the sun.

The Neuron Doctrine and Insanity.—In these columns recently we discussed this doctrine as expounded by Dr. Barker in reference especially to diseases of the nervous system. It has been very evident to our minds that the ascendancy of this doctrine at the present time presaged a new method in psychiatry

also, and that our textbooks on insanity would have to be recast or written anew on lines in accord with this conception of the nervous system. This need has already been recognized by Bevan Lewis, whose attainments as an histologist would naturally incline him to recognize this doctrine in the way he has done in the last edition of his book. It has remained, however, for Dr. Henry J. Berkley to seize the opportunity fully, and to enter the field with the first entirely new textbook that is practically based upon the teachings of the new histology. Dr. Berkley recognizes in every one of the insanities an affection essentially of the neuron, and builds his book on a foundation of the intimate histology of the nervous system. This scheme is thoroughly scientific, and will meet wide approval. The period has gone by for what may be called the merely metaphysico-clinical study of insanity. There is something more demanded now than the old essays on classification, and the old terminology of mental affections which has been largely inherited from metaphysical writers. With improved technic the demand will be more and more for the revelations in the neuron in all forms of insanity. This demand is already bearing fruit, for, while the secrets of the morbid anatomy of insanity are not likely all soon to be revealed, they are evidently being disclosed more and more every day in the minute changes in the nerve-cells. In other words, psychiatry is assuming its true place as one of the physiologic sciences. The interest and importance to be attached to the neuron doctrine are nowhere greater than in this wide field, for while this cannot be said to be a new field it is still in large parts a fallow one. Its fertility is nowhere shown more strikingly than in the acute psychoses, the infections and autoinfections, the degenerations, and the terminal dementias. From this standpoint of histology there is gained a conception of mental disease which, to be sure, is not entirely novel to the more original and advanced thinkers, but which is still much needed for some of the more conservative workers in this field.

Common Sense in the Interpretation of Statistics.

—In the school of the future that teaches sanitary science there will have to be a few special lectures on the interpretation of statistics. It is very essential that only those familiar with all the facts shall draw conclusions from some of them. We have a very good example of this necessity in the rapid-fire conclusions of some observers that the use of antitoxin increases the liability to postdiphtheric paralysis; it must be borne in mind that the use of the antitoxin causes the recovery of a large number of severe cases that would otherwise have died, and from this class the increase of paralytic cases is really recruited. In a serio-comic editorial paragraph recently a highly esteemed contemporary predicts that Colorado will soon become an Adamless Eden because the number of deaths of males

far exceeds the deaths of females in that State, while the female birth-rate is the higher. If one simply remembers that Colorado is a frontier State, and that its population contains a vast excess of young adult males, who always predominate upon the frontier, the undue proportion of male deaths will be readily explained. Centers of population that have acquired a stability not found in new towns are the only ones in which it is at all safe to draw conclusions even from all the facts as recorded at one time. Other statistics are of value in their variations; but the appreciation of the relative value to be attached to each group of figures or each variation therefrom can only exist with the careful student who has a knowledge of all the circumstances. We have heretofore commented upon the same lack of investigation in other lines in some of our recent literature; for example, some of the English and at least one of our best American medical journals jumped to the conclusion that diphtheria could not exist at an altitude exceeding 5,000 feet above sea-level because some observer had reported an absence of the disease at some points having that altitude in South Africa. These sapient writers ignored dozens of published communications in regard to the existence of diphtheria at high altitudes both in Switzerland and the United States, some of the most virulent epidemics during the last two decades having occurred in towns 10,000 feet above the level of the sea. All of which serves to emphasize the fact that there is no insularity quite so self-centered as that of the citizen of a big city who has never been outside of his own metropolis and whose mental vision fails to see beyond the literature of the present moment.

The Proposed North American Medical Association.—A project to organize a so-called North American Medical Association, to be composed of members of the profession in the United States and Canada, is in the air. A whisper has even gone the rounds to the effect that, either by absorption or amalgamation or expansion, whatever one cares to call it, the present American Medical Association might merge its interests in those of the new organization. The powerful body thus formed, it is said, would represent to better advantage the profession of the New World in all matters appertaining to medical reform. Perhaps the intensely warm weather of late has tended to bias the judgment of the advocates of this plan. We think the proposal is not commendable, at least just at present.

First, and above all, no need exists for a North American Medical Association; second, the individual interests, aside from those of a purely scientific character, of the Canadian and United States members would be distinctly at variance. The fact cannot be too strongly set forth that one of the best reasons for the existence and support of a great medical organization lies in its ability to influence legislation in behalf

of the medical profession as well as of the people at large. A disunited, warring profession accomplishes nothing; good organization and unanimity of action exert an influence which is not to be ignored. This expression of fact is platitudinous, but it is a true one, nevertheless.

The American Medical Association wields a powerful political influence. The trend of Canadian politics, whether in relation to medicine or not, differs somewhat from our own. As an instance of the clash of interests that would result, were the amalgamation to be carried into effect, it is necessary merely to draw attention to the question of National as well as local quarantine along the Great Lakes and the St. Lawrence. This feature alone, combining as it does such varied financial as well as hygienic interests, instead of serving to unite the profession of the two countries, would be a constant stumbling-block to cordial relations. The differences of opinion as to export and import duties on chemicals, on scientific apparatus, even on live-stock, also would contribute to prevent that cordial oneness of effort which should be so desired in a great medical organization. It should also be remembered that a large number of Canadian practitioners are members of the Canadian Branch of the British Medical Association, a fact that would probably put an effective barrier in the way of the proposed union.

On the other hand, no objection could be raised, and every indication would favor admitting Canadians to nonresident membership in the American Medical Association, such membership carrying with it the privilege of presenting and discussing scientific papers at the annual meetings, but not that of voting or joining in debate on subjects relating to the policy of the Association. Such a combination of interests, with the limitations specified, would result in a feeling of closer comradeship, a freer exchange of views on the scientific subjects of the day, and of amenities which would reflect to the advantage of all. Instead of trying to bring about a combination in a way different from this, those professing an interest in the future of the American Medical Association might to better advantage direct their energies toward the advancement of County and State Association interests, and fearlessly attack some of the many evils which have been allowed to creep into the administration of the organization. The first of these should be a determined stand against allowing membership in the Association of men who are not, or who have not been, members of their own County or even State Associations, in direct violation of the Association's constitution. And there are others.

The Bacillus of Typhoid Fever.—Since the discovery of the bacillus of Eberth, in 1880, the progress of research in typhoid fever may be divided into three periods. In the first period, this bacillus, critically studied by Gaffky, was considered as without doubt

the specific agent of the disease. But the discovery of the *Bacillus coli communis* by Escherich opened a new phase. First skepticism arose as to the distinction between these two organisms, and then, finally, the specificity of the bacillus of Eberth was denied. Rodet and Roux believed that this microorganism was only a variety of the *Bacillus coli communis*. The third period was marked by the use of Elsner's gelatin and the discovery of the agglutinating of Eberth's bacillus by specific blood-serum. Thus the specificity of this bacillus was recognized anew, although full accord in this belief is not yet established and the theory of the colon origin of typhoid fever still has its partisans. In order to solve this whole question, Dr. L. Remy, of Liege, Belgium, undertook extensive investigations, and these he has reported in a paper in the *Annals of the Pasteur Institute*, a translation of which, by Dr. H. D. Geddings, has just appeared in the *Health Reports* of the Marine-Hospital Service. Remy's paper is long and technical, but his aims and results can be briefly indicated. For those persons specially interested, however, in this line of work, the original paper or Dr. Geddings' translation is indispensable. The work comprises three parts. First, bacteriologic researches upon the dejecta of typhoid patients, with a new process for isolating the typhoid bacillus from the stools. Second, researches into the antagonism between the typhoid bacillus and the *Bacillus coli communis*. Third, researches upon the typhoid bacillus in waters, and a method for proving the existence of the Eberth bacillus in river and drinking waters. Remy's conclusions are briefly as follows: By aid of a differential gelatin the typhoid bacillus can be isolated in the presence of the colon-bacillus. This was proved in a series of cases. The typhoid bacilli, thus isolated, belong to one and the same type and are agglutinated by experimental serum. These results confirm the observations of Widal and others. The typhoid bacilli isolated from the stools in the second week, as well as those obtained from the spleen at necropsy, show remarkable vital energy, while those found in the stools at the end of the disease have only feeble vitality. In some cases the typhoid bacillus was found in the stools when the signs of typhoid fever, including the serum-reaction, were absent; hence the author claims that the typhoid bacillus, as we know it, is the only sign, which taken alone, can justify a positive diagnosis of typhoid fever. In other infectious diseases the typhoid bacillus is not found in the stools. Finally, the constant presence of this bacillus in the stools in typhoid fever, and its absence from the stools in other diseases, render it possible to assert that the *Bacillus typhosus* is in truth the causative agent in typhoid fever.

Pure Food Products.—Some time ago we had occasion to call at a "spice factory," and were struck by the fact that hundreds of tons of marble chippings

were being pulverized and used in the manufacture of all sorts of "ground spices." We also learned that the floor sweepings of such factories were regular articles of commerce, and listed at graded prices,—we suppose according to the varying quantities of disease-germs, dirt, and marble-dust in them. We do not know what other methods of adulteration may be practised, but the incident came to mind upon the receipt recently of a card announcing that a trustworthy firm of chemists, Messrs. E. R. Squibb & Sons, had placed with druggists, for sale, the more common spices, pepper, etc., which they speak of as "equal in purity to any of their preparations." The plan seems to us to have a professional and hygienic significance, and worthy of commendation.

For the Allied Troops.—The Korean Emperor has ordered shipped 1,000 bags of rice, 2,000 bags of flour, and 500 cases of cigarets to the allied troops at Pekin as an expression of his goodwill and wishes for the success.

When Shall We Operate for Cholelithiasis?—Albert Kocher (*Correspondenz-Blatt für Schweizer Aerzte*, 1900, vol. xxx, p. 193) has of late taken the position that all patients who desire to recover from gallstones should be advised to submit to an operation. It is impossible to dissolve gallstones by dieting or the use of drugs, and their crumbling up, as Naunyn reports, is so great a rarity that it cannot be counted upon. Whenever there is repeated biliary colic or evidence of numerous stones or of stones of a size that will not pass without harm, operative intervention is indicated. We should not wait until secondary changes have occurred; inflammations, perforations or malignant degeneration, for spontaneous recovery is extremely rare. As to the method of operation, he advises in uncomplicated cases immediate suture of the gallbladder as soon as it is emptied. He reports 6 operations of this kind at the Berne clinic, perfect recovery resulting in all. [M.B.T.]

Difficulties in Surgical Treatment of Gallstones.—George Henry Edington (*Glasgow Medical Journal*, September, 1900) reports two cases of operation for gallstones. In the first of these the gallbladder did not project sufficiently to enable the surgeon to suture it to the parietal peritoneum; in the second the difficulties were occasioned by the presence of dense inflammatory adhesions. In the first case the first incision made was a vertical one 4 inches long in the right linea semilunaris, but it was found necessary to supplement this by an oblique one running upward from above the middle line of the vertical one and parallel to the costal margin. No gallstones were discovered until the bladder had been opened; a number of calculi were felt lying in pouched recesses near the neck of the bladder, evidently excretions of the hollows between the folds which are normally present in the mucous membrane in this situation; these stones could not be extracted. A nodule was found on the under surface of the liver which was at first thought to be a tumor, but which was probably a biliary concretion. There having been some return of jaundice, on the twenty-fourth day after operation olive oil was injected through the opening left into the fundus of the gallbladder. This seemed to have solvent action upon the stones that could not be removed and was followed by cessation of pain; the stools thereafter were well colored and 4 days after the injection the flow of bile from the fistula ceased. In the second case it was exceedingly difficult to locate the bladder owing to the extent and density of adhesions probably associated with a rupture of the viscus during a severe attack of colic. The operator was unable to examine the ducts owing to the weak state of the patient on the table, and the use of olive oil to dissolve the calculi proved futile even when injected directly against the stones. The stones in the first case were of laminated cholesterol, in the second case of bilirubin-calcium. [G.C.C.H.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Schools Closed.—The public schools of Marshallton, Pa., have been closed on account of the prevalence of diphtheria in that place.

Legacies to Hospitals.—Charles Sweeney, of Philadelphia, recently bequeathed a portion of his estate to the Woman's Hospital, Philadelphia Home for Incurables, and St. Joseph's Hospital.

Medical Schools Opened.—The important place held by Philadelphia as a medical center has been emphasized this week by the reopening of 3 large medical schools each with an increased attendance.

Oleo Dealers Held for Court.—Last week 9 more oleo dealers were held for court by Magistrate Stratton, of Philadelphia. The Food Commission has not relied entirely upon its agents, but has obtained the aid of the Pinkerton Detective Bureau in the crusade.

Calendar of Meetings of Philadelphia Medical Societies for the week ended October 13, 1900:

Monday, October 8—College of Physicians. Section on Gynecology.

Wednesday, October 10.—County Medical Society.

Thursday, October 11—Pathological Society.

Faith Healer Charged with Manslaughter.—"Dr." Victor B. Hall, Christian Scientist, and with a recipe for living forever, is back in Philadelphia after 6 months' mysterious absence, during which he has stood trial for his liberty in London, Canada. He treated a patient for pneumonia there, she died and the "doctor" was lodged in jail. His trial resulted in his release.

Bequests to Charity.—The will of Emmeline Macurdy, who died recently at Mt. Holly, N. J., devises \$5,000 to the Episcopal Hospital, and \$1,000 to the St. James Industrial School and Mission, both of Philadelphia. One-half of the residuary estate of \$100,000 was devised to the trustees of the fund for the relief of widows and orphans of deceased clergymen and the aged and infirm clergymen of the Protestant Episcopal Church.

Parents Sue Hospital.—In a suit instituted recently, John F. Matthews and wife, of Philadelphia, seek to hold the Presbyterian Hospital and Dr. Charles B. Worden responsible for the death of their son. The boy was injured by falling from a carriage. It is said he was examined hurriedly at the hospital and allowed to go home. Subsequently, it is averred, the boy was again taken to the hospital and died a short time after his admission.

Municipal Hospital Needed.—The medical profession of Camden, N. J., has presented to the Board of Health a petition signed by 56 physicians, asking that a municipal hospital be established. The petitioners, who include the leading physicians of the city, state that there is great need for the hospital, and ask that no time be lost. The board, which is mostly composed of physicians, unanimously voted in accord with the petition, and then referred it to the Conference Committee to consult with city councils.

University of Pennsylvania.—The medical department of the University of Pennsylvania has just announced some radical changes in the curriculum for the present year. The course of anatomy in the first year will be followed by physiology in the second year. *Materia Medica* has been changed from the first to the second year, and will be followed in the third year by the course in therapeutics. Another change is that of bacteriology from the second to the first year, and pathology from the second to the third year.

Mutual Aid Association.—Upon petition of Dr. J. B. Roberts, President of the Mutual Aid Association of the Philadelphia County Medical Society, Judge Penrose, in the Orphans' Court, has granted an order to prevent the consummation of a sale of the premises owned by the estate of

Albert Fricke, deceased. It was stated that Mr. Fricke left one-half of his residuary estate to the association, and that his executor sold the premises at public sale for \$50, subject to a ground rent, whereas there is said to be a party now willing to give \$500 for the property, also subject to the ground rent.

Memorial to Dr. DaCosta Proposed.—The Faculty of Jefferson Medical College have recommended that a laboratory of clinical medicine be established in connection with the proposed new hospital, to be known as the J. M. DaCosta Memorial Laboratory of Clinical Medicine. The proposed laboratory, if erected, will be not only a valuable addition to the college, but also a fitting memorial to one of our most eminent physicians. Dr. DaCosta's affection for his alma mater has enriched the museum of Jefferson College by the addition of his most valuable collection of drawings, charts, specimens illustrative of various morbid conditions, and models in wax, prepared by the best French artists.

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about \$180, will be made on July 14, 1901, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published, and must be received by the secretary of the college on or before May 1, 1901. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned upon application within 3 months after the award. The Alvarenga Prize for 1900 has been awarded to Dr. David De Beck, of Cincinnati, Ohio, for his essay entitled: "*Malarial Diseases of the Eye.*"

Vital Statistics of Philadelphia for the week ended September 29, 1900:

Disease.	Cases.	Deaths.
Total mortality		347
Inflammation of appendix 3, bladder 2, brain 7, bronchi 2, kidneys 16, larynx 2, lungs 12, heart 1, peritoneum 6, stomach and bowels 17		68
Lungs—tuberculosis of 50, hemorrhage of 1, edema of 1		52
Marasmus 21, debility 4, inanition 12		37
Heart—disease of 14, dropsy of 1, fatty degeneration of 4, neuralgia of 2		21
Carcinoma of breast 1, bladder 1, colon 1, face 1, liver 3, larynx 1, stomach 1, uterus 3, tumor of neck 1		20
Apoplexy 14, paralysis 5		19
Fremia 7, Bright's disease 8		15
Convulsions		13
Cholera infantum		11
Diphtheria	77	10
Typhoid fever	70	7
Casualties		7
Cirrhosis of liver		7
Septicemia 5, pyemia 1		6
Old age		5
Croup 2, membranous croup 2		4
Surgical shock		3
Scarlet fever	29	1
Abscess of side 1, abortion 1, asthma 2, aneurysm of aorta 1, burns and scalds 2, cellulitis 1, chlorosis 1, cyanosis 2, hip disease 1, drowned 1, dropsy 2, abdominal dropsy 1, epilepsy 2, malaria 1, remittent fever 1, gangrene of leg 1, hemorrhage of uterus 1, homicide 1, jaundice 1, locomotor ataxia 1, measles 1, obstruction of the bowels 2, arterial sclerosis 1, softening of brain 1, stricture of the esophagus 1, of rectum 1, suffocation—gas 2, suicide—shooting 1, syphilis 1, teething 1, ulceration of stomach 1, whooping-cough 1		

Pittsburg Academy of Medicine.—At a regular meeting held September 24, Dr. J. I. JOHNSTON reported a case of *chronic parenchymatous nephritis with general anasarca* which failed to respond to ordinary

treatment, but is improving under the use of the continuous bath and a single dose of pilocarpin daily.

Dr. W. B. EWING reported a case of *cancrum oris* in a child of 4, following measles. The actual cautery was used with apparently little benefit. Ten cc. of antistreptococcic serum were then injected. Two days later the slough separated and granulation promptly followed. This is the third case of recovery following the use of this remedy. Dr. J. C. DUNN said that an important factor in the above case was that it came under observation early, and that the treatment was mostly of an extended trial. He also reported a case of *tertiary syphilis* with unusual manifestations in which both parotid glands sloughed away.

Dr. E. W. DAY reported a case of *acute otitis media* with severe purulent discharge, subnormal temperature, pulse 40 to 60, severe pain over parietal bone and optic neuritis. There was no mastoid tenderness, but on opening it was found filled with pus and granulations. The skull was trephined about one inch above the external meatus and brain explored with a negative result. Prompt recovery followed, but a paralysis of the external rectus persisted. Dr. DAY also reported a case of *old mastoiditis* with an operative sinus over mastoid which presented the classical symptoms of cerebellar abscess. The skull was trephined and the cerebellum explored in all directions with a blunt probe without result. Autopsy showed a cerebellar abscess, with firm walls, which had been missed by the probe.

Dr. ELTERICH reported a case of *impetigo contagiosa* in a child of 4 with complete destruction of one eye from infection with impetigo virus. The case was sadly neglected by the parents. Dr. EWING reported a similar case with destruction of both cornea from infection. Dr. DUNN said that eye infection in impetigo contagiosa is somewhat rare, but it is remarkable that such infection does not occur more frequently. Ordinarily it is a very mild disease and requires little treatment.

Dr. ELTERICH reported an instance of concurrent infectious disease, varicella and scarlet fever. The combined eruptions gave the surface of the body a very peculiar appearance.

Dr. R. J. B. MILLER reported a case of severe dysentery which developed scarlet fever.

NEW YORK.

Dr. Roswell Park has been appointed Medical Director General of the Pan-American Exhibition.

A new hospital laboratory, to be used in connection with the Willard Parker Hospital, will be built by the city of New York. The estimated cost is \$20,000.

The New York State Cancer Laboratory has secured the services of a physical chemist in the person of Mr. Clowes, of London, England, who will investigate from that side of the causation of cancer.

Hospital for Tuberculous Individuals.—The Erie county, N. Y., Board of Supervisors has authorized the erection of a hospital for the exclusive treatment of tuberculous patients; it is to be built near the Erie County Hospital at Buffalo.

Hospital for Convalescent Poor.—The Hartley homestead near Yonkers has been purchased by Adrian Iselin, of New Rochelle, N. Y., and a hospital for the convalescent poor of New York will be established there. It is reported that between \$50,000 and \$75,000 will be spent on the building.

Physicians Sued.—Suit has been brought against 2 physicians of New Brunswick, N. J., to recover \$10,000 damages by a man who claims that he was wrongly placed in an insane asylum on a certificate signed by them. He was released in 3 days, and asserts that his seizure and detention were the result of a conspiracy to which the accused physicians were party.

The Pan-American Exhibition has authorized an exhibit of sanitary methods and appliances adopted or in use throughout the Western Hemisphere by health boards. It will cover methods of procedure in all matters pertaining

to sanitation, and an exhibit of appliances and models of plants in use for disinfection, ventilation, heating, water-supply, and garbage and sewage disposal, etc.

Sneezed for Twelve Hours.—Ferdinand Dahn is in the Flushing Hospital, L. I., having burst a bloodvessel in one of his ears. Dahn had a fit of sneezing, which lasted 12 hours, and which ended in the bursting of the vessel. Every method known was adopted to stop the sneezing, but without avail. The man was in a condition of extreme weakness when the attack ended. The physicians at the hospital say he will recover.

The Eye, Ear and Throat Hospital, at Buffalo, N. Y., have installed the largest **magnetic apparatus** in the country for drawing steel or iron from the eye. Mounted on a stand of brass and iron it weighs about 400 pounds, the magnetizer is 35 inches long and pointed at both ends, and the coil consists of 21,000 turns of copper wire, which, if charged with 500 volts, will furnish force sufficient to support a ton weight. This instrument is an improved Haab magnet and cost in the neighborhood of \$300.

Malaria and Garbage.—An epidemic of malarial fever has broken out on Coney Island; over 300 cases have been reported. It is said in Coney Island that the epidemic is the result of the dumping of garbage from Brooklyn on the west meadows along Coney Island Creek. Last week 65 carloads of refuse were dumped on the meadows, and the residents of Coney Island are up in arms. Dr. Hill says the dumping of garbage on the meadows is an open violation of the laws relating to the disposition of city refuse. Mosquitos are in great abundance about the garbage.

Women's Club vs. Mosquitos.—As the mosquito has no greater enemy than the fair sex, the fact that the women of certain towns are forming clubs to fight it is news of direful import for *Anopheles quadrimaculatus*. At Richmond Hill, near New York, they got a scientist to explain the value of kerosene oil as an exterminator of the young of the mosquitos. They explored the country around their town with boys provided with oil cans, and wherever there was a puddle, ditch, pond, or marsh, they poured oil generously on the surface. The result has been, we are told, that the residents of Richmond Hill enjoyed sitting out on their porches last summer, having almost complete immunity from mosquitos.

The American Electro-Therapeutic Association held its tenth annual conference in New York recently. A paper on **Galvanization** was read by Dr. A. Tripler, of Paris. Dr. Charles O. Files, of Portland, Me., and Dr. Wolff Freudenthal, of New York, delivered addresses on **Electric light as a therapeutic agent**. Dr. Files spoke of the value of electric light concentrated on the patient and said that in each of a great number of cases which he had treated according to that method there had been marked improvement. Dr. Freudenthal gave a description of his experiments with chemical rays. Dr. Massey, of Philadelphia, spoke of the method of treating tuberculosis of the glands of the neck by forcing electrolytic salts of mercury into those glands by electricity and gold electrodes. Two cases were reported as having been cured. Dr. S. Knap, of New York, read a paper on the **Etiology of tuberculosis; its course and termination**.

Hour of Death.—Dr. Pilgrim, Superintendent of the State Hospital for the Insane at Poughkeepsie, has made a careful study of the statistics of that institution for the last decade and finds that 20% of the deaths occur between 3 and 6 P. M., and the next highest rate was between 3 and 6 A. M., though the fewest deaths in any one hour were between 4 and 5 A. M. And it is not an uncommon thing to notice a clearing up of the clouded brain a few hours before the final change; especially is this true of those dying of phthisis, or after surgical operations, or from acute intercurrent diseases. Dr. Pilgrim also remarks that the number of cases diagnosed upon admission as acute melancholia are about 2½ times as great as that of acute mania. This not only proves that it is the rule for insanity to begin with depression, but it also shows that cases are sent to the hospital much earlier than formerly, before the later stage of mania has had time to develop.

Course for Trained Nurses at Columbia University.—At the request of the American Society of Superintendents of Training Schools for Nurses, the authorities of Columbia University are about to establish a special course in *hospital economics*, to be given at Teachers' College. The aim of the course is to fit persons who are already trained nurses for the responsible duties of superintendents of hospitals and principals of training schools for nurses. The prescribed course of study will include general psychology and its application in teaching; methods, practice, organization and supervision of hospitals and training schools, biology, physiology, hygiene, the production and manufacture of foods, home sanitation and management, bacteriology, and household chemistry. A series of special lecture courses has also been arranged.—[*Boston Medical and Surgical Journal*.]

Changes Needed in City Charities.—Dr. Robert W. Hill recently made an inspection of hospitals and almshouses in the city of New York. He advocates the removal of Bellevue Hospital and replacing it by a modern structure in keeping with the standing of the institution. He recommends the reservation of Blackwell's Island for the public charities of the city and making it, with Randall's Island, the permanent location of all charitable institutions. There are other islands farther removed from the city better fitted for prison use. Of the almshouse, the report says that the law against the sale or gift of intoxicants to inmates of public institutions should be enforced. The isolation of tuberculous individuals in the city hospital on Blackwell's Island is particularly urged. The Harlem Hospital, he declares, is "entirely inadequate to the service demanded of it and altogether unfitted for continued use as a public emergency hospital," although it has a competent medical staff and faithful attendants. The Fordham Hospital is similarly classed. The City Lodging House is called a worthy charity, and a better building is recommended for it. For the Emergency Hospital new quarters are recommended, if it is to be continued. The report calls the present condition of the institution "a disgrace to the city of New York."

The Buffalo Academy of Medicine—Section of Ophthalmology, etc.—At the regular meeting of this section, September 17, Dr. A. L. BENEDICT read a paper entitled **Eye-strain or gastric reflex**, in which he contended that too large an importance was attached to eye-strain as a causative factor in the production of abnormal conditions, it being rather the result of these conditions. He believes that gastric disturbances are usually at the bottom of those conditions laid at the door of eye-strain. In discussion, Dr. C. G. STOCKTON could not at all agree with the position taken, as his experience proved conclusively that eye-strain is repeatedly the cause of pathologic states and many times inducing disturbances of digestion which would produce the symptoms. Dr. A. A. JONES differed with the speaker, contending that while gastric reflex is an extremely important factor and may bear either the relation of the cause or the effect to eye-strain, eye-strain is very often the primary cause. Drs. E. STARR, A. G. BENNETT, and A. A. HUBBEL said that their experience in the correction of errors of the eye as treatment for diverse pathologic conditions leads them to the conclusion that eye-strain is often the sole cause of these conditions.

Section of Pathology.—At the regular meeting, September 18, Dr. H. G. MATZINGER presented a paper entitled **Blood-examinations**, in which he stated that out of all the mass of work of the past years the clinician had gathered little that was not subject to contradiction on the morrow or that he could verify and put to daily use; this was undoubtedly due to the difficulties of technic. That today it offers a ready-made absolute diagnosis only in some 5 or 6 diseases, while in the rest it ranks no higher in value than any other typical symptom; yet there are few diseased conditions on which it may not throw some light. He emphasized that a blood-count and hemoglobin estimation are of the greatest immediate and certain use in emergency work in surgery to determine whether the extreme condition of the patient is due to shock, concussion or compression, or due to hemorrhage, and in determining internal concealed hemorrhages such as may occur in extrauterine pregnancy. He pointed out that some subtle influence of which nothing is now known, is constantly at work keeping the number of both red

and white cells at a certain point, provided the physical conditions are the same and are normal, and that this is also true of the bulk of the blood notwithstanding that large quantities of fluid are absorbed periodically in the day into the blood-vessels. He called attention to the effects of vessel constriction more or less constant by pain, cold, emotion, vasomotor disturbance, suprarenal extract, etc., and to the changes in concentration and dilution by physical environment. He stated that while the profound physiologic changes are easily accounted for, the lesser ones are often overlooked and their value is difficult to gauge in the correction of observations. He called attention to the normal daily variation in the red cells and hemoglobin, and stated that these variations depended upon changes in the plasma and also to the subsidiary changes due to work, digestion and absorption. He spoke of the variation of the blood when taken from the different parts of the body surfaces and of the effects of massage, gravity, and exercise; the composition of the blood varying with the caliber of the arteries. In discussing the white cells he said that in a general way, other things being equal, their constant proportion has to do with the state of nutrition of the individual and therefore like the reds depends on the chemical condition of the plasma and its serum. He next discussed the mechanical difficulties, taking up in detail the Thoma-Zeiss instrument, the hemocytometer of Oliver (he recommended the Oliver on account of its simplicity and ease of manipulation), the Hoenach instrument, Gower's, Fleischl's, and the specific gravity method. He believes that at present uniformly reliable results cannot possibly be obtained; nevertheless, any careful, unbiased physician possessing a little knack and patience can get very useful information and help by studying the blood, and he recommends a specific gravity outfit for hemoglobin and an Oliver tintometer, a box of cover slips, and a microscope as all required to do good work. He closed by saying that it was to physiologic chemistry, and especially to a knowledge of the plasma to which we must look for the key to the situation—"the cipher code which will enable us to read clearly the meaning of what we are now able to observe." In discussion DR. A. E. WOERNERT thought that the writer was too pessimistic, that much aid does come and will come from even our present methods; he agreed with the large number and degree of sources of error in the technic. DR. JULIUS ULLMAN believes that at the present state of our knowledge a smear preparation will give sufficient data for practical clinical use, but of course was not applicable for record work; he called attention to the Widal test and its accuracy. DR. C. S. JEWETT thinks that we have benefited by even our imperfect knowledge and technic, and that the future study of the chemistry of the fluid portions of the blood and a simplification and perfection of instruments will make blood-examination more important than that of any other body fluid. DR. A. L. BENEDICT said that even today he classed blood examination with that of the urine and made them with even more frequency. DR. DELANCY ROCHESTER believes that the blood not only aids in diagnosis but is of great advantage in indicating treatment; in support he related several cases. DRS. GROSVENOR and HARTWIG related cases showing aid from blood-examinations.

DR. H. P. FROST presented a specimen of a heart ruptured through the wall of the left ventricle, being the third case occurring within a year at the Buffalo State Hospital. The patient lived 30 minutes after occurrence, suffering most intense dyspnea. Patient was a young woman and in apparent good health; specimen showed left coronary artery occluded by atheroma and the myocardium soft from fatty change. DR. ROCHESTER also reported a case similar in character presenting same pathologic anatomy.

NEW ENGLAND.

Boston Almshouse and Hospital.—Dr. Archibald J. Ranney has been appointed superintendent, to succeed Arthur T. Hopkins, resigned.

Boston Baths.—The total number of baths taken at the public bathing-places of Boston for the months of June, July and August was 1,950,608. In 1899 the total was about 1,500,000.

Yale University.—Dr. Otto G. Ramsay, of the University of Virginia, and resident gynecologist at Johns Hopkins

Hospital, has been appointed to a professorship in Yale University.

The Willard Hospital for the treatment of dipsomania and narcomania at Bedford, Mass., was opened recently. It contains 30 rooms and is beautifully situated. The grounds contain 175 acres.

Dog with Wooden Leg.—A veterinary surgeon of Milton, Mass., has made a wooden leg for a dog. It is a complete success and the animal stumps around sturdily awaiting the advent of a new cork leg which has been ordered for him.

The Harvard Medical School, the departments of which are now scattered over Boston, will soon be moved to Brookline, near Boston, where all the departments will be together, and will occupy 27 acres of land and buildings valued at \$1,000,000.

Milk Dealers Organized.—About 200 milkmen, both contractors and dealers, met in Boston recently to organize for their mutual protection and to prevent the cutting of prices. Remarks were made showing that the State Board of Health preferred the use of tin cans to glass bottles, and a committee was appointed to work against glass jars with the board of health. The association was organized under the title of the Milk Dealers' Association of Boston and Vicinity, and a constitution was adopted.

Inebriety among Women.—The *Medical Record* reports that at the recent annual convention of the Connecticut Catholic Total Abstinence Union, the president stated that while habitual intemperance among men was decreasing, alcoholism among women was becoming more common. This statement receives startling confirmation as regards England by the fact revealed by a parliamentary report on the working of the Inebriates Act, under which magistrates are able to commit habitual drunkards to reformatories, that of 92 such commitments 90 were of women. Of 6 inebriate reformatory institutions existing in Great Britain, no less than 5 are for women.

CHICAGO AND WESTERN STATES.

An epidemic of diphtheria prevails in Menasha, Wisconsin.

Smallpox is said to prevail in a logging camp near Ashland, Wisconsin.

An epidemic prevails at Rose Hill, Ill., and physicians disagree as to whether it is diphtheria or tonsillitis. Out of 60 cases, 30 have proved fatal.

Diphtheria in Sheboygan.—The parochial school of Sheboygan has been closed on account of diphtheria, there being over 20 cases in the immediate neighborhood.

Health Commissioner Appointed.—Dr. William R. Parkes has been appointed Commissioner of Health of Evanston, Ill., in place of Dr. A. B. Clayton, deceased.

Bequests to Charity.—Bequests have been given by the late Anna M. Biddle to St. Joseph's Hospital, the Home for the Friendless, and the Orphans' Home, of Logansport, Ind.

Music as a Cure for the Insane.—Recently music has been introduced "as a method" in the detention hospitals of Chicago. The result is being watched with great interest by nerve specialists.

Infection from Vaccination.—A case of infection following vaccination is reported from Logansport, Ind. The person suffered severely, soon developed tetanus, and death appears inevitable.

After Facts About Milk.—The Board of Health of St. Louis is collecting statistics to prove that tuberculosis is caused by bad milk, or from milk given by cows that are kept in confinement and not permitted to graze in pastures. It is the purpose of the board to supply these statistics from time to time and educate the public thereby to a demand for milk that is pronounced good by the sanitary authorities.

The International Association of Railway Surgeons will hold its annual meeting for 1901 in Milwaukee, Wisconsin, the second week of June. About 200 delegates will attend the convention.

Michigan Insane Asylum had an inmate who talked herself to death. She would talk for hours at a time. Recently a spell lasted far into the night and resulted in spasm of the glottis, from which she did not recover.

Canned Salmon Poisons Students.—The members of a Fraternity in a Chicago dental school were poisoned recently by eating canned salmon. Some of the men are still in a serious condition, but it is not thought any will die.

A Deaf-Mute Cured.—A St. Louis man, who had been deaf and dumb for 50 years, from an attack of smallpox, fell off a roof and recovered both hearing and speech. It might be unwise to introduce this method of treatment at the State Deaf and Dumb Asylum.

Cat Spreads Diphtheria.—Two girls of Minneapolis, Minn., are in the hospital with diphtheria and the family cat is charged with being the source of contagion. The bacillus of diphtheria of unusual vitality and size was found in cultures made from its throat.

Elephantiasis.—A colored woman recently died at the Cook County poor-house of this disease. Up to the time of death she weighed 500 pounds. It is said that her limbs were the size of an average man's body. Her coffin was 7 feet long, 4 feet wide, and 3 feet deep.

Bulldog with False Teeth.—Modern dentistry has been brought into use to relieve the sufferings of a bulldog in Chicago. An up-to-date dental bridge, with 6 teeth of gold and 2 of porcelain, was fitted to his mouth. The operation was performed in the office of Dr. O'Connor.

An Osteopath Held.—A. L. Thompson, of Milwaukee, has been held for violating the laws of Wisconsin, governing the practice of medicine and surgery. The complaint is that he represented himself as a physician and a specialist in surgery without having first obtained a license from the Wisconsin Board of Medical Examiners. It appears that he is not a graduate of a regularly incorporated medical college.

After Unlicensed Physicians.—Warrants charging the practice of medicine without a license have been issued against Drs. B. F. Folsom and F. L. Sweeney, of St. Louis, at the instance of Dr. L. C. McElwee, Secretary of the State Board of Health. Dr. McElwee says there are about 30 other physicians in St. Louis who are practising without license, and he will ask for warrants against them as soon as he secures sufficient evidence.

The Kankakee Insane Asylum, at Kankakee, Ill., former Superintendent William G. Sterns and several attendants of the institution are defendants in a \$25,000 damage suit begun by Daniel W. Storms. He bases his claims for damages on his detention at the asylum while sane and his abuse there, which injured his health. The president of the hospital trustees says the suit will never be tried; that it is political and the aim is to bring the institution into disrepute.

The Medical Society of the Missouri Valley held its annual meeting at Council Bluffs, September 20. The society voted to contribute \$25 to the Rush Monument Fund, and a resolution was adopted providing for a banquet after each meeting. The following officers were elected: President: V. L. Treynor, Council Bluffs; first vice-president, B. B. Davis, Omaha; second vice-president, F. E. Sampson, Creston; treasurer, T. B. Lacey, Council Bluffs; secretary, Chas. Wood Fassett, St. Joseph. Next meeting in March, 1901, at Omaha.

Charges of Unprofessional Conduct Against Minnesota Physicians.—The Minnesota State Board of Medical Examiners, according to the *New York Medical Journal*, has served notice on 4 Twin-City doctors—Edward N. Flint, William K. Flatt, W. C. Dieterich, and Alois F. Hinz—citing them to appear before that body on October 11, and show cause why their licenses to practise medicine should not be revoked for unprofessional conduct which largely consists of

advertising cures in the public press. The physicians propose to make a fight, and will give the law a severe test.

Wants \$6,000 for Smallpox Damage.—Peter Hagee, of Plainfield, Ind., has presented to the commissioners a claim for \$6,000. A quarantine was established over Hagee's house because of a case of smallpox. The first victim was a domestic employed in the house. Hagee's claim is for nursing the domestic, for household goods destroyed, for nursing his children, and for being deprived of their society, and because the disease left them scarred. He alleges that the quarantine kept the children confined to the house, so that they caught the disease, when otherwise they might have been removed to a place of safety. The claim was refused.

Cannot Enforce Pure Butter Law.—The State Board of Health of Missouri has decided to withdraw its butter inspector from St. Louis, and to make no further attempts to secure the enforcement of the pure butter law in that city as long as the bench of the Court of Criminal Correction is occupied by Judge Clark. The sale of oleomargarine as butter will then be practically unrestricted. The law prohibits the coloring of any substance desired to be used as a substitute for butter, and also the manufacture, sale, or keeping for sale, of any such substance. It does not place any restrictions on the manufacture or sale of oleomargarine, or butterine, if sold on its merits, and not as an imitation of butter.

Pledged to Raw Food.—A Raw Food Society has been organized at Chicago. It has been decided to try to bring about the organization of kindred societies throughout the United States. Resolutions were adopted which contained the following:

"Resolved, That it is our firm conviction that man could live much longer in proportion to the number of years required for development by eating raw food; ill health would be the exception, rather than the rule, and pestilence and contagious diseases would be wiped from the land. We believe that children reared on uncooked foods will become giants physically and intellectually."

Court Stops Diploma Mill.—An injunction has been issued against the Metropolitan Medical College of Chicago, restraining J. Armstrong, its president, and other officers from conducting its business in violation of the terms of the charter. The petition on which the injunction was issued was filed by Attorney John A. Barnes, of the State Board of Health. The law passed at the last session of the Legislature regulating medical colleges requires the judges of the courts to issue a temporary injunction on a petition without a hearing. Under this law upon the medical college is devolved the labor of furnishing proof that it is not conducting its business in the manner alleged in the complaint. The bill of complaint filed was a copy of the charter of the college issued in 1896, which authorized it to conduct a school where the various branches of medical science should be taught. The basis of the petition is the allegation that the college, while advertising that it is doing business in a legitimate manner, did not require the attendance in person of applicants for the doctor's degree. Copies of the advertising matter of the college were also filed, in which its officials state that it is fully equipped with appliances for enabling its students to master the science of medicine. The petition states that this statement is not true, as the college confers the degree of M.D. on applicants who answer a list of questions sent to them by the officers of the college.

SOUTHERN STATES.

The State quarantine property at Galveston, Texas, was damaged to the amount of \$50,000 by the storm.

Druggist Fined.—Albert N. Conner, of Washington, D. C., has been fined \$100 for not having clerks employed fully competent to discharge their duties during his absence.

A Noble Charity.—The corner-stone of the Confederate annex to State Hospital at Vicksburg, Miss., has been laid. The funds were raised by the Vicksburg Chapter of the Daughters of the Confederacy.

Dr. Thomas M. Lippitt, of Berryville, Va., who accompanied the marine guard to Pekin and was severely wounded there, is not recovering rapidly. The femur was severely fractured, suppuration followed, and union has not yet taken place.

Short Skirts in Schoolroom as a Sanitary Measure.—The School Board of El Paso, Texas, require the teachers to wear short skirts, since the long ones sweep along the walks and gather germs that may injure the health of the children.

Rappahannock Physicians Meet.—The Rappahannock Valley Medical Association met at Fredericksburg, Va., September 28. The feature of the session was the reading, by Dr. W. J. Crittenden, of Unionville, of a practical paper on "Cerebrospinal Meningitis," and a general discussion of the topic.

Kentucky School of Medicine.—A former member of the faculty asserts that the college is not 50 years old, and that it is not the lineal descendant of and legitimate successor to the medical department of Transylvania University. There may be trouble over the proposed celebration of the semi-centennial in the present year.

Woman's Medical College.—Dr. M. Ekstromer has been elected professor of chemistry and Dr. Henry Lee Smith, associate professor in diseases of children in the Woman's Medical College of Baltimore. The place of adjunct professor of hygiene, vacated through the absence of Dr. Edith Eareckson, will be filled by Dr. Louis Erich.

"Shields' Healing Balm" is the subject of a circular issued by Anderson W. Shields, of Washington, D. C., at one time pastor of a colored Baptist church. The circular contains a list of about 20 complaints which the medicine will positively cure, and directions for its use are given. He has recently been arraigned before the court on the charge of being an unlicensed physician.

Blood Poisoning.—It is reported that many of those engaged in recovering the dead after the recent flood at Galveston, Texas, are afflicted with blood-poisoning as a result of handling the decomposing bodies of the victims and from wading in the infected salt water in which the bodies lay. The city is now reported in a good sanitary condition and the general health of the people is good.

Emergency Hospital.—A competitive examination was held recently at the Emergency Hospital, Washington, D. C., to fill vacancies in the staff of physicians caused by the resignation of Dr. F. C. Walsh, senior assistant, and the early expiration of the term of Dr. Charles G. Smith, resident physician. As a result Dr. W. R. Moulden will become resident and Dr. Clifford Sperow, a graduate of the University of Virginia, senior assistant.

Guarding Against Typhoid.—Strict precautions have been adopted by Engineer Quick, of Baltimore, to prevent pollution of the water-supply of that city. Several inspectors are constantly watching all cases of typhoid located near the sources of supply. Particular attention is also paid to the final disposition of excreta. The water in the reservoirs is in very good condition and the muddy condition of the water at times is due to local causes in the pipes.

Washington Needs a Modern Morgue.—The attention of the Commissioners of the District of Columbia has been called to the necessity of a modern morgue. During an autopsy held at the morgue recently the stench arising from a partially decomposed body was so great as to drive the officers and employes of the police department from their quarters, which are adjoining, notwithstanding the fact that every precaution was taken to prevent such result.

Physicians Asked to Help.—Health Commissioner Bosley, of Baltimore, has sent to the physicians of the city a circular letter, asking their cooperation in fighting diphtheria and scarlet fever. He urges physicians to immunize all children that cannot be isolated from a diphtheria case, and says that the Health Department will provide the antitoxin where the family is unable to pay for it. The Department will also fumigate rooms and houses when necessary.

Dr. Jesse W. Lazear, formerly on Prof. William Osler's staff at the Johns Hopkins Hospital, and one of the demonstrators of clinical microscopy, died of yellow fever at Havana, September 25, aged 34. He had given up his position at the hospital to undertake special work in the army in Cuba, particularly in connection with the problems relating to malaria and yellow fever. He had charge of a laboratory in one of the military hospitals in the neighborhood of Havana. Dr. Lazear graduated from the Johns Hopkins University in 1889 and from the College of Physicians and Surgeons in New York in 1892. After 2 years' work in Bellevue Hospital he made a special study of bacteria in Berlin. In 1895 he became one of the house physicians at the Johns Hopkins Hospital and continued the study of germ diseases.

Orleans Parish Medical Society, meeting of September 22.—Dr. E. M. DUPAQUIER read a paper on **Alcohol as an etiological factor in diseases of the nervous system**; discussion on the essay was opened by Dr. P. E. ARCHINARD. The Louisiana State Medical Society will, at its next annual meeting, take this subject up in full; members of this section will be prepared to submit pertinent facts. Dr. E. W. JONES reported a case of blindness resulting from drinking vinegar. The patient was a lady, 30 years of age, who, being rather obese, was advised by her friends to drink vinegar to reduce her adipose tissue. She accordingly imbibed vinegar whenever she was thirsty, taking absolutely no water for the period of 3 weeks. At the end of this time she waked up one morning totally blind. Ophthalmoscopic examination revealed only a slight paleness of the optic nerve. Treatment has consisted of administration of strychnin, beginning with $\frac{1}{16}$ of a grain and rapidly increasing to $\frac{1}{4}$ grain daily. She can now recognize a letter an inch square at a distance of 10 feet, return of sight being gradual.

Richmond (Va.) News.—At a recent meeting of the Richmond Academy of Medicine and Surgery a committee was appointed to investigate and work with the Commonwealth's attorney in regard to the violation of the Medical Practice Law. There are several institutions here professing to "cure" different diseases, and the object of this inquiry is to ascertain if they have complied with the State laws regulating such practices.

Dr. E. C. Williams, who was recently elected to the chair of pathology and bacteriology in the Medical College of Virginia, has just returned from a year's study abroad.

An effort is now being made to separate the Street Cleaning Department from the Board of Health. Heretofore both of these branches have been under one head.

A fitting tribute to the memory of Dr. Hunter McGuire will be the naming for him of the splendid new annex to the Virginia Hospital. It will be called the "HUNTER MCGUIRE MEMORIAL ANNEX." When completed the annex will be used entirely for charity patients and will contain 75 beds. The cost will be approximately \$30,000. The arrangement of the beds in wards will make it well adapted for clinical teaching. In addition to the wards there will be built a new teaching amphitheater capable of seating 275 students. The building will be modeled after the most improved designs of hospital construction. A handsome memorial tablet will be placed in the building by the Faculty of the University College of Medicine.

The rate of mortality of Petersburg, Va., for the month of September was 23.04% per 1,000.

CANADA.

Quarantine at Murray Bay.—Many members of the American colony at Murray Bay, a watering-place of the Lower St. Lawrence, have been quarantined for scarlatina in their families. One family made purchases of Canadian rugs, homespun cloths, etc., manufactured by the local French Canadian housewives, and these are believed to have carried the infection.

Against Immigration of Diseased Persons.—The Canadian Government is now taking measures to protect itself from the immigration of diseased persons by arranging for the inspection of all immigrants bound for Canada at the foreign ports where they are to embark. This is responsive to the action of our Government in establishing a sanitary cordon abroad. We have secured from the steam-

ship companies which bring immigrants to Canada manifested to the United States a promise that they will let no diseased persons come, and a similar assurance from the railway companies entering this country from Canada. The course proposed by the Canadian Government completes the protective circle.

MISCELLANY.

Dawson Needs Ice.—The city of Dawson in Alaska is in need of an ice plant and a contract has been given for an ice machine to be placed in a cold-storage warehouse. The cost of ice last summer was at the rate of \$100 per ton.

To Pave and Drain Havana.—The municipality of Havana has been offered a complete sewerage and paving system for the city, in accordance with plans officially approved, for \$10,600,000. The offer is by Michael J. Dady, of Brooklyn, and is under consideration.

Fever Stamped Out at Santiago.—Owing to the efforts of the officers in charge of the Department of Santiago and Puerto Principe, no case of yellow fever has been reported there since December. The streets are swept daily, and previously infected houses have been 3 times disinfected. An inspection from house to house is made by surgeons and thousands of gallons of carbolic acid and tons of chlorid of lime have been used.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended September 29, 1900:

SMALLPOX—UNITED STATES.

			CASES.	DEATHS.
			Reported.	
ALASKA:	Port Safety	Aug. 25	2

Obituary.—LAWRENCE M. HICKMAN, of Haddonfield, N. J., September 23, aged 43.—S. M. PIERCE, of Cedar Falls, Ill., September 24.—E. N. WEBSTER, of St. Louis, September 25.—SAMUEL SMITH PURPLE, of New York, September 29, aged 78.—RICHARD H. WHITE, of New York, September 22, aged 32.

Smallpox at Cape Nome.—The Surgeon-General of the Marine-Hospital Service has received a report from Assistant Surgeon B. H. Earle, at Port Nome, Alaska, announcing that the epidemic of smallpox there has been stamped out, the last patient having been discharged from the detention hospital August 6. There was a total of 24 cases and 1 death during the epidemic. Occasional cases of smallpox are found among the neighboring Indian villages, and Dr. Earle reports having vaccinated a whole village.

New Food for the Army.—An experiment is to be made in Texas with emergency rations. From Fort Reno, 25 troopers will be sent on a 3 week's march. Rations in the form of concentrated chocolate and meat extracts will be taken. This form of rations is claimed to have all the merit of the ordinary bulky rations and may be used, if emergency requires, in the tablet form or in solution when convenient. The experiments will be watched with interest by army circles, and the effects both in the weight of the men and their general condition will be carefully noted.

Changes in the Medical Corps of the U. S. Army for the week ended September 29, 1900:

MACPHERSON, ALEXANDER T., hospital steward, now at Fort Michael, Alaska, will report to First Lieutenant R. S. Offley, Fifth Infantry, for duty with detachment ordered to Golvin Bay, Alaska.

HERMAN, DAVID L., private, hospital corps, now at Fort Michael, Alaska, will report to First Lieutenant R. S. Offley, Fifth Infantry, for duty with detachment ordered to Golvin Bay, Alaska.

SCHLAGETER, H. J., acting assistant surgeon, having reported in compliance with par. 2 S. O. 19, c. s., this office, will proceed to Nome, Alaska, and report to Major R. G. Ebert, chief surgeon of the department, for duty.

DIXON, JR., ARCH., acting assistant surgeon, is granted leave for one month from about October 10, 1900.

SCHERRER, ELMER A., acting assistant surgeon, will proceed from Fort Grant, Ari., to Fort Huachuca, Ari., in time to report to the commanding officer on or before October 10, 1900, for temporary duty during the absence on leave of Acting Assistant Surgeon Arch. Dixon, Jr.

GOMEZ, VINCENT, acting assistant surgeon, is granted leave for one month.

COOKE, ROBERT P., acting assistant surgeon, now on duty at Columbia Barracks, Cuba, will proceed at once to Havana and report to the commanding officer of the transport "Crook," for duty as attending surgeon on said transport from Havana to New York City. Upon completion of this duty he will return by the first available transport to Havana, Cuba, and thence to rejoin his proper station, Columbia Barracks, Cuba.

HAVARD, MAJOR VALERY, U. S. Army, chief surgeon of the division, will proceed to Rowell Barracks, Pasa Caballos, and Hamilton Barracks, Matanzas, Cuba, and make a medical inspection of these posts, and upon completion thereof will return to his proper station, Havana, Cuba.

STONE, RANDALL C., acting assistant surgeon, having reported at these headquarters, will proceed to the Presidio of San Francisco, Cal., where he will report to the commanding officer, Army general hospital, for temporary duty at that hospital, awaiting transportation to the Philippine Islands.

ROSS, CHARLES A., acting assistant surgeon, having reported at these headquarters, will proceed to the Presidio of San Francisco, Cal., where he will report to the commanding officer, Army general hospital, at that station, for temporary duty at that hospital, awaiting transportation on service abroad.

REYNOLDS, CHARLES R., acting assistant surgeon, having reported at these headquarters, will proceed to the Presidio of San Francisco, Cal., where he will report to the commanding officer for temporary duty at that post, awaiting transportation on service abroad.

EKWURZEL, GEORGE M., acting assistant surgeon, having reported at these headquarters, will proceed to the Presidio of San Francisco, Cal., where he will report to the commanding officer for temporary duty at that post, awaiting transportation on service abroad.

LYSTER, W. J., acting assistant surgeon, leave of absence is, by direction of the acting secretary of war, extended 15 days.

ALEXANDER, JAMES A., acting assistant surgeon, is relieved from temporary duty at the Presidio of San Francisco, Cal., and will proceed to his home, Monroe, La., and report by letter to the Surgeon-General of the Army for annulment of contract.

HEPBURN, JAMES H., acting assistant surgeon, is granted leave of absence for 1 month from about October 15.

FERGUSON, JAMES B., acting assistant surgeon, is granted leave of absence for 1 month and 14 days from about October 1.

CLOUD, First Lieutenant MARSHALL M., assistant surgeon, on account of sickness, is granted leave of absence for 3 months.

ASHAUN, First Lieutenant PERCY M., assistant surgeon, leave of absence is extended 14 days.

HENDRICKSON, WILLIAM M., acting assistant surgeon, is relieved from duty in the department of California, and will proceed from Fort McDowell, Cal., to Fort Flagler, Wash., and report for duty, relieving Acting Assistant Surgeon Stephen Wythe.

WYTHE, STEPHEN, acting assistant surgeon, will proceed to San Francisco, Cal., for duty in transport service.

PAGE, First Lieutenant HENRY, assistant surgeon, is relieved from further duty in the division of the Philippines and will proceed from San Francisco to Plattsburg Barracks, N. Y., and report for duty.

SPILLER, WILLIAM H., acting assistant surgeon, is relieved from duty on the U. S. transport "Grant," and will report in person to the commanding general, department of California, for assignment to duty on the U. S. transport "Hancock."

HYSELL, Major JAMES H., surgeon, U. S. Volunteers, in charge of the medical supply depot, Santiago, Cuba, is relieved from duty in the department of Eastern Cuba, and will repair to Washington, D. C., and report to the Surgeon-General of the Army for instructions.

CARTER, Major W. FITZHUGH, surgeon, is granted leave of absence for 21 days.

TANNER, WILLIAM T., acting assistant surgeon, now at Fort Myer, Va., will proceed to Fort Wadsworth, N. Y., and report for duty, relieving Acting Assistant Surgeon Edmund Barry.

BARRY, EDMUND, acting assistant surgeon, will proceed to San Francisco, Cal., and report to the commanding general, department of California, for transportation to Manila, P. I., and on his arrival there will report for duty.

CHAMBERLAIN, First Lieutenant WESTON P., assistant surgeon, is relieved from further duty in the division of the Philippines and will proceed to San Francisco, and report for further instructions.

CLAYTON, First Lieutenant JERE B., assistant surgeon, is relieved from duty at Vancouver Barracks, Wash., and will proceed to Fort Myer, Va., and report for duty.

KIRKPATRICK, First Lieutenant THOMAS S., assistant surgeon, is relieved from duty at Fort Myer, to take effect November 10, and will proceed to Fort Barrancas, Fla., and report for duty, relieving Captain Champe C. McCulloch, Jr., assistant surgeon.

MCCULLOCH, JR., Captain CHAMPE C., assistant surgeon, will proceed to San Francisco and report for transportation to Manila.

TRUBY, First Lieutenant A. E., assistant surgeon, is assigned to temporary duty at Columbia Barracks.

FIELD, P. CONOVER, acting assistant surgeon, is assigned to the headquarters, Second Artillery, Vedado.

MAZZURI, PAUL, acting assistant surgeon, is assigned to Cabana Barracks.

KEAN, Major J. B., surgeon, chief surgeon U. S. Volunteers, will proceed to Cienfuegos and Matanzas for the purpose of making an inspection of the medical department at the posts of Rowell Barracks and Hamilton Barracks respectively.

MAUS, Major LOUIS M., surgeon, will proceed to Trinidad and vicinity, Province of Benguet, for the purpose of making an investigation of that section as to suitability for the establishment of a sanitarium and convalescent camp.

GRIFFIN, WALTER E., acting assistant surgeon, will report to the commanding general, department of Mindanao and Jolo, for assignment to duty.

MEY, CHARLES F., acting assistant surgeon, upon relief by Acting Assistant Surgeon Gridin, will be relieved from duty in the department of Mindanao and Jolo and will report to the chief surgeon of the division for instruction.

MCPHERSON, WILLIAM E., acting assistant surgeon, is relieved from duty with the Twenty-first U. S. Infantry, and will report to the commanding general, department of Northern Luzon, for duty.

COX, First Lieutenant WALTER, assistant surgeon, upon arrival of Acting Assistant Surgeon William E. McPherson, will be relieved from duty in the department of Northern Luzon, and will report to the officer in charge, Army pathological laboratory, Manila, for duty.

LYON, PALMER H., acting assistant surgeon, is relieved from duty in the department of Northern Luzon, and will report to the commanding officer, Santa Mesa hospital, Manila, for duty, relieving Acting Assistant Surgeon Elvin W. Ames.

AMES, ELVIN W., acting assistant surgeon, upon relief, will report to the commanding general, department of Northern Luzon, for duty.

SROSO, First Lieutenant RICHARD P., assistant surgeon, is relieved from duty at the First Reserve Hospital, and will report to the chief surgeon of the division for duty in charge of the Army pathological laboratory, Manila.

CHAMBERLAIN, First Lieutenant WESTON P., assistant surgeon, is relieved from further duty in the division of the Philippines, and will proceed to San Francisco, Cal., and report by letter to the Surgeon-General of the Army for further instructions.

TANNER, WM. T., acting assistant surgeon, now at Fort Myer, Va., will proceed to Fort Wadsworth, N. Y., and report to the commanding officer of that post, relieving Acting Assistant Surgeon Edmund Barry.

BARRY, EDMUND, acting assistant surgeon, upon relief, will proceed to San Francisco, Cal., and report to the commanding general, department of California, for transportation to Manila, P. I., where he will report to the commanding general, division of the Philippines, for assignment to duty.

CLAYTON, First Lieutenant JERE B., assistant surgeon, is relieved from duty at Vancouver Barracks, Wash., and will proceed to Fort Myer, Va., and report to the commanding officer of that post for duty, and by letter to the commanding general, department of the East.

KIRKPATRICK, First Lieutenant THOMAS J., assistant surgeon, is relieved from duty at Fort Myer, Va., to take effect on or about November 10, and will proceed to Fort Barrancas, Fla., and report to the commanding officer of that post for duty, to relieve Captain Champe C. McCulloch, Jr., assistant surgeon, and by letter to the commanding general, department of the East.

MCCULLOCH, Captain CHAMPE C., assistant surgeon, upon relief, will proceed to San Francisco, Cal., and report to the commanding general, department of California, for transportation to Manila, P. I., where he will report in person to the commanding general, division of the Philippines, for assignment to duty.

Changes in the Medical Corps of the U. S. Navy for the week ended September 29, 1900:

ELMER, M. K., assistant surgeon, is detached from Boston Navy Yard, and ordered to accompany Battalion of Marines to Mare Island, then to duty on "Ranger."

THOMPSON, J. C., assistant surgeon, is detached from "Newark" on reporting of relief, and proceed home and wait orders.

GROVE, W. B., assistant surgeon, is ordered to duty on "Vermont."

ODELL, H. E., assistant surgeon, is detached from "Ranger" on reporting of relief, and ordered to Asiatic Station with Battalion of Marines for duty as relief of Assistant Surgeon J. C. Thompson.

STEPHENSON, B. F., surgeon, is detached from the "Baltimore," when out of commission, and ordered to examination for promotion at Washington Navy Yard, October 1, thence home and wait orders.

BELL, W. H., assistant surgeon, is relieved from additional duty at Norfolk Hospital and ordered to continue duty on the "Vixen."

DENN, H. A., assistant surgeon, order of September 22 modified, is ordered to report for duty on "Dorothea," October 1, instead of proceeding home.

ONNESBORO, K., assistant surgeon, is detached from the Naval Academy, and ordered to the "Vicksburg."

STUART, A., assistant surgeon, is detached from the "Fortune," and ordered to resume duties on the "Yankton."

ARMSTRONG, E. V., is ordered to report to commandant of New York Navy Yard for duty on "Vermont."

GRAVATT, C. I., medical director, is commissioned medical director from August 24.

WILSON, G. B., surgeon, is commissioned surgeon from February 7.

WAGGENER, R., pharmacist, is ordered to duty at Naval Proving Grounds, Indian Head, Md.

Changes in the U. S. Marine-Hospital Service for the week ended September 27, 1900:

MEAD, F. W., surgeon, is granted leave of absence for 1 day.

CARMICHAEL, D. A., surgeon, is granted leave of absence for 30 days, from October 15.

WERTENBAKER, C. P., passed assistant surgeon, is granted leave of absence for 3 days.

FOSTER, M. H., assistant surgeon, will proceed to Port Angeles, Wash., for special temporary duty.

MOORE, DUNLAP, assistant surgeon, is relieved from duty at Dutch Harbor, Alaska, and directed to proceed to San Francisco, Cal., or Seattle, Wash., and await orders.

FOX, CARROLL, assistant surgeon, is relieved from duty at Dutch Harbor, Alaska, and directed to proceed to San Francisco, Cal., or Seattle, Wash., and await orders.

PRIMROSE, R. S., acting assistant surgeon, is granted leave of absence for 7 days, from September 24.

WALKLEY, W. S., acting assistant surgeon, is granted leave of absence for 11 days, from September 24.

WETMORE, W. O., acting assistant surgeon, is relieved from duty at Cape Charles Quarantine and directed to proceed to Buffalo, N. Y., and report to medical officer in command for duty.

ALLEN, G. C., hospital steward, is granted leave of absence for 5 days.

MASON, R. MYRON, hospital steward, is relieved from duty at Dutch Harbor, Alaska, and directed to proceed to San Francisco, Cal., or Seattle, Wash., and await orders.

Yellow Fever.—Reports continue to arrive at Paris indicating the gravity of yellow fever in Senegambia. The troops returning to France tell pitiful stories of their experience. There is cause to fear that the disease may be brought to some of the French ports, but the authorities are taking every precaution.

Garbage Disposal in China.—Consul Fowler says: "The cleanest cities in China are Hang-Chow and Ning-Po. In the center of these 2 cities I have myself seen dogs eating bodies of babies; the rotting corpses of cholera cases; snakes winding in and out—in fact the most horrible filth on one side, while across the way was the glitter of gold, pomp, and luxury."

foreign News and Notes.

GREAT BRITAIN.

New Baths at Cheltenham.—The new baths erected in Cheltenham by the corporation were formally opened by the Mayoress on September 10. The cost of the building is nearly £10,000.

Plague a Notifiable Disease.—The Corporation of Dublin has, by special resolution, declared bubonic plague to be a notifiable disease for a period of 12 months, and a similar measure is under consideration by various other bodies, at Leeds and Hull.

Typhoid from Oysters.—An outbreak of typhoid has occurred at Ipswich which has, it is stated, been traced to the eating of contaminated oysters purchased of itinerant vendors, and a notice has been issued warning persons of the dangers attending this practice.

Open-Air Swimming Bath.—The London County Council is about to open for bathing purposes the largest of the lakes in Brockwell Park. The lake has been entirely lined with hydraulic mortar, so that it will be comparatively easy to secure its thorough cleanliness.

Bristol Medical Charities.—A "collecting dog" at Bristol, known as "Punch No. 2," has during the past 6 years collected over £100 for the local medical charities. His father, "Punch No. 1," was also a hospital collector, and between them the two dogs have collected 48,579 coins.

Open-Air Treatment of Phthisis.—It was reported at the last meeting of the managers of the Poplar and Stepney Sick Asylum district that their proposal to hold a conference of Poor-law administrators for providing accommodation for the open-air treatment of phthisis had been successful, and it was estimated that representatives of about 60 unions and parishes would attend the conference, to be held in the ensuing month at the St. Martin's Town-hall, London, W.C.

CONTINENTAL EUROPE.

Medical Attendance on Chemists.—A case has just been decided in France in which the executors of a deceased chemist refused payment of medical fees on the ground that custom, if not law, entitled a chemist to gratuitous attendance. The verdict was in favor of the claimant.

Instruction in Tropical Diseases.—In the University of Bordeaux, France, M. Le Dantec has been appointed to give a course of instruction on tropical diseases. In Holland the teaching of tropical medicine has recently been inaugurated by Dr. J. H. Kohlbrugge in the University of Utrecht.

Suicides in the French Army.—A dispatch to the New York Times states that suicides are frequent in the French army, and it is no secret that it is the result of the insupportable treatment which the soldiers are subjected to and the general brutalizing condition of life which they are compelled during 3 years to lead. In one week 3 suicides occurred in a single regiment. The colonel has issued an order of the day declaring that suicides will henceforth be treated as deserters, and that no military honors will be rendered them at their funeral. No man, it concludes, who is a real patriot will commit suicide; but nothing is said concerning the noncommissioned officers whose brutal treatment has caused these suicides.—[Medical Record.]

Sanatoria in Italy.—On August 23 the Administrative Committee of Charities of the Milan Savings Bank decided that a subvention of 30,000 lire annually should be granted to the sanatorium for the tuberculous poor of the city and province of Milan. The sanatorium, which is to be erected by private subscriptions is to be called after King Umberto I. The municipality of Leghorn has decided to found a sanatorium of the same kind with the same name. The Communal Council of Pisa has decided to allocate 30,000 lire for the foundation of a sanatorium which is also to bear the name of the late king. Thanks to the initiative of Drs. Pisani and Romeo a sanatorium for tuberculous patients has re-

cently been opened in the neighborhood of Catanzaro.—[British Medical Journal.]

The German Association of Public Health.—The twenty-fifth annual meeting of the German Association for Public Health was held in Treves, September 12 to 15. The hospitality of the town provided the accustomed convivial meetings and fete. PROFESSOR GAFFKY, who was a member of the German Plague Commission to Bombay, read a paper on **Precautions against plague.** He thought the due observance of the Convention of Venice would provide sufficient safeguard, especially in conjunction with the new Infectious Diseases Act. The inspection of ships should be done thoroughly by competent persons, and not be a mere formality. The disinfection of the excreta and sputum should be carefully performed, and those exposed to infection should be inoculated. PROFESSOR C. FRAENKEL and PROFESSOR INTZE read papers on **Water-supply for towns by damming valleys.** The former was inclined to think ground water preferable from a hygienic and a dietetic point of view, and since the water in the other case was really a surface water with all its impurities, it would always be necessary to filter it. Professor Intze, from the engineer's standpoint, drew attention to the greater regularity and permanency of such a supply over the ground water. PROFESSOR PRAUSNITZ read a paper on **Infant mortality from diarrhea, and its prevention.** He showed statistically how the mortality fell chiefly on the poor and destitute. He attributed it chiefly to insanitary dwellings and deficient air, and did not think artificial food had much to do with it, nor did he expect much improvement from sterilizing the milk. Although the etiology of the disease was referred to, nobody seemed aware of Ballard's observations on the ground-temperature, nor the fact that municipal sterilization of milk has been successfully tried in both France and England. On the third day there was a discussion on the housing of the working classes. The good work already done in Great Britain was frequently referred to. There was general agreement that where a municipality destroyed dwellings, it should provide fresh ones; but speakers were much divided on the question as to how far the city should otherwise provide dwellings, and apparently the majority were of the opinion that no part of the cost should fall on the rates, nor should the city in any way damp competition.

MISCELLANY.

Obituary.—WILLIAM COPELAND, of Staindrop, County Durham, September 16, aged 54.—RAYMOND COURTEEN, of Gloucester, September 17.—ROBERT S. COCHRANE, of Longford.—PROF. KORSAKOFF, of Moscow, aged 46.—JOHN A. LOTHIAN, of Glasgow, aged 62.—WILLIAM MAW HURTLEY, of Leeds, September 3, aged 44.

Poppy Cultivation in India.—The Secretary of State for India reports that the area of poppy cultivation in India had increased between the years 1890 and 1897, as stated by the Bengal Opium Department, from 770,000 bighas to 890,000 bighas. In 1898 the area was considerably below that of 1897. The Secretary of State further stated that the cultivators were perfectly free to sow food or other crops, and that he was unwilling to interfere with the rules and regulations of the system, which had worked well, and which gave full weight to the importance of controlling the traffic in opium and keeping it within bounds.

Vaccination in India.—During the prevalence of small-pox in India recently, measures have been taken to introduce vaccination among the natives, but this has met with opposition because of their strange superstition as to the occult powers of the color white. Dr. Anna Fullerton, formerly connected with the Women's Medical College of Philadelphia, and now occupying a professor's chair in an Indian medical school, writing of the attitude of the natives toward vaccination, says: "They have a belief that India is to be delivered some day (from British rule) by a native who has white blood flowing in his veins; and they think that the English (and they always class English with Americans) are trying to find the person with white blood in order to kill him and thus prevent India being rescued from English possession." They regard with suspicion every step taken to make vaccination compulsory during the present epidemic.

14. Tuberculous Lesions from a Clinical Point of View. EDMUND OWEN.

1.—Hart opened the discussion of **puerperal fever** in relation to **notification**. The objections to notification are: (1) The difficulty of defining what one means by puerperal fever; (2) the risk of the statistics being misleading from errors, unavoidable or otherwise, in diagnosis; and (3) the supposed unwillingness of practitioners to notify unless in cases likely to end fatally. He recognizes 3 forms of puerperal fever: (1) The acute rapid form due to a large amount of poison and usually associated either with severe laceration or ruptures of the genital tract, or with the retention of much placental debris as in greatly adherent placenta or membranes; (2) the ordinary lymphatic form; and (3) the rarer venous form. It is this form which taxes the practitioner's skill in diagnosis the most; for there is here an absence at first of local lesions and the passage of the mischief insidiously through a blood channel. The supposed unwillingness of a physician to give notification of cases of puerperal septicemia is because in certain instances the onus of actually causing the condition rests on his shoulders. Our improved knowledge of antiseptics, however, and the greater care exercised in the management of labor, should eliminate this. Notification should, in the author's opinion, be a privileged communication; but it may become the duty of the medical officer to advise the practitioner who has repeated cases of septicemia, to cease obstetric practice for a time, to make sure that he is not, by some error in practice, actually causing the trouble. The advantages of notification are obvious: (1) We get statistical information as to whether puerperal fever is increasing or diminishing, or some factor causing the condition may be discovered; (2) it would aid in prevention by putting the medical officer upon the track of careless medical attendants or nurses. Enforced notification virtu-

ally compels the municipality to provide hospital accommodations for suitable cases. [w.k.]

2.—Targett reports a case of **cephalotripsy** for the **after-coming** head, notable for the complete absence of labor-pains in the ordinary sense of the term, the uterus being in a state of primary inertia from first to last. Of the sites recommended for perforation, the suboccipital was chosen as less difficult to reach. When crushing is necessary, in using the cephalotribe, insert one blade in the suboccipital perforation, while the opposite blade is applied over the face; for thus the best grip is obtained. The advantage in crushing the head is the prevention of laceration in its delivery. [w.k.]

3.—**Human placentation** in the first stage has proved to be almost a perfect copy of the process which Hubrecht studied in *Erinaceus*. The primitive blood lacunae give origin to the intervillous spaces; out of the trophoblastic septa between the lacunae the first villi will develop, sprouts of mesoblastic tissue penetrating within them. After the intervillous spaces have become wider and the villi longer, the connection with the maternal tissue is loosened and absorbed, and the tips of the villi are free. Von Tussembroek, as the result of her studies upon the second stage in human placentation, gives the following conclusions: (1) The macroscopic form of the human placenta is accomplished about the sixth month of pregnancy; (2) at that period the decidua reflexa has almost totally disappeared; (3) the reduction of the decidua reflexa is the effect of mechanical pressure; and (4) the reduction of the villi of chorion is chiefly effected by the obliteration of the intervillous spaces between chorion and reflexa. [w.k.]

4.—Doran, in discussing **fibroids**, admits that their physiologic and pathologic relations to the ovaries are not yet certainly known and the prognosis of their growth is uncertain; but they usually tend to get smaller about the menopause. Most fibroids require no operative treatment whatever, but some should be removed by surgical procedure. A fibroid of the broad ligament always tends to grow large and press upon important organs and should in every case be removed. Retroperitoneal hysterectomy is the best of recent improvements in the radical treatment of uterine fibroids. Panhysterectomy, claimed by some as a greater improvement, entails more dangers at time of operation; besides, as in the more conservative procedure, ligatures cannot be dispensed with. In Doran's experience removal of both ovaries does not entail very formidable results. In over 100 double ovariectomies in his own practice he has traced only 2 cases of severe neurosis, and in one of these the patient was neurotic before operation. [w.k.]

5.—The fact which does most to discredit **vaginal hysterectomy for cancer** is its use in unsuitable cases. Scharlieb claims that this procedure should not be attempted on cases in which the disease has spread beyond the uterus locally; or has already infected the lumbar, iliac and other glands, or distant organs; or lastly, cases in which some other grave constitutional state exists, such as diabetes or Bright's disease. If such cases are not avoided the death-rate will rise. The lessons to be learned from 46 cases reported by her are: (1) It is well worth while to operate for cancer of the uterus while that organ is still freely movable, and there is no obvious extension beyond it; (2) it is not worth while to operate unless the whole disease can be removed; and (3) that the responsibility in this matter lies between the general practitioner and the specialist. The family doctor to whom the patient usually complains should not be content with ordering ergot, rest, and change of air, but should insist on examining every patient who has profuse or irregular uterine hemorrhage. [w.k.]

6.—Byers divides the causes of **postpartum hemorrhage** into 2 groups: 1. Uterine atony, the bleeding in these cases arising from the uncompressed vessels in the placental area. 2. Wounds of any part of the parturient canal, without necessary uterine inertia. By far the most numerous cases belong to the first group. In the majority of cases, postpartum hemorrhage sets in without warning, though some things may put the physician on his guard, as hemorrhage at previous confinement, rapidly succeeding pregnancies, the combination of want of exercise, and the consumption of too much food and stimulant, elderly primipara, etc. Chloroform does not promote postpartum hemorrhage if care is taken not to deliver too rapidly. The 2 measures

for the prevention of postpartum hemorrhage are the proper management of the third stage of labor, and the important principle, never to deliver in the absence of pains. Two factors in the third stage of labor are the separation of the placenta and its expulsion with the membranes. Nature should be allowed to separate the placenta, and then if she is not equal to the second task, the accoucheur may assist her in expelling the already separated placenta. In cases of secondary uterine inertia in which labor comes to a standstill, the proper line of action is, not to slip on the forceps and deliver, but to give a dose of opium; the woman will then fall asleep, after a time pains will come on again, and she will probably be delivered without any instrumental assistance. In instances of placenta previa after bimanual version, the delivery must not be hurried, but time must be allowed for the uterine pains to come on again. When from the history or the symptoms postpartum hemorrhage may be anticipated, precautionary measures are recommended, such as slow delivery of the fetus, its birth being followed down by the hand on the fundus; the puncture of the membranes when the os is nearly dilated; and after it is fully dilated, the giving of 2 teaspoonfuls of liquid extract of ergot. If hemorrhage does occur from an inert uterus the first measure to be adopted is external uterine massage; second, the use of hot water, 118° F., in large quantities. The intrauterine tube should be so placed that the whole inner surface of the cavity is bathed. Salt, a teaspoonful to a pint, is preferable to creolin in the water as an antiseptic measure. Other measures are bimanual compression, packing the uterus with gauze and drawing downwards the uterus with a tenaculum, thus compressing the uterine arteries. When the hemorrhage has ceased, the patient should be kept quiet, her head low, the lower part of the bed being raised to facilitate the weak circulation. Subcutaneous injections of ether and strychnin are most useful, but our main dependence is in saline transfusion. [W.K.]

7.—Boyd presents a tabular analysis of 30 cases of **conservative surgery of the tubes and ovaries**. The results were distinctly good in $\frac{2}{3}$ of the cases, with 2 subsequent pregnancies. But in $\frac{1}{3}$ there were recurrent inflammation and in a few cases secondary operations. In others the relief was slight or none and there were 2 deaths. From all published statistics it appears that better results are obtained from conservative operations on the ovary than from those on the tubes, and the 2 sets of cases should be reported separately as in the present report. [W.K.]

8.—Purslow reports a case of **complete inversion of the uterus** of 3 years' duration. The patient was brought to the hospital 3 years after her last confinement, suffering from anemia and pain in the right iliac region. Examination showed that inversion of the uterus was the cause of the trouble. The inverted fundus was split from front to back, the broad ligament ligated from the inside and the uterus removed in sections. The ovaries were not seen during the operation. The patient made a satisfactory recovery and is now in good health. [W.K.]

9.—Horbaczewski's theory that the increase in uric acid excretion which occurs a few hours after a meal is due to a digestive leukocytosis and the consequent increased liberation of nuclein within the organism is epoch-making. The details of the theory have possibly not stood the test of 10 years experimental criticism, but this work has formed the basis of all subsequent work on the subject, and if it does not express the whole truth, it contains the essential germ of truth, namely, that we are to seek the origin of uric acid, in mammals at any rate, in the destructive changes that occur in nuclein. Further researches have shown that a well-marked digestive leukocytosis may occur after a diet of egg-white or even after a nonnitrogenous meal which is not accompanied by a rise in the amount of uric acid secreted. The theory has, therefore, been modified by supposing that the acid arises from the breakdown of the nuclein of the food, independently of any intermediate leukocytosis. According to Halliburton, the **origin of uric acid** from the nuclein of the food may be one factor; at the same time the origin of uric acid from the nuclein of the leukocytes is another; the 2 probably act together, and in one case the one, in another case the other factor may be more predominant. There is a third factor, which never yet has seemed to receive any attention; this is that the katabolism of the nuclein of other animal cells, such as those of secreting glands, may con-

tribute to the formation of the acid. Investigators hitherto seem to have got into the way of supposing that the leukocytes are the only cells whose nuclei need be given attention. They are the cells which lend themselves best to investigation, but after all they constitute a mere fraction of the total cells of the body. Another fallacy which appears to underlie a good deal of the work on the uric acid question is the habit of regarding the amount of uric acid in the urine as synonymous with the amount produced in the body. Recent experimental work points the other way. The uric acid produced in metabolism doubtless in great measure leaves the body by the urine, but all of it certainly does not; some may be retained within the body for a time; an exaggeration of this is seen in gouty concretions; some may be further oxidized and converted into urea and simpler products; some may enter into combination with other organic substances, lose its identity, and the nitrogen ultimately leave the organism, not only as uric acid but in other forms also. Another factor which is often neglected is the amount of purine substances that leaves the body in the feces. The work of Burian and Schur shows that every healthy adult excretes a certain amount of purine substances which is independent of his diet; this is the result of tissue-metabolism and may be termed "endogenous urinary purine." But when a man takes his ordinary diet, which contains articles containing nuclein, or purine compounds, the amount of urinary purine is increased by a part of the purine derived from his diet, and this increase may be termed "exogenous urinary purine." The "nutrition purine" does not pass wholly into the urine; a certain fraction remains in the organism, the purine double ring being broken down. The amount of the remainder (exogenous urinary purine) differs for different forms of food, and is but little affected by the individuality of the subject of the experiment. In the discussion that followed Hopkins quoted, as evidence that uric acid arises from channels other than nuclear breakdown, some additional experiments with meat extracts. He had prepared extracts which had produced more uric acid than could be accounted for by the alloxuric bodies present in them. Smith Jerome regards the following propositions in relation to uric acid formation as proven: 1. That the quantity of uric acid excreted may by starvation be reduced to a fairly constant minimum; and hence that a part of the daily output is independent of food taken; (2) that the quantity of uric acid excreted may be increased by the use of certain foods, and, therefore, that a portion of the normal output is under control and directly dependent on the quantity and quality of ingested food; and (3) that food which increases the output of uric acid contains alloxuric nitrogen. He regards as not proved the following: (1) That we know the source of the uric acid produced in inanition; (2) that we can explain the want of fixed proportion between ingested alloxuric material and excreted nitrogen; (3) that the daily output represents production only, or the balance of production and destruction; (4) that uric acid is retained in the system; (5) that uric-acid formation necessarily depends on leukocytosis; (6) that we understand the precipitation of uric acid from urine, of which neither the acidity nor the percentage of uric acid is above the normal; (7) that the cause of deposition of sodium biurate in the tissues under pathologic conditions is at present known; and (8) that in pathologic states in which there are inflammatory conditions of certain tissues, together with deposition of uric acid in urine, and of sodium biurate in tissues, there is a causal relationship between the phenomena in question. Haig is of the opinion that by influencing solubility on the one hand, and introduction on the other, almost any relation of uric acid to urea in excretion may be met with, or produced; but this is no proof that formation is altered, and, taken over a long period, it would be found quite unaltered. [J.M.S.]

10.—Parsons sums the results of his experiments on **dilation of the pupil from stimulation of the cortex cerebri** as follows: Dilation of the pupil, like other effects of cortical excitation, is best obtained with slight anesthesia, and it is only obtained from those parts of the brain which are concerned in eye-movements. When well marked the dilation of the pupil is accompanied by all the usual effects of stimulating the cervical sympathetic. The effect is usually more marked on the opposite eye. The effect is diminished, but by no means abolished, by section of both sympathetic nerves

in the neck. The effect is abolished by section of the oculomotor nerves intracranially, subsequent to section of the cervical sympathetics, and under these conditions the pupils are immobile. The effect is not abolished on either side by section of the corpus callosum, but stimulation of its cut surface results in the usual bilateral pupillary reaction. Stimulation of the central end of a cut afferent or mixed nerve, for example the sciatic, still causes dilation of both pupils after section of both cervical sympathetics; i. e., through a reflex inhibition of the third nerves. Unequal constriction of the pupils from stimulation of the cortex has not yet been obtained. [G.B.W.]

11.—Carlier read a paper before the Section on Physiology before the British Medical Association, on the **changes in the cell of the newt's stomach before and after secretion**. As soon as the cell begins to part with the stored-up zymogen the nucleus commences to produce at the expense of its chromatin a new antecedent substance, viz., prozymogen. The production of this substance is facilitated by the movement toward and the spreading out of the chromatin immediately beneath the nuclear envelope. This prozymogen must pass into the cytoplasm in a liquid form, as there is no evidence of it within the nucleus, and when poured out into the protoplasm it remains in the neighborhood of the nucleus without being at once converted into zymogen, but remains as a compound of considerable stability, increasing in amount until the first complement has been produced. This stage is marked by the change in the reaction of the remaining chromatin, and no more prozymogen can be manufactured until a new supply of chromatin has been reproduced in the nucleus from some constituent of the cytoplasm. As soon as the zymogen granules have become exhausted, the cytoplasm begins to take up material from the lymph, probably of an albuminous nature, as its appearance in the cell is marked by a change in reaction. This ingestion from the lymph of proteid material permits the rapid conversion of prozymogen to zymogen, which is retained in the cell until such a time as the nuclear chromatin shall have been completely restored. The renewal of the chromatin is brought about by the entrance into the nuclear juice of an easily coagulable substance (probably a proteid material among other things) which is the meaning to the great increase in the number of the lanthanin granules at this time. Chemically, chromatin contains nucleic acid and an albuminous substance. It is very stable and acts as an acid to bodies less acid than itself. In order that this stable body shall pass into the cytoplasm, it is necessary that it should be rendered soluble; in this process some of the albumin is removed and goes to form the nucleolus. Being now useless in the nucleus the nucleolus is extruded into the protoplasm, there to be disposed of. The more acid part of the chromatin passes into the cytoplasm, where it remains in an invisible state unless the phosphorus and the iron that it contains are unmasked and revealed by dyes. The repair of the nucleus can only be brought about by the passage into it of substances from the cytoplasm which probably unite with the nucleic acid in the nuclear juice to form a material analogous to chromatin, that is, the blue staining lanthanin. One must look to the nuclear juice to find the earliest indication of the synthesis by which chromatin is built up from the simpler compounds. The nucleolus is in part, if not in entirety, composed of effete material which is tolerated in the nucleus for a time, but expelled either entire or after fragmentation as soon as its bulk renders it detrimental to the wellbeing of that body. [J.M.S.]

12.—Levy describes some of the more striking evidences of **fatigue of the cerebral motor cortex** which may be elicited by application of a faradic current of medium strength to a cortical motor center, the contractions of the correlated muscle being recorded on a moving surface. [J.M.S.]

1.—Owen devotes most of his paper to a criticism of the modern **treatment of tuberculous lesions** without suggesting very much that is new as a substitute. He believes that the surgeons have of late been too much under the influence of the experimental pathologists and bacteriologists. He fails to discover that iodoform is of any particular value in the treatment of tuberculous lesions and has discarded its use. He decries the present furor for the treatment of deformity from caries of the spine by forcible straightening and believes in a short time we shall hear very little about the method. In the treatment of vertebral caries absolute uninterrupted rest in a recumbent position he considers the only suitable method of dealing with these cases. He decries the use of all schemes, corsets, apparatus, and braces which he classes as American and finds them all wrong both in theory and practice. Prophylaxis of tuberculosis is most important and he suggests the desirability of preventing the marriage of tuberculous subjects. [M.B.T.]

2.—See abstract No. 6 from *British Medical Journal* in this issue.

3.—Shufflebotham prefers for the **chemical examination of the gastric contents** a test-meal composed of 8 ounces of bread cut in thick slices and covered with a little butter together with $\frac{1}{2}$ pint of weak tea containing sugar, but no milk. The stomach-contents should be withdrawn in 2 hours. After the gastric contents are filtered an alkaline reaction of the filtrate is only found when the patient has been taking alkaline drugs or when a pancreatic fistula opens into the stomach. The most common cause of acid reaction is hydrochloric acid in combination with proteids. The author prefers Gunzberg's test for determining the presence of free hydrochloric acid. [J.M.S.]

4.—Carvalho reports another successful case of **total gastrectomy** which he performed on a woman of 46, a native of Sao Paulo, Brazil. The patient was a weak, cachectic mulatto, who had suffered from stomach trouble for years and had become much worse during 6 months. After swallowing nourishment she was seized with acute gastric pains, followed after some hours by vomiting not infrequently mixed with dark blood. Her condition was becoming worse daily. On palpation a tumor the size of a turkey's egg was found in the epigastric region on the right side close to the costal margin. It was movable and painless and a diagnosis of probable malignant tumor of the pylorus was made. The patient had a weak, slow, regular pulse, and was not in particularly good general condition. Under chloroform-anesthesia a median incision was made between the ensiform cartilage and the umbilicus. A malignant tumor was found at the pylorus which was slightly adherent to neighboring organs, but affected most of the lymphatics of the stomach. The omentum was cut between ligatures, adhesions to the duodenum and the head of the pancreas were broken up. The duodenum was divided between two clamps and the stomach was isolated from below upwards, the lymphatic glands being extirpated at the same time. The stomach was clamped close to the diaphragm and removed. After careful disinfection of the cut surfaces the two extremities of the intestinal canal were united with a double row of fine silk sutures. The peritoneal cavity was cleaned and the abdomen closed with a triple row of sutures. The operation

lasted an hour and twenty minutes and the patient was in a state of profound shock at the end of it. She was freely stimulated and infused with 1½ liters of artificial serum. After injection of the serum the patient improved rapidly. She was nourished by nutrient enemata and small doses of alcohol were administered. Her recovery was comparatively uneventful and on the eighth day the sutures were removed, primary union having resulted. At the last report the patient was in very good condition. [M.B.T.]

6.—Lennander suggests that after every abdominal operation and every herniotomy the patient's bed should be raised at the lower end in order to assist the venous blood flowing from the lower extremities toward the heart. This measure tends to **prevent thrombosis**. The author had a number of cases of thrombosis following such operations, but since adopting this procedure he has had no trouble of this kind. [M.B.T.]

7.—Buchanan admits that Europeans newly arrived in India are more liable to be attacked by **heatstroke** than the natives of the country; this liability decreases for a few years following the first, and then more or less steadily increases in proportion to the length of residence in India. Dr. Sambon states that **siriasis** is not always to be found in the warmest regions. Buchanan shows that for downright fierceness of the summer heat, night and day, no part of India is less tolerable than the North-West frontier, the Punjab, and Sindh, and here it is that there is the greatest mortality from heatstroke. Again, Sambon claims that **siriasis** only prevails in the lowest regions and coast districts; on the other hand, Buchanan holds the lowest regions are the Burmah coast, the Bay Islands, and the West Coast, and it is exactly here that the very lowest ratios for heatstroke are obtained. The statement about the restricted altitudinal range of heatstroke, which the other writers have arbitrarily fixed at 600 feet, is not borne out, since the worst two stations are Peshawur and Nowshera, with the heights above sea level of 1165 and 1100 feet, respectively. In fact, the influence of height has little effect *per se* till we reach levels where elevation is combined with coolness of the atmosphere, as in the hill stations, the majority of which are well over 5,000 feet above sea-level. It can also be shown that the disease is by far the most prevalent in the months when the heat is greatest. While looking upon heat as the most important factor in heatstroke, we must also bear in mind the great influence of the usually predisposing cause, as age, length of residence in the tropics, occupation, exposure, unsuitable clothing (as the tight-buttoned and belted uniform of soldiers), intemperance (perhaps especially beer-drinking), overfatigue and overcrowding, want of ventilation, and previous illnesses. [J.M.S.]

8.—Two women, aged 58 years and 31 years respectively, inmates of a workhouse, were at work in a large laundry provided with a stove and a good-sized hot-air chamber for drying clothes. At 6.45 in the evening, another woman, on entering the room, found them both lying on the floor near one end of the room about 4 feet from a closed door leading into an airy wash-house. In both cases the bowels had acted involuntarily. The women were lying close to each other at the foot of a form in front of a long table. The elder woman had her feet on the form on which it appeared she had been sitting and she was covered with vomit. A nurse who was summoned found her completely stiff all over. Her arms were drawn up and her eyes were fixed and looked strange; but after she was removed she became very sick and apparently revived. At 7.45 E'gcod found the patient dead, although there was good color in her lips and face. The younger woman was also in bed; she was groaning and crying and at the same time opening her eyes widely and staring wildly around. The pupils were fully dilated and insensible to light, though they reacted in a quarter of an hour after. The breathing was noisy and rapid, and panting in character; 10 or 12 respirations following each other quickly in succession and then ceasing for a few seconds, but there was no regular cycle. No pulse could be felt at the wrist and no cardiac impulse was perceptible. There was present a rapid semiflexion and pronations of both forearms by which means the hands were brought together as if for the purpose of rubbing them. It was quite a coordinated movement and one apparently accompanying the return to consciousness. In a quarter of an hour the patient became much more conscious. She was very excited and seemed frightened and complained of pain in the head. In another

quarter of an hour a faint pulse was perceptible at the wrist. As far as she remembered, she said, the first thing she noticed to be wrong was a "swimmy" feeling in the head, and she sat down on the form with her companion. The women had closed the windows of the wash-house in order that the fire which had been augmented for the purpose of cooking some potatoes on the lid of the stove might not be discovered. The body of the elder woman, at autopsy, showed no gross lesions. On looking into the stove when it was empty it was seen that the exit pipe was placed rather nearer the bottom than the top, so that there was plenty of room to pile up fuel above its level, thus blocking up the flue and sending the fumes into the room instead of up the pipe. The author is of the opinion that **carbonic acid** or **carbonic acid** or both were accountable for the **poisoning**. [J.M.S.]

9.—Finucane finds the most noticeable features in large English military hospitals among the South African invalids sent him for gunshot injuries, are the almost total want of surgical intervention required or any marked deformity and the trivial nature of the wounds produced by the Mauser rifle bullet. The history of most of these patients is that of rapid healing by first intention, with little or no suppuration. This is the result, he believes, of antiseptic occlusion by the first and final field-dressings. Nearly all of the wounds are subcutaneous flesh-wounds, escaping bones and joints in a marvelous way, though traversing tissues and cavities in close proximity. The lodgment of bullets in soft or bony parts or in cavities necessitating removal is an extremely rare occurrence. This is due, Finucane believes, to the velocity and shape of the projectile. The clinical fact of most interest is the large number of cases of functional impairment of nerve-sense and motor-power associated with psychical symptoms akin to nervous shock or those observed after railway accidents. These nerve-symptoms do not bear any ratio to the extent or size of the wounds inflicted, but have been noted as being more common in injuries of the lower extremities and the head in cases that look originally to be not severe. The implication of nerves or their sheaths is not a marked feature, and in most instances there is no local evidence of the bullet or its course having been near the track of the nerve. The prognosis in such cases is extremely unsatisfactory and no definite one can properly be given in less than a year. Modern **gunshot wounds** have apparently lost much of the seriousness formerly attributed to such injuries, and it appears that the resulting **nerve-shock** and injury to the nervous system are the most frequent sequels, and at the same time the most difficult to prevent and treat. The absence of local nerve-lesion or injury producing nerve-change is significant, and a number of cases observed would not support the theory of these symptoms occurring in nervous persons only. Nine cases are reported out of a total of 60 seen during 2½ months with symptoms of this character affecting the nervous system. [M.B.T.]

10.—Vintas reports the case of a man, aged 68 years. He had been for 7 years a soldier in the French army and had served all his time in Africa. Since then he had had no regular employment. The patient complained of cough, shortness of breath, hemoptysis, and pains across the chest, both in front and behind, between the shoulder-blades. His illness began 3 months previously after allowing his clothes, which had been soaked through with the rain, to dry on him. A week before admission he spat about 3 ounces of dark coagulated blood. The chest was tympanitic in front. The right base behind was somewhat dull. On auscultation rhonchi and sonorous and sibilant rales were present over the whole chest, both in front and behind. At the right base, behind, there was a very indistinct respiratory murmur and the vocal fremitus here was slightly impaired. Four days after the patient's admission he suffered from intense dyspnea and seemed to be on the verge of suffocation. His face was livid and covered with cold perspiration. His eyes were bloodshot and looked as if they would come out of their sockets. The muscles of forced inspiration were acting powerfully and both hypochondriac regions receded during inspiration. His breathing was about 60 per minute. His voice could scarcely be heard and the patient complained of pain and of a sense of pressure in the epigastrium and between the shoulder-blades. He had an incessant and harassing cough, and this would at times be relieved by the expectoration of a thick sanguinolent fluid. Suddenly his face became quite black and he gasped for breath;

his body was shaken with a severe fit of coughing; and tracheotomy appeared to be inevitable. But with considerable effort he succeeded in expectorating a dark mass of the size of a cherry stone, and this was followed by about two ounces of dark, semiclotting blood. He felt instantly relieved and sank back exhausted. On floating the little black mass in water it turned out to be a perfect cast of a middle-sized bronchus with its ramifications. It was yellowish in color and $3\frac{1}{2}$ inches in length. For the next 2 or 3 days he spat some mucopurulent fluid and felt much easier. Four days later he had another attack of dyspnea, not so severe as the previous one, but he complained of the same severe pain in the epigastrium and between the shoulder-blades. On this occasion he expectorated about 15 casts. They were this time very soft and friable and much whiter than the first one. On September 2 the patient had a third attack and died suddenly. At autopsy a soft, rapidly-growing epithelioma of the esophagus was detected. A cast was found projecting from the right bronchus into the trachea and blocking the already strictured lumen of the latter. It measured 2 inches in length and was milk-white in color. There was no trace of tuberculosis. The casts were composed of concentric layers of a lamellar fibrillated structure and leukocytes, pus-corpuscles, and some cylindrical epithelium, but very few blood-corpuscles were enclosed between the layers. They were made up of fibrin and not of mucus or of a cragulation necrosis of the bronchial epithelium, as was once thought. The condition was one of plastic bronchitis. [J.M.S.]

11.—A case of hydatid disease of the liver is reported which was discovered by the presence of daughter cysts in the stools. The patient was a strong, healthy man of 38, who possibly contracted his malady when engaged in caring for greyhounds 12 or more years previously. The patient suffered from pain resembling biliary colic, and followed by jaundice. It is suggested that the cyst probably discharged through the biliary passages, and that at times portions became impacted, producing colic, and that by spasm and irritation, or by rupture and discharge of the irritating contents of the cyst into these ducts, the jaundice was caused. No surgical treatment was undertaken, as the patient's condition steadily improved. [M.B.T.]

12.—Gamgee reports 2 operations for an excision of cranial meningocele. A girl, 6 weeks old, had a tumor the size of a large Tangerine orange on the back of the head. This tumor had a narrow pedicle which was situated in the mid line of the occiput, half way between it and the posterior fontanel. The tumor became tense when the child cried, and was increasing in size. A longitudinal incision was made over the tumor, the skin easily peeled off, and on incision the sac was found to contain clear fluid only. The pedicle was ligated and the skin wound closed. Four months after the operation the child's condition is perfectly satisfactory. A boy, 11 weeks old, had a tumor of the same general characteristics. Its greatest circumference was $10\frac{1}{2}$ inches. A similar operation was performed, and the child was discharged perfectly well at the end of 2 weeks. [M.B.T.]

1.—Holmes says that chronic inflammation of the nose should be divided into 2 stages: rhinitis chronica simplex and rhinitis chronica hypertrophica. These 2 stages, though resembling each other quite closely, can be readily

distinguished by the application of cocain, as in the simpler variety the turbinate contracts easily from the use of this drug, because there is as yet little increase in the connective tissue, but in the second the application has little effect in relieving the stenosis. In children and in the milder forms of hypertrophic rhinitis in adults treatment with astringent acids and the cautery will generally accomplish all that is desired, but when the second stage has developed there is only one successful way and that is by surgical interference. In order to destroy as little of the mucous membrane as possible, thereby avoiding the after-evils of crustation and dryness, Holmes suggests the formation of a bone scar. This he accomplishes by sawing off the lower edge of the enlarged turbinate with a narrow saw which will allow itself to be placed under the lower turbinal body and then turned horizontally toward the septum. In all cases it is the aim to remove as little of the edge of the inferior as is consistent with the restoration of sufficient breathing space. The cut should be so directed as to remove more of the posterior end than of the anterior. After the bone has been sawed through the remaining tissues should be divided with nasal scissors. It is advisable to avoid packing the nose after the operation except in cases of severe hemorrhage and the patient should be kept at rest and under observation for the 2 days following. [G.B.W.]

2.—Farlo reports a case of ozena which was apparently cured after treatment had been directed toward the sphenoidal sinus. [G.B.W.]

3.—Stinson says that the prognosis of congenital hernia of the umbilical cord is very grave, no matter what treatment is adopted, but far better results can be obtained by operating than by an expectant plan of treatment. In the ordinary umbilical hernia of infants and children, mechanical appliances will generally suffice to effect a cure, but when this fails a radical operation is indicated. Stinson proposes the following method as a radical operation for the cure of umbilical hernia in adults: An oval incision is made around the umbilicus and the sac opened laterally. The steps then consist in the removal of the excess skin, the umbilicus, the sac and the excess of serosa extending from the sac to the parietal peritoneum, the separation of all adhesions of the parietal peritoneum, the excision of protruding omentum and all omentum that can be withdrawn from the abdominal cavity by moderate traction. The hernial rings are cleared of all fat, glands and adhesions, but the layers forming the abdominal walls must not be excised too freely, only the edges should be trimmed away. The peritoneum and the transversalis are united with 2 continuous sutures of chromicized catgut. The edges of the lines alba and linea semilunaris and the sheaths of the recti muscles are united in 2 layers with continuous sutures of heavy chromicized catgut. If much tension is required to bring the edges together one or both recti muscles may be slid over to fill in the gap. The skin is closed with a subcuticular suture. [G.B.W.]

5.—Aldrich reports two cases in which piperazin had been used in the treatment of nephrolithiasis with signal benefit. The first patient was a man, aged 36 years, who drank more liquor than was good for him. He was attacked by a severe pain during the night. After the use of morphin he had some rest, but in the morning he had retention of urine. This was the first severe attack of renal calculus, but the patient had noticed uric-acid sand in the urine and had had pains in the loin. Twenty grains of piperazin dissolved in a quart of water was given daily for 16 days when the pain in the loin disappeared and he began to have vesical symptoms which were due to the presence of a calculus. The continued use of piperazin resulted in the passage of the stone. The second patient was a woman, aged 30 years, who had had symptoms of renal calculus, including cells from the kidney and ureter, free blood, albumin, and large quantities of uric-acid sand in the urine. She suddenly had hemorrhages from the urinary tract, which were repeated, often 4 or 5 per week. After 6 months' treatment by potassium and lithium salts, the patient was given 25 grains of piperazin in 5 pints of water daily for 7 months. The drug had to be temporarily stopped 4 or 5 times on account of vesical irritation. But the condition was much benefited in 8 weeks. [J.M.S.]

6.—Vaughan gives the following diseased conditions occurring in 31 cases of syphilitic optic-nerve and

retinal disease, coming under his observation: Primary optic neuritis, 1 case; retrobulbar neuritis, 1 case; papillitis, 2 cases; neuroretinitis, 3 cases; retinitis, 3 cases; chorio-retinitis, 2 cases; neuritic atrophy, 3 cases; genuine atrophy, 5 cases; tabetic atrophy, 11 cases. He also goes over considerable of the literature on the subject. [G.B.W.]

Medical Record.

September 29, 1900. [Vol. 58, No. 13.]

1. Some Personal Observations on the Effects of Intrapleural Injections of Nitrogen Gas in Tuberculosis. HENRY P. LOOMIS.
2. Electricity in Gynecology and the Present Reluctance of Gynecologists to use Electricity. ROBERT NEWMAN.
3. A Cure of a Case of Hypertrophic Alcoholic Cirrhosis of the Liver, with Remarks. M. LUZZATTO.
4. The Cooperation of the Medical Profession of the United States with the National Confederation of State Medical Examining and Licensing Boards, in Establishing Interstate Reciprocity for the License to Practise Medicine. ENIL AMBERG.
5. Treatment of Fractured Patella. WILLIAM B. TRIMBLE.

1.—Loomis considers injection of **nitrogen** extremely valuable as a **treatment for pulmonary hemorrhage**, and has never seen it fail in the 8 cases so treated. Ten other cases were treated for the effects on the lungs. The physical signs showed practically no change excepting that pleurisy was controlled at once, but there was a decided improvement in the general condition in nearly all, and the cough usually improved. Loomis has seen no bad results and believes that the treatment should be tested further and that it has come to stay. Injections failed in 8 cases owing to adhesions. [D.L.E.]

2.—Newman makes a strong plea for the increased use of **electricity in gynecology**, and for a more thorough study of electrotherapeutics. He has used electric treatment with great success in many uterine and pelvic troubles, such as amenorrhea, dysmenorrhea, and other menstrual disorders; in procidentia and subinvolution of the uterus, and in many forms of inflammation of uterus and appendages; stricture of urethra, bladder, and rectum, etc. In some cases of complete prolapse, a high-tension current caused contraction and diminished the size of the organ so that it was pulled back to its normal position without even the use of the hand, solely by the action of a continuous current. In many instances electrolysis has been used, thereby absorbing pathologic formations and even causing the reabsorption of fibroids; but it should never be used for peritoneal fibroids. Electrolysis applied with a mild current will cause absorption only, while a strong current will burn, cauterize, and even destroy tissues. Hence the writer always advocates a mild current, by which is understood a strength which is tolerated by the patient without being painful. The art in applying electrolysis successfully in gynecology consists in: (1) Using the correct strength of the galvanic current; (2) applying the poles at the right place; (3) selecting the size and material of the electrodes; and (4) timing the duration and intervals of the seances. Applying the correct pole in the right place means particularly using the positive pole for stopping hemorrhages, while the negative pole will absorb the fibroid tissues. Basing his conclusions on his own experiences and reports in literature, he thinks better results are obtained from treatment by electricity than by other means, and the reluctance of gynecologists to use or recommend it has not been explained. [W.K.]

3.—Luzzatto records the case of a man of 55, who had **cirrhosis of the liver**, with marked ascites, the origin being in alcoholism and malaria. The use of large amounts of milk with a short course of **potassium iodid** and diuretics caused free flow of urine, the ascites and other symptoms improved and the man gradually became apparently quite well, and now, 5 years later, seems in good health and is able to do a normal amount of work. [D.L.E.]

5.—Trimble discusses the various methods of treatment which have been practised for **fractured patella**. Fibrous or ligamentous union is the best we can expect from non-operative treatment, and this will in time stretch to such a degree that stumbling is produced, thereby frequently re-

sulting in accident. In most cases, when rigid asepsis can be observed, the wire-suture method is decidedly the best form of treatment. Trimble reports 3 cases in which he did the operation. [M.B.T.]

Medical News.

2. Some Studies in Metabolism in Chronic Nutritional Disease. G. W. McCASKEY.
3. The Art of Keeping Cool, with Special Reference to the Proper Use of Water. RALPH WAIT PARSONS.
4. The Dose of Potassium Iodid, with Reference to its Untoward Effects upon the Upper Respiratory Tract. LEWIS S. SOMERS.

1.—Guthrie describes some of the **famous quacks** of antiquity and modern days. Among these are Mesmer, Perkins, Cagliostro, Thomson, Schlatter, Dowie, and finally, Mrs. Eddy, to whose subject, Christian Science, both from the religious and medical standpoint, he devotes considerable space. He claims that many of the sects would be abolished if their professors were obliged to take the regular State examinations before being allowed to practise. [J.B.]

2.—McCaskey believes that the urine furnishes a convenient, accessible, and faithful index of the chemic processes going on within the body that we designate by the common term "**metabolism**." He takes up the principal constituents in detail. He believes that when there is an excess of urea, we should consider metabolism as excessive; in cases deficient of urea or hypozoturia, it is necessary to employ forced feeding. Uric acid varies very considerably. He does not believe that it bears any close relation to the number of leukocytes, as he has observed independent variations between it and a number of leukocytes in a case of myelogenous leukemia. The xanthin bases and other of the rarer substances are not sufficiently understood to render them available for clinical purposes. [J.S.]

3.—Parsons believes that water is of great value for the purpose of keeping cool in warm weather. It should be used internally and in the form of baths, the latter being more efficient if the water is dashed upon the skin. Cold baths render people less susceptible to atmospheric changes. [J.S.]

5.—Summers calls attention to the fact that in some cases small doses of **iodin** produce **iodism**, while in others, large doses may be taken without effect. He reports a case in which a man took 240 grains of iodine 3 times a day for 3 days for the purpose of curing rheumatism, and developed no unpleasant symptoms. He does not believe that tolerance of large doses indicates specific infection. In general the amount of the drug administered in any case should be determined by the effect produced upon the diseased process. Many patients appear to have a maximum iodine point, and if more than this is given, iodism occurs. The simultaneous administration of arsenic and belladonna often prevents the appearance of iodism. [J.S.]

1. A Study of the X-Ray Plates of 140 Cases of Fracture of the Lower End of the Radius. E. A. CODMAN.
2. Traumatic Joints. HOMER GAGE.
3. A Critical Review of 30 Cases of Pyosalpinx. G. S. WHITESIDE and W. J. WALTON.
4. Post-Operative Hematemesis. KENELM WINSLOW.

1.—Codman reports a study of skiagrams of 140 **fractures of lower end of the radius**, treated at the Massachusetts General Hospital in the last 4 years. It was found that these cases could be separated into 10 or more distinct types according to the lines of cleavage and the directions of the displacements. He emphasizes the fact that true Colles' fracture formed but 46% of 140 cases, and that a knowledge of the position of the fragments is necessary for intelligent treatment. The application of padding and splints should vary according to the displacement shown in the skiagram and if the x-ray shows that marked deformity is still present

after the splints have been applied, ether should be given, and another energetic attempt at reduction made. Concomitant fracture of the ulnar styloid occurred in at least 62% of 140 cases, and if 39 cases in which this process was obscure in the skiagram are deducted, fracture occurred in 86%. In true Colles' fracture pressure over the anterior edge of the upper fragment should be avoided and cross traction should be used to correct the radial displacement of the lower fragment. Statistics of the result of Colles' fracture are not of value unless the pathology of each case is determined by a skiagram. [M.B.T.]

2.—Gage believes that all injuries to joints accompanied by loss of function are always attended by more or less laceration of the tissues in or about the joint. Delays in restoration of function are due in most instances not to any complicating diathesis, but to changes incident to repair of these lacerations and their effects. Such delays are best avoided by an early resort to massage and active or passive motions, and are favored by too long a continuance of rest and fixation. He makes the distinction between carefully applied massage and indiscriminate rubbing. When delays in restoration of function have occurred they are best overcome by more vigorous and persistent manipulation, supplemented by the application of heat or such other agents as may best stimulate the local circulation and favor the elasticity of the tissues. [M.B.T.]

3.—Whiteside presents a review of 30 cases of pyosalpinx in which the mortality was 1 death from fecal fistula, 1 from general tuberculous infection 1½ years subsequent to operation, and 2 from general streptococcus peritonitis. It seems clear from a review of these cases that the gonococcus cannot be proved to be the cause directly or remotely in as large a number of instances as is generally supposed. Other organisms, not found recorded as being responsible for such a condition, have been demonstrated to be the only living organisms present in a considerable number of cases. Among these may be mentioned *Bacillus mesentericus*, *Pneumococcus lanceolatus*, *Bacillus tetragenus*, and 2 organisms more commonly demonstrated by observers—*Bacillus coli communis* and *Streptococcus pyogenes*. It cannot be proved that through the action of the gonococcus the normal integrity of these tissues has been impaired, and so made a suitable soil for the development of these other bacteria. Neither can this theory be disproved by such purely negative results as obtained by the writer. Seventy-five per cent. of these patients were married or widows. In 50% the urine was normal, and 50% showed pus, blood, and casts. Leukocytosis was present in all cases in which a blood-count was made, the lowest count being 8,800, and the highest, 32,000. Apparently the amount of leukocytosis was without regard to the organism present, or the amount of pus found at the operation. The temperature was elevated in all cases. In 17, it ranged from 99° to 101°. In the remaining cases an almost equal number were above and below these figures. The temperature apparently bears no constant relation to the leukocytosis present. Of the pulse, it may be said in general that it was not far from 100 in the majority of cases, and that no direct or definite relation can be established between the rate of the pulse and the leukocytosis. Sixty per cent. of the 30 cases showed acute symptoms referable to the pelvis for more than a year. The remaining 40% were all cases of less than 1 month's standing; of these, 4 were mixed pyogenic infections. The exact morphology of the bacteria in these could not be determined. One contained the pneumococcus in pure culture; 1, *Micrococcus tetragenus*; 2, the gonococcus; and 2 were bacteriologically negative. One other case of virulent streptococcus infection was probably acute, but no record of the duration of the attack was obtained before her death. From this series of cases the following conclusions are drawn: The mortality of the operation, taken as a whole, is 16%. The greatest dangers to be apprehended are in streptococcus infections from peritonitis, in all drained cases of fecal fistula; in tuberculous cases, from extension of the disease to other organs. [W.K.]

4.—Winslow reports a case of postoperative hematemesis occurring in a woman of 65 who was operated upon for umbilical hernia. The hernia had existed for about 20 years; it had been incarcerated at times, but reduction had spontaneously occurred. The reduction was probably only partial. The patient was first seen after a history of colic and vomiting for the previous 6 hours, with unsuccessful

attempts at reduction of the hernia by taxis, ice-bag, etc. An endeavor under ether did not prove any more satisfactory, and the operation for radical cure was performed. The patient did well for 3 days but then began to vomit blood in small quantities and died soon after. At the necropsy considerable dark, clotted blood was found in the stomach and small intestines, but no lesion of the mucous membrane or other cause for the hematemesis was discovered on careful search. 5.—Class states that Baginsky and Sommerfeld have recently reported the discovery of a *microorganism* which is the probable cause of scarlet fever and which is the same germ discovered by him and described some time ago in American journals. He brings forth evidence to show that the germ named by him *Diplococcus scarlatinae* was not described before his description of it; that it is constantly present in scarlet fever; that it is a pathogenic organism, producing fever in animals; and that the pathologic changes produced by it resemble those of scarlet fever, etc. It must be admitted that the diplococcus of scarlatina fulfils all of Koch's laws, and is therefore entitled to some consideration at the hands of those engaged in a search for the solution of the etiology of scarlatina. 6. Personal Reminiscences Associated with the Progress of Gynecology. THOMAS ADDIS EMMET.

1.—Skene, after a careful study of a number of cases reported and coming under his own observation, classifies myofibromas of the uterus in relation to childbearing as follows: 1. Submucous tumors, large or small, cause sterility as a rule (he has seen only one exception). 2. Small subperitoneal myofibromas which do not always cause sterility nor complicate childbearing to a very dangerous degree. 3. Interstitial tumors, unless so small that they cannot be detected, and large subperitoneal tumors closely connected with the muscular tissue of the uterus, do not cause sterility in all cases, but they are most dangerous complications of gestation, because they predispose to miscarriage and render delivery always difficult, often impossible, and always exceedingly dangerous. Therefore, in considering treatment, the first class may be left out of account; the second class requires attention in the first months of gestation in order to keep the uterus in position and aid in its escape from the pelvis up to the abdominal cavity, and finally they may require help in delivery and special protection from postpartum hemorrhage. The third class demand hysterectomy as the surest means of saving them. The hysterectomy

should be performed as soon as the first indication of miscarriage occurs, which is almost invariably after the death of the fetus. [W.K.]

2.—Ferguson divides the methods of **intestinal anastomosis** into three classes: Intraintestinal, in which the severed bowels are coapted and held together by means of plates, buttons, bobbins, couplers, rings, cones, or sutures; extra-intestinal, in which the continuity of the bowel is restored or a new passage for alimentary contents is obtained by the aid of continuing, interrupting or interlocking sutures, which are applied from the peritoneal surface of the bowel; combination method, in which both intraintestinal and extra-intestinal means are utilized. Any inaccuracy in the intestinal suture is followed by leakage, septic peritonitis and death. Too stout a needle, too coarse a thread, or too much space between the sutures may all be causes of failure. It has been established by Halsted that for the stitches to be always safe, the firm fibrous submucosa must be properly grasped by the needle, and then the threads can be tightly tied without the danger of tearing. For successful enterorrhaphy special attention should be paid to rapidity and accuracy, to soiling the peritoneum, and to leakage. In order to insert stitches rapidly, accurately, and so efficiently as to prevent leakage, the bowel must be firmly and evenly held. For this purpose many instruments have been devised. Grant has invented an enterotome for lateral anastomosis which has high merit. Laplace uses forceps with rings at the end to grasp the intestine while stitching, and Halsted uses inflatable rubber cylinders. Ferguson presents bowel clamps, the blades covered with rubber, devised to be applied to the bowel to prevent the escape of the contents while operating, the pressure being controlled by screws at each end; also a combined enterotome clamp which is employed in the extraintestinal method of suturing. It is easily and rapidly placed and holds the parts to be sutured firmly and securely together while the sutures are applied except to the small hole where the blades enter; the stitches are inserted first and the intestinal walls are cut afterward. The pressure of the clamp on the bloodvessels of the mucous membrane for several minutes while sewing is being done, lessens the tendency to hemorrhage, and the new passage made between the bowels may be of any size necessary, thus preventing the possibility of stricture formation. [W.K.]

3.—As statistics apparently indicate that **cancer** is on the increase and is more characteristic of the highly civilized classes, Ford believes this should revive our interest in the study of this dread disease. The uterus comes next to the breast and stomach as the favorite seat of cancer, and the first 5 years after the menopause is the time it is most frequently encountered. Sarcoma is much more commonly met with in young women. When it is once proved that a growth, however small, is cancerous, a total extirpation of the organ in which it is lodged is the only safe rule to follow. Small fibroid tumors in the wall of the uterus that begin to bleed badly also demand a hysterectomy. The hope of the future undoubtedly lies in the investigations which are being carried on in laboratories all over the world where experiments may ultimately bring forward some lymph that shall cure without the use of the knife. At present, however, the use of the knife is so much more humane than any other management that it must be the only resource in operable cases. At least one-half of the cases which are seen early and are submitted to radical operation recover and remain well for an indefinite number of years. Of the remainder, half, perhaps, live from 2 to 4 years, while all the rest are saved infinite suffering, and life is prolonged from months to years. The recurrence of cancer after a total hysterectomy is very frequently found in the lungs or liver, a comparatively short and painless illness following. [W.K.]

4.—Dorland reviews the literature of **placental transmission** of drugs and specific diseases, and derives therefrom some very suggestive if not conclusive, arguments. 1. While many drugs may be administered to the mother without any noticeable effect upon the fetus, there are certain substances which show a special tendency to traverse the placenta, and, entering the fetoplacental circulation, exert a positive influence for good or evil according to the condition which may be present in the given instance. 2. Maternal medication, therefore, is indicated in certain conditions, either in order to prevent the development of a simi-

lar condition in the fetus, or to counteract the effect of germs and their toxin already introduced into the fetal economy. 3. The drugs which have been found to affect the fetus in utero are notably opium, mercury, copper, lead, arsenic, and the iodids. In appropriate doses they may be administered to the mothers in suitable pathologic conditions with beneficial results to both mother and child. 4. Any morbid influence acting upon the mother either acutely, as in the case of the exanthems, or more slowly, as in tuberculous and specific infection, will react deleteriously upon the product of conception, and either destroy it through its overwhelming toxic action, or render it feeble and less resistant to subsequent and postnatal invasion, or the disease will run an atypical course in utero with or without apparent vestiges at birth. 5. The entrance into the fetal structure is accomplished through the agency of the fetoplacental circulation. It is probable that access is gained through bacterial action, the germs rendering the placental villi less resistant to invasion, whereby both the microbes and their toxins pass the natural barrier at the choriodecidual junction. 6. As a rule, the infectious diseases do not manifest their characteristic visceral lesions in the fetus, probably because of the passivity of these organs during antenatal existence. The germs, however, may be detected in large numbers by bacteriologic and microscopic examination. [W.K.]

5.—Goldspohn believes that though **retroversions** and **retroversio-flexions** invite disorders of a more serious nature, they do not cause death; and while they do embarrass conception and gestation, they do not interfere with labor itself. Therefore, all surgical or other measures that are chosen for their correction must not have any pronounced rate of mortality, must not create conditions which may disturb normal gestation or obstruct natural labor, and they must not disarrange the normal anatomy or disturb the functions of other equally important organs. In the surgical treatment of these displacements it is of prime importance to make a clear distinction between females who retain no probable capacity for conception and those who do. And surgical procedures, such as a firm and direct fixation of the fundus to the vagina or to the abdominal wall, may be very suitable in the former class, but should be totally avoided in the latter. The objection to the use of the simple Alexander operation as a remedy for uterine displacements in women capable of reproduction, is that it is not a durable remedy, that recurrence of the displacement so often takes place, especially after parturition. Goldspohn thinks that in such cases the only satisfactory operation is a bilateral inguinal celiotomy and shortening of the round ligaments via the dilated inguinal rings, and he gives a brief description of the technic. From September, 1893, to March, 1900, he has performed this operation in 106 cases, always in connection with some auxiliary operation and there has been no death due to the operation. Nine months ago he made a careful review of the present status of 49 of these and was personally informed of the condition of 25 others, and in no case was there a recurrence of the displacement nor a fully developed hernia. Thus his own experience, as well as the testimony of Edebohls, Burrage and others confirms his postulate that shortening the round ligaments via the inguinal canals, if thoroughly done, is so far the only operation that has been proved not only not to hinder gestation and labor, but also not to permit a recurrence of the displacement afterwards; because such comparatively good ultimate results have not been shown nor can they be shown by the advocates of any other operation. intestine was pushed into the abdominal cavity there was a gush of blood as thick as a little finger, which was checked by freely flushing the uterus with sterile hot water, which was at hand. The woman was now so pulseless that no further operation was performed, but she was removed to a hospital, having a temperature below 96° on her arrival there. The treatment in the hospital was simply sustaining and stimulating, with hot bichlorid vaginal douches. She was discharged well about a month after her admission. She menstruated normally a month later and regularly subsequently for 3 months, when she again became pregnant. The special points of interest are: The want of evidence of rupture at time of labor; the length of time intervening between the occurrence of the rupture and the manifest evidence of sepsis; and the rapidity with which she recovered after the removal of the offending cause, the gut. [W.K.]

5.—Kolischer discusses those **traumatisms of the bladder and urethra** occurring during labor which are least known, because they do not produce any external wounds. The urethra gets injured during labor by being directly bruised or by being bent through the descent of the fetal skull. All the urethral lesions caused by squeezing are most likely to occur in cases of simple flat pelvis. Inasmuch as the anterior fornix postpartum does not appreciably retreat, ischuria sets in, which has to be relieved by inserting a catheter, which procedure has to be controlled by placing one finger in the vagina. The urethra is straightened out and the free passage of urine becomes secured by repeated catheterism. Another variety of urethral incontinence occurs if the lower urethral wall only is carried downward; this happens most likely in forcible forceps operations, whereby the vaginal fornix is very rapidly dragged down; whereby the urethra becomes funnel-shaped, the larger aperture looking toward the bladder. The posterior part of the urethra being thus distracted, gives rise to absolute incontinence. The recognition of this condition is particularly important, because prompt intervention soon restores normal functions, while overlooking it and indifference renders the incontinence permanent. The urethral sphincter very rapidly loses its functional power definitely and does not regain it, having been inactive for a certain time. After having established the diagnosis by ascertaining the lowering of the anterior fornix and by the absence of any resistance at the internal orifice when introducing a sound, one has to replace the fornix and has to support the posterior urethra by inserting a hard annular pessary into the vagina. The sphincter muscle recovers now rapidly, and the pessary is removed after the involution of the genitals has made sufficient progress. [W.K.]

6.—Atlee reviews several cases of **chronic inversion of uterus** and its treatment by Harris who says, "The condition of the uterus must have much to do with the final success or failure of operative measures for replacement. It is evident that there are favorable and impossible periods for the effort of reposition. The favorable time would appear to be: (1) Immediately after the accident, and before the cervix has become contracted; (2) at the end of 7 or 8 weeks, when involution has altered the density of the organ; and (3) when a succession of hemorrhages has rendered the patient thin, pale and anemic, and her tissues soft and yielding. The diagnosis of uncomplicated version is not difficult, but the problem is far different when the inversion is attended with a polypus or there is a large polypus filling the vagina from an inverted womb. It is impossible to pass the treatment of chronic inversion of the uterus without mentioning the use of the colpeurynter in these cases, and though it has been accused of being unbearable in many cases, and of having caused sepsis, there always remains the possibility of its having been used in ill-advised cases and in an improper manner. Most failures to reduce the inverted uterus by elastic pressure are attributable to the want of judicious adaptation of the force, and lack of perseverance in its use. The attempt should not be to reduce the organ in a short time, but to overcome its rigidity by long-continued and gentle pressure. Atlee in this paper on chronic inversion of the uterus, endeavors to show: (1) That there are times more favorable than others for its replacement; (2) that for each individual case some one particular method will be most likely to be successful; and (3) to demonstrate the great difficulties which may be encountered in certain conditions, to the establishment of a satisfactory diagnosis,

and to bring into review some of the procedures which, in the hands of the most experienced men, have overcome them. [W.K.]

7.—Gordon from his experience in **treatment of gallstones** has reached the following conclusions: 1. Operations should be performed after it is well established, by repeated attacks, that gallstones are present. 2. Gallstones may be present in the bladder for years without giving colic, but they are a cause of more or less digestive disturbance and impairment of the general health. 3. From his experience in 1 or 2 cases, and from reports from the Maine General and other hospitals, he is satisfied that many cases are better treated at the time of operation, by closing the bladder, dropping it back into the cavity, and closing the abdominal wound. 4. Cases treated by drainage are, in many instances, slow to recover, and liable to be left with biliary fistula for a long time. 5. Great care should be used to cleanse the bladder before closing it, rendering it as nearly aseptic as possible. 6. While cases of recurrence of gallstones may follow operation, he believes they are no more liable to return after closing than after drainage. [W.K.]

The Journal of Mental and Nervous Diseases.

1. Autopsy in a Case of Adiposis Dolorosa, with Microscopic Examination. F. X. DERCUM.
2. Imperative Ideas in the Sane and their Management. EDWARD B. ANGELL.
3. Christian Pseudo-Science and Psychiatry. SMITH BAKER.
4. A Case of Monocular Hysterical Amaurosis in a Girl, 11 Years of Age. C. A. VEASEY.
5. On the Use of a New and Efficient Hypnotic in the Treatment of the Insane; Chloretone. J. PERCY WADE.

1.—Dercum reports the results of a necropsy upon the case of **adiposis dolorosa**, originally reported by him in 1888. Briefly, the patient, at the time of death, a woman of 63, had noticed, at about the age of 49, some enlargement of the arms, which became deformed by the development of huge, subcutaneous, nodular masses. There was slight diminution of cutaneous sensibility in various regions. Subsequently, the swelling became more extensive, although even at the time of death the hands, feet, and face remained uninvolved. There was considerable tenderness and occasionally subcutaneous pain. The skin was dry, and occasionally the temperature was subnormal. At necropsy, the subcutaneous masses were found to be ordinary fat, and nerves passing through this tissue showed diminution in fibers and slight sclerosis. There was slight degeneration in the column of Goll, in the upper thoracic and cervical regions of the spinal cord; otherwise, the nervous system, with the exception of slight increase of pigment in the nerve-cells, was normal. The pituitary body was normal, the thyroid glands were small, but upon examination showed signs of active proliferation, and excess of secretion. Dercum admits that it is very difficult to explain the nature of this case. He notes that in 2 previous cases the thyroid glands macroscopically showed evidence of change. [J.S.]

2.—Angell believes that we should sharply distinguish between **imperative ideas** which are morbid suggestions that the patient wishes to resist but cannot, and **fixed ideas** with which psychical reaction is in harmony. An imperative idea requires a center that suddenly and isolatedly enters into function, its action being not required by the mental needs of the moment, while at the same time there is temporary impotence of the will to remove an obsession. The treatment of these conditions involves of course the removal of any underlying physical condition, either in the form of exhaustion or functional perversion. This, however, does not always relieve the mind. In order to secure the latter it is necessary to occupy the patient, to give him an abundant diversity of activity and interest, and in some cases to use hypnotism. This should not be regarded as having a tendency to produce miraculous effects, but rather should be continued for a long time at decreasing intervals even when apparent cure has been obtained. In addition, mental gymnastics may be employed with advantage. [J.S.]

3.—Baker has observed that the parents of many children subject to nervous derangements have suffered from some

form of stress or privation before the child was born. In the treatment of these conditions, he prefers **intellectual development to hypnotism**. In discussion of this paper, Mitchell reported an interesting case in which a patient, with an imperative concept for repeating certain actions, was practically cured by being pinched on each occasion by a relative. Mitchell expresses himself as convinced that hypnotism is practically useless in the treatment of nervous disease. Sachs mentioned that in his own case when a boy he had a dread of the number 2 or multiples of it. [J.S.]

4.—Veasey reports a case of **hysteric amaurosis** occurring in the left eye of a girl of 11. When first examined there was no perception in this eye even to concentrated light, but subsequently it was found that she could see normally. The color fields were contracted and inverted, and there was anesthesia over the conjunctiva of the left eye. Vision was restored so soon as the child was convinced that she could see with the eye. [J.S.]

5.—Wade is enthusiastic over the value of **chloretone** in the treatment of the insane. He finds that it has no bad effect upon respiration or circulation. It is a moderate general anesthetic, a local anesthetic, and does not disturb the digestive system. The dose required is considerably greater than has been ordinarily recommended, at least 15 grains, and the average dose that he administered was 35 grains. It seems to have some curative effect in cases of mania and of agitated melancholia. He reports 18 cases of various conditions in which it was used with advantage. [J.S.]

September, 1900. [Vol. xxvii, No. 9.]

1. The Anatomic-Cytologic Relationship of the Neuron to Disease of the Nervous System. LEWELLYS F. BARKER.
2. The Pathologic Changes in the Neuron in Nervous Disease. WILLIAM G. SPILLER.
3. How Does the Neuron Doctrine Affect the Conception of Nervous Disease? B. SACHS.

1.—Barker discusses the **histology of the nervous system**, particularly in regard to the "nerve unit" or neuron. He prefers to apply the term perikaryon to the "nerve-cell" proper, as this latter is so often applied wrongly to the whole neuron by many textbooks. Nerve-cells differ from other tissue-cells in their variability of appearance in different parts of the system, making their positions easily recognized. Like other tissue-cells, there is a questionable connection between the elements of the nervous system in 3 ways: The terminal expansion of an axon around a perikaryon; close apposition and a possible fusion of the terminal fibrils of axones with dendrites and perikaryons; and the passage of fine fibrils from one neuron to another. A history is given of the development of our present knowledge of the neuron and its 3 divisions—the perikaryon, axons, and dendrites, and the important part played in these discoveries by neuropathology by the study of degenerative changes. After the establishment of the neuron doctrine came accessory theories, important among which are: The complete independence of each nerve-unit, except by contiguity; the theory of amoeboid movements of the processes; and various theories concerning the structure of the conducting portion of the neuron. Most of the objections raised against the neuron doctrine have been urged really more against one of these accessory theories. Three methods of communication between the elements have been established: Occasional anastomoses between dendrites; intimate protoplasmic relations between terminals and collaterals of one axon with perikaryons and dendrites of other elements; and fibrillary communications from one neuron to another. The author mentions the investigations of several men, showing that the conducting substance of the neuron is the fibrillary structure which is seen in the perikaryon, dendrites, and axons, and the penetration of these fibrils into muscle, glandular, and other cells. Bethe has announced that the fibrils entering the cell-body by dendrites may be traced to pass out through other dendrites as well as the axon. In conclusion, the author does not state an opinion as to the contact theories, but advises precision in the use of names applied to the 3 parts of the neuron. [J.S.]

2.—Spiller says that if an axon is cut or affected by disease, the cell-body undergoes alterations, the intensity of

which depends probably in the nearness to it of the seat of injury. These changes may consist in chromatolysis, deformity or displacement of the nucleus, or complete disappearance of the cell-body. They are probably not rapid, especially if the injury is near the distal end of the axon. In chronic diseases affecting the axis cylinder, no changes may be seen in the cell-body, particularly if the lesion is far distant from it. In such cases the cell-body may have recovered. **Chromatolysis** is, therefore, of doubtful value to show degeneration. A case of hip-joint amputation is cited with death 5 days after the operation; the cells in the anterior horn in that side stained badly and showed chromatolysis, while those on the other side were normal. All parts of the neuron are not affected promptly in disease of the cell-body, showing that while it lives and is not too much altered, it still has some effect on the life of the axon. The latter is dependent on the cell body to appropriate nourishment brought to it by its blood-supply at its distal parts, but if this blood-supply be cut off, that portion of it will die. It is possible for certain poisons to affect entire neurons. These remarks apply to the peripheral motor neurons, but the same changes may be observed in the central ones. In the peripheral sensory neurons, if the peripheral process of the axon be destroyed, degenerative changes are seen in the cell-bodies of the spinal ganglia, but if the injury be to the central process, no such changes will be found. This has been noted in cases of tabes. When focal lesions occur in one set of neurons causing secondary degenerations, it is not frequent to have tertiary degenerative changes in another set, although cases are reported, as in some of hemiplegia with secondary degeneration of the pyramidal tract, the cells of the anterior horns were found to show alterations. The author prefers the term "tertiary atrophy" in such cases. There is no evidence that disease of a sensory neuron results from that of a motor neuron. Degenerations may extend from one neuron to another, but not frequently enough to disprove the neuron theory. [J.S.]

3.—Sachs does not think the **neuron doctrine** has been of as much assistance in the study of the causation of nervous diseases as was expected of it at first, although it has assisted in a better classification of such disorders, and in clearing up many doubtful facts. It is of assistance in the investigation of toxic diseases. In tabes the disease is in the sensory neuron and the axon is first affected. The ganglion cell could not be altered without this primary change, bringing about alterations in the stimuli carried to the cell-body. Syphilitic poisons affect chiefly the sensory neurons, while other poisons usually pick out the motor ones. The doctrine has given us a "better understanding of the spinal form of progressive muscular atrophy and its relations to progressive bulbar palsy and to amyotrophic lateral sclerosis." In the first 2 we have primary degeneration in the direct motor neuron, while in the latter there is the same degeneration in the direct motor neuron as well. Conflicting views on the causes of the changes in progressive muscular atrophies and dystrophies may be reconciled somewhat by the neuron theory. If the view is accepted that disease of one neuron may affect the neighboring part of another—"that disease affects parts functionally if not structurally related"—the combined sclerosis of the cord are more readily understood. The neuron theory cannot be applied to the interpretation of mental or functional disease. [J.S.]

3.—" " " " " p. 999.

4.—Hand reports the case of a 4-months-old, breastfed

infant, that was taken ill with symptoms of intestinal colic. When first seen the temperature was 101° F., pulse 150, and there was a tumor in the line of the descending colon. Floating spleen and kidney were excluded and a diagnosis of **intussusception** was made. Five drops of paregoric were at once given by mouth, a wet flaxseed poultice was applied, and in an hour an **injection** was given. While the left hand manipulated the tumor, during the injection, it suddenly disappeared. The bowels moved 5 hours after the injection. Six days after the beginning of the illness and just after nursing the patient began to vomit, had diarrhea, a temperature of 102°, and presented an indistinct, tender mass in the location of the tumor. Under paregoric and poultices, followed by lime water and cinnamon water, and, later, by bismuth subnitrate, the condition subsided. The case shows that intussusception is by no means cured when reduction is accomplished; but that the **secondary enteritis** may cause many anxious moments. [J.M.S.]

2.—Seibert claims that patients fed on milk during an attack of typhoid fever (a specific form of enteritis) are but little better off at present than former patients were during an attack of summer-complaint, with milk and opium-mixtures in their intestines. If the majority of typhoid-fever patients fed on milk were not adults, but children, the percentage of typhoid-fever mortality at present would equal that of gastroenteritis of former years. He tried **feeding typhoid-fever patients** on a fluid diet, not including milk; at first strained soups made of meat-broths, containing oatmeal, barley, rice, and peas, well spiced with salt and pepper; and later lentil soup and the yolk of a fresh egg added to the oatmeal; rice, and barley soups were given so as to allow an adult $\frac{1}{2}$ pint of 2 kinds of soup alternately every 3 hours, and smaller quantities to children according to age. Five meals in all were given during the day. In addition, every typhoid patient was given from 2 to 4 **rectal enemas** of plain, warm water daily. As a result of this treatment, delirium, headache, insomnia, nausea, vomiting, and tympanites usually disappeared within 48 hours. Tympanites, nausea, and vomiting did not develop in any patient, even when pneumonia was present. The fur on the tongue disappeared within a few days. The appetite came frequently on the fourth day of treatment, even when the thermometer registered 102° to 103° F. Excessive diarrhea (15 to 25 stools daily) invariably disappeared within the first week of treatment. In all uncomplicated cases the temperature began to decline within 24 to 48 hours after the beginning of treatment, and invariably reached the normal within 10 to 12 days. In cases complicated by pneumonia, nephritis, or phlebitis, when treatment began the temperature usually remained in accord with the inflammatory conditions found until these also disappeared, while the cerebral, gastric, and intestinal disturbances, excepting anorexia, usually subsided as rapidly as in the uncomplicated cases. Complications, when not present at the start, were very rare, and then usually developed within the first 2 days. Intestinal hemorrhage was noticed in 3 cases, none of which ended fatally, while perforation did not occur. [J.M.S.]

3.—Baines reports the case of a boy aged 2 years and 8 months, who died from **lead-poisoning**. The mother of the patient suffered 3 weeks before he was taken ill from a sharp attack of lead colic, and a brother, aged 5 years and 9 months, died from the same cause. The manner of absorption of the lead was unusual; for a week previous to the illness of the first child the meals had been cooked with firewood procured from staves of old barrels which had contained white lead, so that the fumes of lead not only entered into the food, but permeated the atmosphere of the house. The patient had never been ill until November 6, when he had a well-marked convulsion, lasting about 5 minutes. He recovered completely from this attack and was quite well until the

evening of the 19th, when he had 4 convulsions within a few hours. Each convulsion lasted from 3 to 6 minutes. The child was practically unconscious from the first convulsion, rousing slightly at intervals for a few moments; he had frequent attacks of vomiting, and his bowels for a few days were somewhat constipated. During the convulsions the face would first become flushed, the eyes would open wide, then become fixed and staring, the pupils were widely dilated. Then the eyes would roll about, the eyelids and the lips begin to twitch, and soon whole sets of muscles, of the face, the arms, the legs, and the body would become involved; every convulsion beginning above and extending downwards. During these attacks the patient gave vent to a peculiar grunting moan; there was no opisthotonus. A brother of the patient, aged 5 years and 9 months, for 3 or 4 days had severe pain in abdomen; the bowels were obstinately constipated, and these symptoms terminated in a convulsion of the entire body. Whilst awaiting admission to the hospital he had a series of 7 or 8 convulsions in 20 minutes. These attacks differed, some being general, some unilateral, mostly right side, and, as in the case of the first patient, resulted in semicoma. The 2 children lived for nearly the same time to an hour, about 3 days. Four ounces of urine from the second patient contained 4 mg. of lead. The convulsions were many, 95 on the first day and 18 during the night. Towards morning the convulsions ceased, but the patient gradually became weaker and died. Necropsy revealed nothing markedly abnormal. Bacteriologic examination resulted in the isolation from the brain and lung of a diplococcus that was fatal to mice. [J.M.S.]

4.—Cotton reports the case of a girl, aged 7 $\frac{1}{2}$ years, who had been active and apparently in good health until July 4, 1899, when she had an attack of measles, followed by bronchitis. She had never been well and strong since this illness. The cough persisted and she "seemed to take cold easily." In February, 1900, she had a severe attack of bronchitis and during this illness there was a daily afternoon rise of temperature, with profuse night-sweats. This latter symptom had been present for some weeks, but to a less marked degree. On March 16, after a very hard coughing spell, a ridge appeared over the right clavicle. The cough continued paroxysmal and frequent, and the gradual extension of this cushiony ridge in all directions occurred. There was no history of convulsions or edema. The urine had been scanty and turbid. The patient was held by her grandmother in a sitting posture, slightly bending forwards. The face presented a swollen appearance; the lower lids particularly were enormously distended. The skin had a peculiar, waxy color, the lips were somewhat cyanotic and the expression was anxious. Examination of the surface showed great distention about the neck and chest, completely obliterating the clavicular depressions, and extending downward over the trunk, especially in the dorsolumbar region along each side of the spine. Pressure elicited distinct crepitation and left no pitting. The child resisted all efforts to assume any other position than the one mentioned. Her attention was wholly bent upon securing air and repressing the frequently recurring cough. The respirations were shallow and rapid (50 per minute); the pulse was rapid and barely perceptible; the temperature was 102° F. Physical examination by percussion was difficult on account of hyperesthesia. It was possible, however, to make out hyperresonance over the greater portion of the chest. From the symptoms the diagnosis of **generalized subcutaneous emphysema** was made. During the 6 days of life, infiltration of the subcutaneous tissue extended, involving both upper and lower extremities with the exception of the palms of the hands and the soles of the feet; the skin became tense and shiny. The urine showed considerable amount of albumin. [J.M.S.]

5.—Herman reports the case of a boy, 11 years old, the oldest of 4 children. The child's mother is easily excited and is subject to attacks of unconsciousness. One other child is, according to the mother, "peculiar." When the patient was 4 years old he had an attack of scarlet fever; he has had no convulsions, but has had frequent headaches. The present illness began 8 weeks ago with eructations. This was followed in a few days by the **laryngeal attacks** that consist of a long deep inspiration, with a simultaneous spasm of the glottis, causing a sound similar to that of laryngismus stridulus, but much louder and shriller; they recur at intervals of from 10 to 15 minutes, and cease during sleep.

The frequency of the attacks is affected by surroundings; at home they are much more frequent than in other places. This is principally due to the familiarity of his surrounding, and possibly partly also to the impurity of the air in small, ill-ventilated rooms. In the presence of a number of strangers the attacks are much less frequent. For example, when riding in the cars, he is able to control the attacks, because the attention attracted by so peculiar a sound causes him to feel ashamed. The condition is considered by Herman to be **hysteric**. [J.M.S.]

8. A Case of Retroverted Gravid Uterus, with Remarks. G. R. FRASER.

1.—Gibson contributes a clinical lecture on the **persistence of the arterial duct and its diagnosis**. In consequence of the higher pressure of the blood in the aorta as compared with the pressure in the pulmonary artery, there must be a current from the former to the latter, in case the ductus arteriosus is patulous, and this stream will be almost continuous. The blood will flow with greatest velocity during and immediately after the ventricular systole, when the pressure in the aorta is at its highest. It must, therefore, be expected that the condition will be evidenced by a long murmur, beginning a little after the commencement of the first sound, filling up the short pause and continuing beyond the second sound. The murmur is almost invariably accompanied by a thrill. Both murmur and thrill are heard with maximum intensity in the second or third left interspace, just outside of or below the pulmonary area. The clinical and pathologic history of a fatal case is given. The condition may give rise to no symptoms and the diagnosis is based upon the physical signs alone. [J.M.S.]

2.—Smith makes a plea for the abandonment of the idea of **inflammation being a definite pathologic process** and lays stress instead upon the fact that it is a method by which nature rids the body of foreign matter and by which she replaces lost tissue. By abandoning the old idea the medical nomenclature would necessarily be changed—by the dropping of the affix "itis." He suggests in its place "osis," streptocosis then meaning an infection by the streptococcus; staphylocosis, an infection by the staphylococcus, etc. Pericardosis would indicate an infection of the pericardium and pericardial pneumocosis an infection of the pericardium by the pneumococcus. [J.M.S.]

3.—In considering the subject of the **therapeutics of disorders of the menstruation**, Jones subdivides it into three heads,—hygienic, medicinal, and operative. Under the first we include, in the treatment of suppression or absence of the catamenia, suitable gymnastic exercises, embracing a course of Swedish movements and massage. With this may be combined the external and internal use of galvanism or faradization. Cycling and other outdoor sports, when not overdone, are decidedly advantageous. Suitable hydropathic treatment at the various spas occupies a prominent place in menstrual therapeutics. In regard to internal medication, senecioin in 2 to 6 gr. doses is very valuable. It may be used alone or with hydrastis or with hydrastinine. The latter drug is useful in congestive and spasmodic dysmenorrhea, the more so if combined in the administration

with the bromids. An admirable combination that may be given in pill, while the dioxid is given in palatinoid, is that of dried iron sulphate, quinin, extract of nux vomica, and arsenious acid. Of the coaltar products for the pain of dysmenorrhea he believes antipyrin or phenalgin in combination to be the best. The vascular tonics, strophanthus and digitalis, are indispensable in those cases where there is cardiac irregularities, enfeebled action, mitral stenosis, etc. In regard to the third head, or surgical treatment, he believes that obvious or gross changes should, in the female genitalia, as elsewhere in the body, be dealt with on broad general principles. Useless and diseased parts should be removed, useful and healthy portions of organs preserved, and, with the comparatively slight risks involved in the modern operations of colpotomy and laparotomy, especially the former, there is no surgical excuse for procrastination in dealing with conditions that may sooner or later destroy not only an organ but a life. [W.K.]

4.—Affleck reports 5 cases of **beriberi** that occurred in adults and 1 case that occurred in a child. The adults were all seafaring men and in each case they had come from a tropical or a subtropical region. Each case presented the characteristic features of a peripheral neuritis and, in addition, the majority had more or less edema of the legs. In the case of the child there had been recurring attacks of vomiting, widespread paresis of the legs and arms, together with some edema. When the patient was seen there was evidence of a peripheral neuritis in the lower limb which gave rise to the steppage gait as well as to various sensory abnormalities. The patients rapidly improved by very simple treatment. Bacteriologic examination of the blood of 3 of the cases was negative. [J.M.S.]

5.—Bell considers **acute infantile intussusception**, giving a concise yet full review of the etiology and symptomatology. He condemns the use of the injection method in treatment and advocates laparotomy at the earliest possible moment after diagnosis as the best and only treatment, claiming that with judicious after-treatment there would be but a small percentage of deaths. He thinks that manipulation may usually be effective in reducing the intussusception and commends Maunsell's method of enterorrhaphy as having the great advantage of rapidity; he also recommends, when ordinary reduction is impossible, the making of quite a short incision through the 2 layers of the intussusciptens down to the intussusceptum, freeing the adhesions with a probe, and by pressure from below reducing the intussusception, when the long incision into the bowel may be closed by Lambert sutures. This should only be employed when there is nothing to point to excision, *i. e.*, when moderate adhesions only are the cause of irreducibility. After-treatment, in his opinion, should include full nourishment of the child, since many cases of death are due to starvation and consequent exhaustion. He thinks that surgeons often overlook the fact that in this condition the child has taken little food for 24 hours or more before operation. [M.B.T.]

6.—Bateman reports 3 cases in which **antistreptococcus serum** was used. The first patient was a woman of 39, who suffered from septic pneumonia, following the puerperium. Exploratory puncture of the right pleura was negative, and, although bacteriologic evidence was wanting, the serum was given in small doses, first 1 cc., then 2 cc., and finally 3 cc., daily. The patient recovered. The second patient was a woman of 27, who also had septic pneumonia following the puerperium. There was a right-sided purulent pleural effusion of 22 ounces, which was withdrawn and found to contain streptococci. The empyema was tapped twice more, and then developed a pneumothorax in addition, for which a portion of the eighth rib was resected. Antistreptococcus serum, in daily doses of 1 cc., was given after the operation, and, with the exception of a labial abscess, recovery was uncomplicated. The third patient was a woman of 26, who had vague signs of puerperal sepsis, for which she was given 10 cc. antistreptococcus serum, with some temporary benefit. Six other injections seemed to have no effect. The patient had pericarditis, was restless, and presented an erythematous rash, which desquamated. She died suddenly from heart-failure. For 6 days she received a daily dose of 1 cc. of antistreptococcus serum. There was no autopsy.

7.—Tuckey reports two cases of **agoraphobia** that were cured by hypnotic suggestion. The first patient was a young woman, aged 26, and the second was a man of 37. [J.M.S.]

8.—Fraser reports a case of retroverted uterus which had become incarcerated, the patient was about 3 months pregnant and suffering very much from distention of the bladder. After failing to pass the female catheter, a fine, flexible, male catheter was inserted and a large quantity of urine drawn off. After allowing the patient some time to rest after this relief, she was placed on knees and elbows and the first two fingers of the left hand, suitably prepared, were now gradually worked up the rectum. After 8 or 10 minutes' firm, steady upward pressure, and when he was beginning to despair of any result, complete reposition took place suddenly and the patient was completely relieved. No vesical or other trouble followed. [W.K.]

9. Notes from Fever Wards. J. G. McNAUGHTON.

1.—Harris's experience in **pulmonary tuberculosis** has been that at the beginning of definite illness the weight of the patient has begun to diminish, and that this diminution in weight has gone steadily on until the patient put himself under treatment. The two chief means that we have at our disposal for the **treatment of wasting in phthisis**, even when there is marked fever present, are (1) rest and (2) regulated feeding. The object that we should aim at is not to increase the weight of the patient by a mere disposition of fat; but rather to set up a more healthy metabolism in the tissues, and especially in the muscles, in which so much of the active metabolism takes place. It is unwise to increase any one of the 3 varieties of foodstuffs to any large extent at the expense of the others. Even at the risk of retarding the marked increase in weight, if any one of the 3 kinds of foodstuffs is to be increased, it should be the proteid. The following methods may be employed to combat anorexia: (1) Give the food in the most appetizing form possible; (2) give frequent small meals; (3) direct the patient to eat the amount of food given him, even if he has no appetite; and (4) forced feeding. Various proteid productions are to be obtained that consist almost entirely of albumoses, and when the digestion is markedly below normal recourse might well be had to some of these. [J.M.S.]

2.—The most favorable cases of **goiter for medical treatment** are undoubtedly those of simple parenchymatous enlargement of the thyroid gland, occurring in **adolescents and young adults**. In these cases, treatment by thyroid extract, so as to supply for a time the excess of secretion which is required from an external source, is of great service. Liquid extract or dry thyroid may be given. The former may be given in doses of 15 minims 2 or 3 times a day, while the latter may be given in doses of 3 or more grains, at the same intervals. Murray reports the case of a girl, aged 13 years, in whom both lobes, as well as the isthmus of the thyroid gland, were greatly enlarged. Treatment was commenced on March 21, and in 5 days the goiter had distinctly diminished in size. Between March 21 and April 12 the circumference of the neck had diminished from 16½ inches to 13¾ inches. A second case was that of a boy, aged 16, who had a considerable uniform enlargement of both lobes and the isthmus of the thyroid body. Dry thyroid in 3-grain doses, twice a day, and red iodid of mercury ointment by inunction nightly, caused steady reduction in the size of the goiter until it appeared only half as large as it had been. A third case was that of a girl, aged 13, who had a considerable uniform enlargement of the thyroid body that caused dyspnea. Similar treatment caused relief of the dyspnea, and

the circumference of the neck was reduced about 3 inches. The author is of the opinion that in all case of goiter which are to be subjected to operation, the patient should be treated by thyroid extract for 2 or 3 weeks before the operation, so as to reduce the size of the goiter, and so that the superficial veins may be reduced in size, and the operation, in consequence, be more easily performed. [J.M.S.]

3.—Jones in the fourth of a series of articles on **surgical gynecology**, speaking of the influence of conservatism upon operative technic, says there is nothing in the teaching of present-day leaders in gynecology that justifies the removal of unhealthy parts, which experience has proved may in time be restored to health and the discharge of their normal functions; and certainly nothing to warrant any mutilation of the genitalia, on the assumption of the probability that such removal may be called for in the future. Touching the question of carcinoma, he holds that malignant disease of the uterus of any type demands early and complete removal of that organ and its appendages. Conservative measures should be used only when operation is contraindicated. The presence of lacerations of the cervix is a predisposing cause to cancer. Neither should there be long delay in case of tumors of uterus or adnexa. The policy of delay works badly every way. Women continue to be invalids, many die from intercurrent attacks of peritonitis, and those who live do so with lessened chances of recovery when they submit to operation, and greatly increased risks of but partial restoration to health. [W.K.]

4.—Gibbs is of the opinion that the **presystolic murmur of mitral stenosis** is composed of 3 parts: (1) The audible right ventricular vibrations. In consequence of the lack of synchronous action of the two ventricles a portion of the systole of the right ventricle takes place and its muscular vibrations are heard while the left ventricle is in diastole. (2) A murmur caused by the flow of blood from the left auricle into the left ventricle. (3) The slapping first sound. The author's experience leads him to believe that in pure mitral stenosis the apex beat is always formed by the right ventricle and that the left ventricle is not in contact with the chest-wall. He considers that the predominant feature of mitral stenosis is the want of synchronism in the action of the 2 ventricles, the right assuming in part the function as well as the rhythm of the left auricle. [J.M.S.]

6.—Lackie reports a case of **suppression of urine** following cystitis. The patient, aged 43, enjoyed perfect health until about 9 years ago, when she began to suffer from distressingly frequent and painful micturition, followed by the passage of a few drops of blood. Examination of the urine showed the presence of pus, blood, mucus, and phosphates, but no renal casts were found. The usual general management failed to bring any relief, and as she seemed to be growing worse, the urethra was dilated and the bladder thoroughly explored. This brought relief from the distressing symptoms, but resulted in incontinence of urine. She however felt so well that she returned home, and supplying herself with a portable urinal was able to live quite comfortably. Eight years later Lackie was called to see the same patient, who had been pretty well until a fortnight before she began to suffer from nausea and vomiting, and for 8 days had passed no urine. After 2 days' treatment, the urine, which was found to contain albumin, pus, and tube-casts, but no blood, began to flow freely. She continued to improve for 8 days, when somewhat suddenly all her former symptoms returned. She had intense sickness and vomiting, complicate suppression of urine again, and she gradually lapsed into a comatose state and died 4 days later. A postmortem showed that the substance of the left kidney had been entirely replaced by tuberculous caseous material, and the ureter was greatly atrophied and absolutely occluded near the bladder, and the right had been the seat of a recent very acute catarrhal nephritis. This, then, was a case of nonobstructive suppression of urine in which the patient died without any marked symptoms of uremia whatever. This supports the modern view that the symptoms from obstructive and nonobstructive anuria may be exactly similar. [W.K.]

7.—Gibson reports a case of **ureterovaginal fistula** cured by ureterocystotomy. He has no doubt the cause of the fistula was a silk ligature used to control the hemorrhage from adhesions at the time of a former vaginal hysterectomy. Had the suture been of less persistent material the ureter would undoubtedly have resumed its function after the

absorption of the ligature. He considers ureterocystotomy preferable to any plastic operation, to either partial or total colpoceleis, or to nephrectomy; indeed, the last is not to be thought of unless the kidney is badly diseased. [W.K.]

8.—Agnes Bennett reports a case of **adolescent general paralysis** in a young man of 19. The patient walked in a heavy, slow, clumsy, and unsteady manner, with a wide base, rolling from side to side. The awkwardness was increased by a moderate degree of flat-foot. The tongue was protruded in an incoordinate manner. The speech was nasal, slow, blurred, and jerky, and there were often pauses in the effort to articulate. The speech rapidly became more unintelligible. At one moment the patient was laughing and bright; again he would behave like a spoiled child. He was incapable of any prolonged mental exertion. The father of the patient was phthisical, suffered from kidney disease, and had had a paralytic shock. At the age of 9 months the patient developed hydrocephalus. He began to walk at 12 months, but very soon discontinued, and did not again attempt it until he was 4 years old. He went to work in the coal-pits, where he worked till about 2 years ago, when he was dismissed on account of increasing incapacity for work and weak-mindedness. [J.M.S.]

9.—Out of 2,600 cases of **scarlet fever** under W. Naughton's observation in 1 year, there occurred 62 cases of **arthritis**; 45 females and 17 males. The wrists, the knees, the phalanges, and the elbows were most frequently involved in the order given. Occasionally one found a functional bruit over the heart, but in no case was endocarditis or its results present. Pyemic joints were found once in 4,000 cases. The 62 cases mentioned are believed to be septicemic and due either to the germ of scarlet fever or to cocci which have followed them, so that they are analogous to the rheumatism one finds in the course of gonorrhea. Six cases with affected joints had some form of heart-lesion. The author reported also a case of **scarlet fever and chorea**. Another patient was a male, aged 10 years, who had **malignant scarlet fever**. The patient was quite delirious, passed urine and feces in bed; and picked the clothing. He became cold, collapsed and cyanosed, but recovered. Then double otorrhea developed, followed by double cellulitis in the neck. The patient eventually made a good recovery. The author also reports a case of **scarlet fever and psoriasis**, and one of **scarlet fever and meningitis** in a female child aged 3 years. [J.M.S.]

9. Some Remarks Upon the Work of Dr. Deckart. RUDOLF BIERMER.

1.—Various theories have been advanced to explain the peculiar **furrows** frequently seen on the upper surface of the liver. Walz reviews them critically and comes to the conclusion that the bending of the liver occurring normally during respiration has a good deal to do with their production. In physiologic conditions, the flattening of the diaphragm in inspiration brings about a bending of the liver in such a way that the lateral portions are forced upward by the air-pressure, while the middle portion is forced downward. This causes a compression of the upper and a stretching of the lower half. The bending is most marked in the

sagittal direction along the weakest part of the liver, i. e., the line of the fissures. During expiration the opposite conditions are produced. All conditions which induce a flattening of the dome of the diaphragm or of isolated parts of the latter are capable of producing flattening, and eventually a furrowing of the liver. In typical cases these furrows run in the sagittal direction, corresponding to the direction of the furrows on the lower surface. The sagittal furrows are, therefore, a consequence of an abnormally increased bending of the liver. They cannot be called either inspiration or expiration or diaphragmatic furrows, as has been done, but only flexion furrows. [D.R.]

3.—Pregnancy occurring during lactation can bring about a marked reduction in the quantity of milk with eventual cessation of flow. Particularly healthy women may, however, be capable of nursing their children during pregnancy. As a rule, it is well to wait until there are indications that the child is not thriving before taking it from the breast. [D.R.]

4.—The following are the theses enunciated by Blum: 1. Poisons constantly arise in the organism which under normal conditions are neutralized by the thyroid gland. 2. These poisons originate in the intestinal tract (enterotoxins), most probably as the result of decomposition of albumins. 3. If the activity of the thyroid gland is suspended and the enterotoxins are enabled to act, they produce grave disturbances associated with demonstrable anatomic changes. In acute cases only the central nervous system is altered; in more chronic cases the kidneys suffer. 4. Those animals which either spontaneously or after treatment remain healthy after extirpation of the thyroid gland, or recover from its effects, possess in their blood protective substances against the enterotoxins. 5. In the transit through the thyroid gland the enterotoxins are deposited as highly molecular compounds (thyrotoxalbumins) and are gradually rendered harmless. The iodine-substance of the gland formerly considered as specific, is only an intermediate specific in the transformation process. 6. To this thyrotoxalbumin, which in normal conditions of the gland never enters the circulation, there exists a natural, as well as an acquired immunity. 7. Immunity to the enterotoxins does not involve immunity to the thyrotoxalbumins, and vice versa. 8. Animal experiments render it highly probable that even in man several diseases occur which are connected with intestinal changes and insufficiency of the thyroid gland. The experiments also modify the existing concepts regarding the nature of certain diseases of the thyroid, particularly myxedema and Graves' disease. 9. Therapeutic measures also follow from the experiments. [D.R.]

5.—Rumpf complains that too many cases of advanced tuberculosis are sent into the sanatoria, and considers the erection of stations for observation of cases a necessity. [D.R.]

6.—A description of a portable case containing the necessary utensils for making an examination of the stomach and its contents. [D.R.]

8.—Krönig and Blumberg sum up the results of their researches over the value of the different methods of **hand-disinfection** as follows: 1. The purely mechanical method of disinfecting the hands with just water, soft soap, and brush gives very unsatisfactory results. 2. Ahlfeld's hot water and alcohol method of disinfection will not cleanse hands which have been infected so that all danger of carrying germs to the wound is removed. This method consists in washing the hands for 5 minutes with soap and water, then for 5 minutes more with 96% alcohol. 3. A much better result is obtained when the mechanical method is combined with a solution of one of the salts of mercury. 4. A 3% solution of citrate of mercury and ethylenediamin (10% solution is made as follows: ethylenediamin 4 parts, citrate of mercury 10 parts, and water 86 parts) is much better as a disinfectant for the hands than a 1% sublimate solution. The former does not irritate the surface of the skin, does not form other salts with albumin or the blood, and possesses a more intense and more penetrating bactericidal action. [G.B.W.]

9. The Seventieth Birthday of August v. Rothmund. O. EVERBUSCH.

1.—A clinical description of the **plague at Oporto** in 1899. Regarding the treatment the author does not feel that the small number of cases subjected to the serum-therapy permits a conclusion. [D.R.]

2.—Strohmayer has not seen the vaunted effects of Credé's silver ointment in septic diseases. [D.R.]

3.—Behm reports a case of **congenital cerebral hernia** situated between the smaller fontanel and the occipital protuberance. The tumor was about the size of an egg and was attached by a broad base; it did not increase when the child cried nor decrease in size when pressure was exerted. As continued pressure did not tend to reduce the size of the growth, an operation was determined upon. The tumor was ligated in three portions and removed. There was considerable parenchymatous bleeding, but this was easily controlled by suturing together the overlying structures. There were no unusual symptoms following the operation, and the wound healed readily. The subsequent history of the case was most satisfactory except that at the seat of the operation, a small fluctuating projection developed. Examination of the specimen showed it to be what Bergmann terms an **encephalocystocele**. A quantity of fibrous tissue separated the tumor from the brain proper. [G.B.W.]

4.—Glauning reports 3 cases of **infected wounds of the eyeball** showing the excellent results which may sometimes be obtained by a paracentesis of the anterior chamber, made with the galvanocautery. This small operation is carried out as follows: After proper instillation of cocaine, a fine platinum electrode heated to a red heat is carried slowly through the various layers of the cornea until the fluid of the anterior chamber flows out through the minute opening. In case a hypopyon exists the pus will readily be expelled. The conjunctiva is then washed out with warm normal salt-solution and both eyes bandaged. Pain developing subsequent to the operation may be controlled by cold applications. If the single puncture does not suffice and the inflammatory symptoms reappear, the procedure should be repeated, but not before 4 or 5 days have elapsed. [G.B.W.]

5.—In this apparently unique case of **rupture of the eyeball** from spontaneous internal hemorrhage, no cause for the bleeding could be discovered, though the patient had suffered from previous attacks of nosebleed. The tear began 1 mm. from the upper border of the cornea, running concentrically for 6 mm., then bending at a right angle went backwards for 4 mm. [G.B.W.]

6.—Paul and Sarwey, as the results of their experiments over hand-disinfection, give the following conclusions: 1. It is not possible to make the hands free from germs by either of the following methods; washing with soft soap, brush and hot water, or washing in running sterile water with either Schleich's marble soap or Sanger's sand soap. 2. It is not possible by any purely mechanical means to remove all the germs from the hands. 3. It is not possible to reach the same amount of disinfection of the hands with mechanical means as it is with chemical, and to obtain the nearest approach to sterility the chemical applications should always follow the mechanical washings. 4. Soft-soap because it contains free alkali should not be used for washing the hands. 5. Schleich's marble soap is very good for cleansing the hands from ordinary dirt, but as it does not thoroughly remove the wax is not so appropriate as a forerunner for the disinfectants. 6. Sanger's sand soap, because it contains ammonia and soda, is an excellent preparation for getting the hands ready for the action of the various disinfecting chemicals. [G.B.W.]

7.—The authors show that the organism producing gaseous phlegmons in human beings belongs to the great group of

butyric acid bacilli. Of these bacilli there are 2 kinds—a motile and a nonmotile. The gas-phlegmon bacillus belongs to the nonmotile variety. [D.R.]

Centralblatt für Gynäkologie.

February, 24, 1900. [24. Jahrg., No. 8.]

1. Remarks on Pressure Therapy for Retroflexion of the Gravid Uterus. A. FUNKE.
2. Upon Laceration of Vaginal Tissues Upon Coitus and Other Rare Cohabitation Injuries. O. SCHAEFFER.
3. Lying-in-Hospitals and Reform of the Hygiene of Delivery and the Puerperium. MAX SPERLING.

1.—Funke considers that the importance and excellence of the **pressure therapy** has been shown in publications by Halbahn, Freund, and himself. The use of the shot-pouch belongs to daily practice in chronic affections of the genitalia and in uterine displacements, being especially adapted to retroflexion of the gravid uterus. He has found pressure therapy very efficacious in 4 such cases, one of which he reports in detail. The bimanual examination of the patient, a woman aged 34, led to a diagnosis of retroflexion of the gravid uterus, the portio vaginalis being above the symphysis and the uterus lying in the pelvis. Into a colpeurynter placed in the vagina, 1,000 grains of quicksilver were introduced and almost immediately withdrawn, when the uterus was found already raised above the symphysis and a much smaller part of it in the small pelvis. The quicksilver colpeurynter was again applied and allowed to remain half an hour, when an examination showed the uterus in an erect position with the fundus 4 to 5 fingers' breadth above the symphysis, a prompt result reached by trifling means. The advantages of this method are its certainty, harmlessness, and freedom from the use of any anesthetic. In using either the shot pouch or the quicksilver colpeurynter for retroflexio uteri gravidi, the application should not continue more than $\frac{1}{2}$ to 1 hour at most. One advantage of the shot pouch is that the direction of the pressure can be changed and corrected, and another is its plastic adaptability to the mechanical conditions of the pelvis (best secured by fine shot), while the quicksilver maintains the roundness of the pouch. This treatment is of value in a large contingent of cases of adnexa tumors, and inflammatory adnexa. The advantage of the quicksilver colpeurynter is that it is tractable and comfortable and is especially adapted to the use of the busy physician who cannot make long or frequent visits, since the patient can herself remove it while she cannot remove the shotpouch. As the introduction of the colpeurynter is often very painful, to obviate this difficulty Funke has contrived an apparatus with 2 pouches of different sizes connected by a glass tube about 30 cm. in length, the larger rubber sac contains the quicksilver while the smaller one by compression can be emptied of air. In this empty condition it is introduced into the vagina, then the other being held above by a slight pressure its contents pass into the smaller one. After the lapse of sufficient time the patient is raised up on a cushion, the larger pouch put in a lower position, and thus the quicksilver with a slight pressure is withdrawn. [W.K.]

3.—Sperling refers to the establishment of **lying-in hospitals** in different states throughout Germany during the last 20 years, and their value as places for the instruction and training of midwives in the a sepsis and antisepsis of obstetrics. As the midwives are the chief obstetricians for the masses of Germany, this training is very essential in order that the benefits of modern methods may reach all classes. [W.K.]

1. Cesarean Section on the Dying. Living Child. A. PARKES.
2. Further Remarks on the Use of Reindeer Sinew as Suture and Ligature Material. W. F. SNEGUIREFF.
3. Complications of Myoma and Pregnancy. F. WALZER.
4. Once More upon Narcosis. KOBLAUCK.

1.—It being known that **postmortem cesarean section** results unfavorably, experience having proved that fetal life becomes extinct through asphyxiation before the death of the mother, physicians began to consider the wisdom of

not awaiting the death of the mother, but to operate at once, hoping to save the child's life. Roser was the first to perform this operation successfully, Fischer, Fehling, and others following him. Parkess reports a case in which, in the interest of the child, he performed cesarean section on a woman aged 25, who, 8 hours after the operation, died of edema of the lungs. The child, a boy, 45 cm. in length, lived and grew vigorously. [W.K.]

2.—Sneguireff recommends **reindeer sinew** very highly as **suture and ligature material** because of its firmness, its capacity of being absorbed, and also being perfectly sterilized. For these reasons he thinks it especially adapted to surgery in abdominal and all other cavities. A valuable peculiarity of this sinew for ligature is its primary and secondary firmness, the knots do not loosen in the course of the operation nor afterwards, hence a secondary hemorrhage need not be apprehended, at least none had occurred in his experience. Sneguireff concludes with the remark, based on 20 years' experience in abdominal and pelvic surgery, that antiseptics and asepsis had had as a result the most extraordinary progress in abdominal surgery; but the ideal of aseptic principles had been reached in the last years of the nineteenth century in the introduction of sinew thread as suture and ligature material. [W.K.]

3.—Walzer believes that a **myoma complicating pregnancy** indicates an artificial abortion, when the conditions existing render delivery by the natural way impossible, without great danger to both mother and child, and when the mother has abandoned the hope of a living child, and only her own welfare is to be considered. He reports a case in which the mother refused to permit interference with pregnancy, although suffering extremely, but spontaneous abortion occurred, from which she recovered sufficiently to leave the hospital, returning after 4 weeks, when supravaginal amputation was performed. This case is an illustration of Hofmeier's assertion that a myoma gives no ground for sterility. Another point worthy of mention is the symptomless retention of the entire placenta in a myomatous uterus for 4 weeks, during which the woman worked, and took care of her sick father. [W.K.]

Centralblatt für innere Medicin.

1. On the Position Assumed by Acute Pericardial Exudates. F. APARTI and P. FIGAROLI.

1.—The authors have repeated the experiments of Damsch (previously abstracted from *Zeitschrift f. klin. Med.*), excepting that instead of removing portions of the ribs they introduced a canula directly into the pericardium and injected agar solutions through this. Their conclusions are that **pericardial effusions** can be determined to be present by percussion only when they have reached 150 to 200 cc. in amount. The maximum amount "which can collect" in the pericardium is 600 to 700 cc. In the horizontal position the cardiac dulness is widened in all directions proportionately to the amount of the effusion. In the vertical position the increase is chiefly in the region of the apex beat and in the heart-liver angle. In the horizontal position even small exudates surround the great vessels to some extent. In the vertical position the base remains free even with large exudates. [Certainly the statement as to the amount that can collect in the pericardium is an error—either in wording or in fact—700 cc. may be the largest amount that can be forced into a normal pericardium in a dead subject, but that it is not the largest amount that may collect in disease is sufficiently clear to the reviewer, since he has removed as much as 2,300 cc. from the pericardium at necropsy. D.L.E.]

August 25, 1900.

1. Remarks Upon Percussion of Acute Effusions Into the Pericardium. SCHÜLE.

1.—Schüle refers to his work on this subject (*Münch. med. Woch.*, 1898, No. 51), in which he reached the same conclusions as Aparti and Figaroli (*Centralbl.*, No. 29, 1900). He also found 700 cc. to be the minimum amount that he could inject, but thinks that the conditions are different in disease, and that in order to be conclusive the experiments should be conducted on the cadavers of those who have had an acute hydropericardium. [D.L.E.]

September 8, 1900.

1. A New Volumetric Method for the Quantitative Estimation of the Purin Bases in the Urine. ADOLF JOLLES.

1.—The urine is boiled with a little dilute acetic acid if it contains albumin and then filtered. If free from albumin this is omitted. The phosphates are precipitated out with magnesia mixture, then ammoniated silver solution added as in the Ludwig-Salkowski uric-acid method, the precipitate washed into 80 or 100 ccm. of water, magnesia added and the mixture heated until the ammonia is driven off, and then the nitrogen of the alloxin bodies estimated directly in the silver precipitate. After breaking up with a sulphate of an alkali, 20 to 30 cc. of sulphuric acid is added, the mixture warmed, potassium permanganate added until the color remains. After 15 minutes boiling, the fluid is cooled, made slightly alkaline with NaOH, and the nitrogen estimated with bromin, according to the author's method. Jolles claims that after oxidation in the above manner practically all of the nitrogen of the **purin bodies** is liberated, and presents tables comparing his method with those of Camene and Haycroft, and uric-acid estimations made in a similar volumetric way are compared with results by the Ludwig-Salkowski method. He considers that his method is more nearly free of error than any other (a statement that must as yet, considering the dispute into which the bromin method has justly fallen, be taken *cum grano salis*). [D.L.E.]

41. Smaller Communications.

26.—Rammstedt says that experience shows that when the **neck of the femur is injured** during the age of puberty the position of the lesion as a rule is situated at the epiphyseal line. This has been demonstrated by cases reported by Hoffa, Kocher, Sprengel, and v. Bramann. These separations of the epiphysis show more or less marked variations. They vary from a total separation to a partial downward displacement of the fragment, or possibly only a loosening of the femur head. The less the degree of actual separation the more closely does this injury resemble the true coxa vara of adolescence, for in those cases in which there is great displacement of the fragment, such deformities as result from contractures appear, also marked functional disturbances, ankylosis and possibly arthritis deformans are apt to appear. He reports 8 cases from his own experience. [G.B.W.]

27.—Israel says that among the absolute indications for

operative relief in cases of **renal calculi**, the following stand as most important: Anuria, acute pyelonephritic infection, severe hematuria, and the supposed presence of a malignant tumor. In all of these the condition present threatens life so that operation is positively demanded, but in the large majority of cases which come under the care of the surgeon there is no immediate danger so far as life is concerned, and then the question of operation is more difficult to decide. Israel says that the danger which accompanies nephrolithotomy is so slight when compared with the ultimate result of leaving the stone in place that it practically counts for little so far as indications for operations are concerned, so that even in cases where the presence of the stone is not absolutely proved, but where there is a distinct history of renal colic, one should proceed to operate rather than wait for a stone to be passed spontaneously. If a stone can be felt in the ureter through the rectum or vagina operation is, of course, indicated. As to the operation itself nephrolithotomy is much to be preferred to pyelolithotomy, the former allowing more room for searching for the stone, and the kidney is much more easily sutured than is the pelvis of that organ. Also in cases where a pyelonephritis exists in conjunction with the stone, incision through the parenchyma possesses obvious advantages over incision through the wall of the pelvis. Nephrolithotomy should be done as early as possible in order to avoid operating when the patient is already suffering from beginning uremia. [G.B.W.]

28.—Nicoladoni has successfully **transplanted the second toe** of the right foot on to the stump of the right thumb. The method was as follows: A large 2-cornered flap was raised from the region over the back of the second metatarsophalangeal joint, the extensor tendons cut and the joint opened. The end of the first phalangeal bone was then removed and the flexor tendons divided. The toe was then approximated to the stump of the thumb, which had already been prepared, and the flexor tendons of the toe united with the flexor tendons of the thumb and extensor tendons with extensor tendons. The bone was held in place by catgut sutures and the dorsal skin-flap of the toe stitched to the skin on the dorsum of the thumb. The parts were held in place by a plaster-of-paris bandage until circulation between the toe and hand had been established, and then the toe was freed from the foot by a v-shaped incision through the plantar tissues. [G.B.W.]

29.—In considering the etiology of **retropharyngeal abscess**, a knowledge of the topography of the lymphatic glands and vessels of this part of the neck is most important. In children there exist 2 sets of glands, a small chain situated near the middle line, which is not constant in either its existence or position, and a second and more important group which, being placed more laterally, is called the glandulae pharyngeales laterales. These lateral glands may persist into late adult life, but the smaller and more central chain atrophies and disappears as the child grows older. The lymphatic vessels which run to these glands arise from the posterior wall of the oropharynx and nasopharynx, from the interior of the nose and the accessory sinuses, and possibly also from the internal ear. The faucial tonsils are not in direct communication with these glands. [G.B.W.]

30.—The method of **gastroenterostomy**, proposed by Credé, is briefly as follows: Three oblong and flat plates are used, each containing 2 small holes for the passage of the fastening threads. The posterior wall of the stomach is reached through an opening made in the mesocolon. A high loop of the intestine is selected and opened for from 1 to 1½ cm. Two of the plates are threaded together with a bit of rubber tubing between them, and inserted into the intestine. A small, olive-shaped piece of silver is fastened to the innermost plate by a strand of thick catgut, and placed in the efferent limb of the gut; this silver facilitates the passing of the plates in the proper direction, after necrosis of the intestinal wall has set them free in the lumen of the gut. The intestinal wound is sutured, the ends of the thread sticking out. An opening is then made in the anterior wall of the stomach, through which the remaining plate is inserted. The threads from the intestinal plates are passed through the posterior wall of the stomach by means of needles, and carried through the holes in the plate in the stomach. The threads are firmly knotted, and the incision in the gastric wall closed. The rubber-tube between the 2 intestinal plates keeps up

a steady pressure until in the course of a few days the intervening walls necrose and the opening between stomach and intestine is established. The plates are readily passed in the course of 10 to 20 days. Another form of these plates have large central fenestra, which afford immediate communication between the approximated viscera. Enterostomosis is done in a similar manner, the 2 plates being placed in the efferent limb. [G.B.W.]

31.—As an improvement in the technic of **joint-operations** König suggests that in cases which are aseptic at the time of operation, the manipulations as far as possible should be carried out with instruments so that the finger or hand does not come in contact with the inside of the joint. Also in those joints which are still free from the invasion of microorganisms, asepsis should be practised rather than antiseptics and all irritating disinfectants should be rigorously avoided. In joints already invaded by bacteria, the old-time method of draining with tubes should be discarded and free incisions with wide opening of the joint should be done so soon as the presence of pus is detected. Especially in the gonorrheal joint-inflammations will an early and free opening of the joint not only afford relief from pain, but will hasten and improve the ultimate result. [G.B.W.]

33.—If there is a decrease in the quantity of urea secreted, so that the daily amount falls below one-half, *i. e.*, about 16 grams, it should be taken as pretty good evidence that there exists an insufficient **functional activity of the kidneys**, and the removal of one of the kidneys should not be undertaken. Regarding the determination of the activity of the kidneys the following data is of much interest. When the kidneys are normally active the freezing point of the blood is 0.56° C. If the freezing-point rises so that it reaches 0.58° to 0.60° a disturbance in the functional activity of the kidneys is indicated, and one should refrain from operating until the freezing-point has returned to its normal, 0.56°. If the freezing-point of the urine falls below 0.9°, an insufficiency of the kidneys is likewise indicated. A still more positive indication regarding the functional activity of the individual organ is afforded by the examination of urine which has been obtained by catheterizing the ureter. The urine thus obtained should be examined as to the amount of urea present but by far the most satisfactory results will be secured by the estimation of its freezing point. [G.B.W.]

34.—Sudzuki, in speaking of the **diverticulums of the sigmoid flexure**, says that there are 3 causes for the formation of the so-called false diverticulums: 1. Lessened resistance at the exits of the bloodvessels due to the loose connective tissue and the presence of fat. 2. Pressure exerted by the feces and gas. 3. Muscular action. For the development of the true diverticulums the pressure of the feces and gas holds, as in the cases of the false, a very important place. The muscular action also helps greatly in their formation. [G.B.W.]

35.—In this case of **chondromatosis of the capsule of the knee-joint**, the condition had been gradually developing for 5 years. At the operation the whole capsule, which was considerably larger than normal, was found to contain numbers of cartilaginous plates, some the size of the palm of a woman's hand and as thick as a finger; there were numbers of smaller nodes covering the internal surface of the capsule and many free bodies were present in the joint. An arthrectomy was performed and the wound packed for 4 days with iodoform gauze. At the end of this time the packing was removed, the resected surfaces fastened together by a couple of sutures and the skin-wound closed. The patient made a good recovery and was able to return to his work with a useful but stiff limb. [O.B.W.]

36.—Hoffa reports 4 cases of **torticollis** on whom he operated after the manner of Mikulicz, by resecting the sternomastoid muscle from its sternal attachment to the exit of the spinal accessory nerve. The result was most satisfactory in all the cases, the patients being able to hold the head erect not only without tiring but without effort; the head could be moved easily towards either side, and the spinal column once more assumed its normal posture. The cosmetic result was also satisfactory. [O.B.W.]

39.—Wohlgemuth, in speaking of **fracture of the greater tubercle of the humerus**, says that this injury is very uncommon when existing by itself, but as a complication to fracture of the upper end of the humerus or to dis-

location of the shoulder joint, it is much more frequent than is generally supposed. The diagnosis of this injury, when existing as a complication, is generally accompanied with the utmost difficulty, so that when an injury of the shoulder is accompanied with an unusual amount of functional disturbance resort should be had to the x-rays in order to clear up the diagnosis. The treatment of this fracture consists in strong abduction of the arm when the fragment is found to be displaced upwards, and in both outward rotation and abduction when the fragment has been drawn backward. Fastening the fragment in place by operation is not commended. [G.B.W.]

40.—König says that in order to avoid as much as possible the hemorrhage which occurs during resection of the upper maxilla, it is best to ligate the external carotid between the superior thyroid and lingual branches. One of the worst features of the extensive removal of the upper jaw, when it has been necessary to remove the floor of the orbit, is the disturbance of the position of the eye, so that double vision or atrophy of the optic nerve develop. In order to furnish a firm floor for the eye König purposes that a flap be taken from the anterior border of the temporal muscle, including a portion of its insertion on the coronoid process of the lower jaw and swung under the eye and attached to the periosteum of the stump of the frontal process of the upper jaw. The 2 cases are reported on whom this procedure had been carried out. In one the result was, in spite of marked suppuration, a success, and the eye on the diseased side was held to an equal height with the normal organ. In the other case the patient died before a final result could be noted. [G.B.W.]

23. The Bronchial Muscles and Asthma. AUFRECHT.

18.—Starck describes the clinical symptoms of a typical but probably imaginary case of **Zenker's pulsion diverticulum**, and then describes in order the various symptoms. The prodromes consist of the symptoms of irritation; that is, expectoration of mucus, the secretion of an abnormal quantity of saliva, slight symptoms of stenosis, as an uncomfortable feeling in the throat and anxiety lest the solid particles of food become impacted. The direct symptoms are those of stenosis, that is, a sense of pressure in the throat with occasional inability to swallow food; the obstruction being apparently situated about the middle of the neck. Then from time to time there may be regurgitation, sometimes followed by renewed chewing. The regurgitated material is characterized by the fact that there is no trace of digestion. The quantity varies considerably according to the size of the diverticulum. A stenosis is brought about apparently in 2 ways: either by pressure of the sac filled with food upon the esophagus and by the stretching of the esophagus at the point of the opening so that its lumen becomes a narrow slit. Finally, there may be actual contraction of the esophagus or a stenosis due to paralysis. Among the objective symptoms is the tumor in the neck, whose size and location of course depend upon the seat of the diverticulum. Curious sounds may be heard in the throat and occur usually during eating but may occur at other times; there is an extremely offensive breath which has a peculiar odor of fermentation; and sometimes the patients suffer from pain. Some indirect symptoms are disturbances in respiration, congestion of the head, both due to pressure, neuralgia, hoarseness, and finally interference with

the general nutrition. In fact, a considerable proportion of all cases die of starvation. The diagnosis of course is to be made from the symptoms. Among the aids are the esophagoscope, which does not appear to be of great value; the esophageal bougie, which under favorable conditions may be extremely useful; and finally the electric sound, which appears to pass the opening of the diverticulum much more readily than the simple bougie. The size of the diverticulum may be tested either by filling it with water and then measuring the quantity that flows out, or by filling it with a solution of bismuth and observing directly with the x-rays. Einhorn's stomach lamp may also be employed. The prognosis is gradually improving of late years, as a result of surgical interference. The treatment may be divided into the internal and the surgical. The stenosis may be treated by bougies which rarely, however, give much relief. Hollow bougies may be employed for the purpose in patients who have great difficulty in swallowing. In many cases it is only possible to pass the instrument after the tip has been bent slightly and directed forward. The patients sometimes are obliged to eat in an unusual position, that is, with the head bent to one side; to consume only liquid food, and to empty the diverticulum either by external pressure or by washing. If there are symptoms of starvation, rectal enemas should be employed. The operative treatment consists either in the direct removal of the diverticulum, its invagination into the lumen of the esophagus, or in gastrostomy for the purpose of feeding the patient. The latter appears to have been fatal in all cases. Starck describes the different operations and mentions the more important complications. [J.S.]

19.—Hensen has performed a series of experiments with the sphygmomanometer of Riva Rocci with the object of determining the normal blood-pressure and the modifications that are produced by various diseased states. The apparatus consists essentially of a flat rubber tube which is laid around the upper arm, the ends made fast, and then distended by means of an ordinary pump. Between the pump and the tube a mercurial manometer is placed so that the amount of pressure can always be readily determined. In using this instrument, it is placed in position, then distended, while the radial pulse is carefully watched. At the moment the pulse disappears the manometer is read, then the pressure is gradually released, and the moment the pulse reappears a second reading is taken. This usually represents the pressure necessary to occlude the artery, that is to say the pressure corresponds to that in the bloodvessel itself. Hensen gives an elaborate analysis of the use and advantages of the instrument, and makes a number of technical suggestions regarding its employment which cannot here be discussed. In normal persons he obtained the following results: in 25 workmen between 17 and 30 years the blood-pressure varied between 105 mm. and 158 mm.; in 30 women of the same age, between 105 mm. and 160 mm., the average being slightly less; in 25 healthy children, from 3 to 15 years of age, the limits were from 80 mm. to 135 mm., and the average 116 mm. Pressure seems to increase slightly with advancing age. In old persons the pressure increases and the upper limit reaches 170 mm. The mean varies from 140 mm. to 150 mm. Moderate variations in pressure constantly occur, in extreme cases reaching 40 mm. to 80 mm. per day. In the evening pressure is usually 5 mm. to 15 mm. more than in the morning. Other arteries in the body were tested, and it was found that the more remote they are from the heart the greater the pressure. The blood-pressure in the arteries above the diaphragm was increased from 8 mm. to 15 mm. by pressure upon the abdominal aorta. In pathologic conditions, 2 types of changes are recognized: the functional and the organic. Hensen includes in the functional all those conditions in which the activity of the heart and bloodvessels is altered, and the quantity of blood is changed, such as fever, anemia, pleural exudates, uremia, etc. The organic or essential conditions are those of which there are pathologic defects of the bloodvessels, such as arteriosclerosis, valvular heart-disease, nephritis, aneurysm, etc. Practically the only change is increase in the blood-pressure. Diminution of blood pressure occurs only in the agony with the exception of a few rare cases. A number of investigations have been made upon this point, and it was found that when the pressure reached 70 mm. death was inevitable. If it even reached 95 mm. and the general condition of the patient was bad, prognosis was unfavorable.

In cases with pathologic increase in the blood-pressure, the limit at which life can persist is much higher. Usually, just before the agony develops, the blood-pressure is normal or even slightly increased as the result of the dyspnea. Hensen then discusses certain peculiarities of the blood-pressure in meningitis, the alterations that can be observed in cases of inequality of the pulse as in myocarditis; changes that occur during respiration which are particularly pronounced in cases of pleural exudate, the variation reaching as much as 40 mm. In dyspnea probably the highest pressure occurs in cachexia, and in marasmus pressure apparently does not fall below the lower normal limit. In febrile conditions, such as typhoid, in which the pulse feels soft and relaxed, the fact that the pressure is not abnormally diminished indicates that the splanchnic vessels, which chiefly govern blood-pressure, do not take part in the relaxation. Usually in acute fevers, there is increase in the blood-pressure corresponding to the height of the fever. Sudden increase in the blood-pressure during fever is usually an indication that the case is becoming critical. After the disappearance of fever, the pressure usually diminishes. Curiously enough neither in collapse nor after profuse hemorrhages was there any marked decrease in blood-pressure. It is probable that in the latter instance there was some compensation brought about by the increased activity of the heart. In arteriosclerosis, as was to be expected, the blood-pressure is greatly increased and the same is true of the different forms of contracted kidney. In compensated mitral lesions the blood-pressure is not altered. In aortic insufficiency there is a very extraordinary alteration between the maximum and the minimum pressure which may amount to 100 mm. This is sometimes masked by arteriosclerosis. In general it may be said that diminished blood-pressure is not by any means invariably present in heart disease. In a few concluding remarks, Hensen states that the mean blood-pressure is probably the most favorable condition for the circulation of the blood. He believes that the blood-pressure is produced partly by the necessity of overcoming the resistance of the general vasomotor system, and partly by the necessity of meeting the various resistance of the small arteries and capillaries whose caliber is constantly changing. The former probably amounts to from 55 mm. to 70 mm., and the latter constitutes the remainder of the blood-pressure. As a result, the blood-pressure cannot be regarded as a measure for the activity of the heart, but is dependent upon a variety of conditions. [J.S.]

20.—Strasburger continues his article upon the **fermentation of feces** and gives the records of a number of experiments. He believes that an enormous liberation of gas in the form of early fermentation indicates the existence of a large quantity of carbohydrates in an easily fermentable form. When fermentation does not occur under these conditions, there is probably some deficiency in the diastase; therefore, no quantitative conclusions can be drawn in the presence of a negative result. He recognized the various types of fermentation as follows: Fermentation with much gas and the formation of acid; fermentation with gas without the formation of acid (this occurs particularly in the alcoholic stools); putrefaction with the formation of an alkaline reaction, probably due to an excess of albumin; possibly the presence of abnormal bacteria. The first form probably indicates disturbance of motility and secretion; the second, the deficient absorption of fat; the third, the deficient absorption or excessive excretion of albumin. Regarding the chemistry of the feces, he concludes that the quality of the nourishment has no influence on the quantity of amylose contained in them. The diastase is increased. In constipation it is decreased. In fever amylose is diminished. Among the other interesting results may be mentioned the remarkable action of itrol, which, in a dilution of 1 to 190,000, completely checks the amylolytic action, and inhibits it when the dilution is 1 to nearly 4,000,000. [J.S.]

21.—Thiersch has made a series of experiments in order to determine the amount of **pressure that the corset, as ordinarily worn, exerts upon the thorax**. He first estimated the amount of pressure caused by the respiratory movements at the waist, above the lower border of the ribs, and over the breast by placing a firm strap about these, to which a dynamometer was attached. He instructed the patient to take deep and shallow breaths. With an initial pressure of 1,700 grams, he found that shallow breathing

gave rise to a pressure of 2,400 and deep breathing to a pressure of 3,500 grams. When the strap was placed around the thorax the figures increased enormously, reaching 6,100 grams per deep inspiration at the upper level. The second series of experiments was made with 6 varieties of corsets that he obtained from a dealer. These were suspended vertically and the amount of distention produced by various weights carefully measured. There was considerable difference, some extending readily to light weights, but soon reaching the maximum; others only extending after considerable weights had been employed, and still others being relatively stiff. It was found further that the flexibility of the corset corresponded inversely with the amount of pressure exerted. By insertion of a dynamometer between the corset and the body of the subject, it was found that with a moderate tension, 300 grams, a pressure of 700 grams during deep inspiration could be obtained. Thiersch believes that the pressure of the skirts at the waist is far more serious than even the pressure of the corset, but he admits that women have accustomed themselves to the pressure of both, and can even lead a fairly active existence, although constantly subjected to a pressure of 1.5 to 2 kilograms around the waist. Nevertheless, permanent injury is frequently produced upon the thorax and abdomen, and therefore reform in costume is urgently required. [J.S.]

22.—Tarchetti reports the case of a man of 69, who was brought to the hospital in a state of profound cachexia, icteroid, with distention of the abdomen. As a positive diagnosis was not otherwise possible, Mariani excised one of the swollen supraclavicular glands, which contained nests of epithelial cells. As a result, a diagnosis of **cancer of the liver and pancreas** was made. In order to determine how frequently the supraclavicular glands are involved in carcinoma of the abdominal organs, Tarchetti has collected 38 cases from the records of the clinic. In 7 of these the supraclavicular glands were enlarged. In 16, none of the glands were enlarged. Two cases were not carefully recorded. He does not believe, as do most authors, that the involvement of these glands is chiefly an indication of carcinoma of the stomach, but it may occur in carcinoma of the duodenum, of the liver, and perhaps of other abdominal organs. The symptom appears to occur somewhat late in the course of disease. In 6 cases noted by Tarchetti, it appeared from 19 to 75 days before death. He calls attention to the fact that frequently the inguinal glands are enlarged in cases of carcinoma, without containing any trace of metastasis. He concludes, as a result of these facts, that the presence of swelling of the left supraclavicular glands is sufficiently frequent in abdominal carcinoma to be of symptomatic value. It is not restricted to carcinoma of the stomach, may occur at varying periods before death, presents a characteristic clinical appearance that often renders histologic examination unnecessary, whereas moderate swelling of the cervical and inguinal glands may occur without carcinoma. [J.S.]

23.—Aufrecht, having observed that even in the finer **bronchioles** of the lower animals there exists a powerful layer of **circular fibers** and a weak layer of **longitudinal fibers**, was able to demonstrate the same condition in the bronchioles of human beings, particularly in portions of the lung adjacent to the inflammatory foci. He believes that this observation enables him to supply a more satisfactory explanation of asthma than has hitherto been given. As the 2 sets of muscle fibers have an opposed action in cases of inflammatory infiltration, such as may occur in emphysema, the weaker longitudinal fibers are more affected than the horizontal fibers are, and therefore unable to oppose their contraction, and, as a result, the muscle-cramp occurs. [J.S.]

1.—Pick calls attention to the growing tendency among myologists to approximate the types of **progressive muscular atrophy**, and to ascribe them all to some disturbance of nervous influence. He believes that we should observe with particular care the following points in the study of cases: (1) The various symptoms, with the special object of determining transitional forms between the primary myopathic types and the myelopathic and neuropathic types; (2) the careful investigation of the nervous system, particularly the cells of the anterior cornua by Nissl's method; (3) when changes in the central nervous system are discovered, an effort to determine whether they are primary or secondary; (4) careful investigation of the motor nerve terminals in the muscles. He reports the case of a man 52, previously healthy, who, 2 years before admission, had developed pains in the knees. There was atrophy of some of the muscles of the neck, arms, and legs. There were no fibrillary contractions and the electric reactions were normal. He finally died as a result of abscess. Examination of the tissues showed normal spinal cord and normal peripheral nerves with the exception of slight changes in the axillary and spinal accessory nerves. The atrophic muscles showed fatty degeneration with formation of vacuoles. The neuromuscular spindles were normal. Pick gives an interesting discussion of many of the features of this case. Some of the muscle-fibers were so greatly increased in size that they cannot be regarded as due to compensatory hypertrophy. In some of the muscles which were only slightly affected, fat drops could be detected by Marchi's stain. In others the fat was very prominent. The fact that the muscle fibers in the muscular spindles were intact indicates that they have a different function from the other muscles. Pick is inclined to regard the whole spindle as a sensory organ. The slight changes in the nerves he regards as secondary to the alterations in the muscles, and the case, therefore, is to be included among the primary muscular atrophies. It is interesting on account of the age of the patient in which it developed, although he was of the juvenile type. He reports 4 other cases in which portions of the muscle were obtained by harpooning. Specimens obtained from some of these revealed some interesting pathologic changes that cannot here be described. In general the characteristics were so similar to those of the first case that all were regarded as primary dystrophies. Pick is of opinion that the general belief regarding the extraordinary trophic influence of the nervous system over the muscles does not represent a true condition, and he believes that the muscles are more independent than we suppose, and that his cases directly favor the old opinion of complete separation of the myopathic and myelopathic and neuropathic types. [J.S.]

2.—Hauck has investigated the transverse diameter of various muscles, most of them being removed during rigor mortis. In a new-born child it was found that they were practically all of the same size. As life progressed, the size of the muscle-fibers varied very greatly in different muscles, thus in the gemellus, it was at birth 7.1μ ; at the age of 2½ years 18μ , and in adult life, 61.3μ . In other muscles similar changes could be observed. The size of the muscle-fibers also depends to a certain extent upon the condition of the nutrition of the individual. In a very muscular man, the average in one particular muscle was 70.2μ , while in an old man of 78, senile and marasmic, the fibers of the same muscle were 29.7μ . The period after death also seemed to have considerable influence. Several cases were tested and it was found that the fibers before rigor mortis were larger than during rigor mortis, and that after it was diminished they gradually increased in size again. Moreover, the hardening fluid seemed to have considerable influence, causing a variation of from 33.6μ to 71.6μ , in the average diameter of

the fibers in the same muscle. In fragments taken from different portions of the same muscle, the average diameter of the fibers was practically the same. Seven dogs were also used for experimental purposes. In one the right gastrocnemius was excised, in the second the sciatic nerve cut, in the third the right leg fastened in a plaster bandage, the fourth was placed in a small cage, the fifth suffered hemisection through the dorsal spinal cord, the sixth animal was encouraged to live an active life, and in the seventh the knee and ankle-joints were destroyed by injections. In the first animal the muscle-fibers of the gastrocnemius were found to average 6.7μ , in the second comparison of the 2 sides showed a considerable diminution in the average size of the fibers in the affected muscles. In the seventh dog in which experimental ankylosis was produced there was again some atrophy in the fibers of the muscle. In the animal that had been kept in a cage it was noticed that the transverse striations were more pronounced than the longitudinal. [J.S.]

3.—Giese reports an interesting condition that occurred in 2 children of the same family, a brother and a sister. There was apparently no tendency to neuropathic heredity and the other 4 children still living are perfectly healthy. In the boy the first symptoms occurred at the age of 15, and consisted of a tremor of the hands and some impairment in the development of intelligence. Later the speech became somewhat drawling and indistinct. There was some uncertainty in the gait and the patient complained of rigidity in the limbs. At the age of 25 he was a vigorous, well-developed man, apparently perfectly healthy, without stigmata of degeneration. His intelligence was greatly impaired. Memory was feeble. There was some melancholia. There was distinct tremor of the hands and in the muscles of the face. All the reflexes were considerably increased. A sister developed some similar symptoms at the age of 16. These were practically the same, the reflexes were greatly increased, there was slight pes equinus, and also considerable resistance to passive movement. Giese then analyzes the literature of this subject and reaches the conclusion that although somewhat similar cases have been previously reported, there are none that present a similar symptom-group. He regards this disease as belonging to the **congenital** and probably the **hereditary affections**, although he admits that the etiology is exceedingly obscure. [J.S.]

4.—Krafft-Ebing reports 3 cases from the same family occurring among 7 children. Two of the children died very early; 2 are living and healthy, one of whom is only 18 months of age; and the others—the second, fifth and sixth—present the symptoms of the disease. The first case exhibited clumsiness of the legs in the fifth month, did not walk until 2 years of age, and then badly. There was evidently retarded mental development, there was exaggeration of the patellar reflex, and marked spasticity of the limbs. The electric reactions were normal. The second case, 8 years of age, exhibited the first symptoms at the end of the second year, after convalescence from diphtheria. Speech was somewhat slow. There was spasticity in the muscles and the reflexes were exaggerated. The third case, 4 years of age, first walked at the age of 2, and exhibited a peculiar alteration of gait. There was spasticity of the muscles, contractures in some, and exaggeration of the patellar reflexes. These 3 cases all present, in addition to the typical symptoms of **spastic spinal paralysis**, slight diminution of intelligence, strabismus, and disturbances of speech. In 2 cases the speech was drawling and the pronunciation was bad. Krafft-Ebing believes that there is a slowly **progressive degeneration** in the spinal portions of the pyramidal tracts, and possibly involvement of the supraspinal portions of the neurons. He excludes the possibility of chronic hydrocephalus. He reports a number of interesting cases of various conditions whose symptoms somewhat resembled those here presented, but differed in some essential particulars, particularly a case of chronic hydrocephalus with spastic spinal paralysis, and the cases of 3 children in a family of 10, all of whom had spastic rigidity of the limbs. In conclusion, he reports an interesting series of cases occurring in 2 generations and presenting the symptoms of spastic spinal paralysis. In the 3 preceding generations there had been consanguinity between the parents. [J.S.]

5.—Nawratzki reports the case of a man, 80 years of age, who presented symptoms of insanity and an **area of anesthesia** to touch and temperature on both thighs. The

patient died, and the external cutaneous femoral nerves were removed. Both were swollen to a distance of about 2 cm., both showed considerable loss of nerve-fibers, particularly at the point where they passed out of the abdominal cavity, and both contained numerous budlike structures, either homogeneous or irregularly laminated, which lay between the nerve-fibers. There were no changes in the lumbar cord. The author calls attention to the various papers which have been written upon neuralgia paresthetica, and concludes with a very interesting series of observations upon the anomalies in position of this nerve as it passes the anterior superior spine of the ilium. He found that in 11 men the distance of the nerve from the spine varied from 0 to 52 mm., and in 10 women from 0 to 58 mm. These alterations in position may account for the development of the symptoms only in certain cases and for the fact that they are often unilateral. [J.S.]

6.—Flateau reports a number of cases in which von Gräfe's symptom was present, although they were not suffering from exophthalmic goiter. This included paralyses of the arm, neurasthenia, alcoholic neuritis, bulbar paralysis, cerebral tumor, apoplexy, Thomsen's disease, etc. He gives a long discussion of the literature and of the nature of the symptom, which goes to show that this symptom occurs in a great variety of conditions. He therefore concludes that it is not of essential diagnostic significance. [J.S.]

7.—Hofmann reports an exceedingly interesting case. A man at the age of 21 suddenly fell unconscious without any premonitory symptoms. When he arose the left extremities were weak and the following day severe pains developed in them. Four years later after severe work, these pains became so severe that he fell to the ground and thereafter the weakness in the left extremities was increased. When brought to the hospital, it was found that there was total anesthesia of the left side and diminution in the functional activity of the eye and ear, loss of smell, loss of taste on that side, paresis or atrophy of the left extremities. The fields of vision were carefully taken and showed on the left side a universal concentric narrowing. On the right side they were practically normal. The muscles of the eye functioned normally, there was slight difference in the temperature of the 2 sides, the right being somewhat higher. Later the field of vision became practically normal on both eyes. The symptoms corresponded to those that Charcot asserted could be produced by the destruction of the carrefour sensation. Hofmann gives a long criticism of the literature on this subject and believes that his own case, the changes in the visual fields showed that disturbance of vision is really due to diminished volition and not to hysteria nor to simulation. It is of course impossible that destruction of the posterior portion of the posterior limb of the internal capsule should alter the functions of smell or taste, and it therefore seems likely that these as well as the disturbance of hearing are due to the same cause. He therefore believes that the symptoms described by Charcot as associated with cerebral hemianesthesia are really due to **impaired volition**, and not to destructive lesions. [J.S.]

8.—Probst, as, in a way, a complement to the work of Monakow upon the relation of the thalamus to the cortex of the brain, has devised an instrument with which he is able to produce extensive lesions in the thalamus without any corresponding destruction in cortex. He studied the brains by making uninterrupted series of sections stained by the Marchi method. A number of animals were made the subjects of the experiments, and some interesting side results were obtained. For instance, the ascending degeneration of the fibers of the fillet after injury to the cervical cord stopped invariably at the optic thalamus. Fibers were also found passing from the thalamus to the cortex and other fibers passing from the cortex to the thalamus. The former group finally disappeared in the lower layers where they appeared to separate. Probably the cells or their neurons are found in the ventral nucleus of the thalamus. Other interesting points are that Meynert's band degenerates both upwards and downwards; the bundle of Vicq d'Azyr degenerates as far as the anterior nucleus; Forel's commissure degenerates toward a subthalamic region; Meynert's commissure, instead of passing to the lenticular nucleus enters the reticulated substance of the optic thalamus; the tegmental tract of the corpora mammillaria degenerates downward and terminates in the reticular substance of the

posterior corpora quadrigemina; after injuries to the **cerebellum**, a group of fibers degenerates toward the red nucleus and some of them terminate there, the majority, however, continue as far as the thalami. Probst, therefore, concludes that the **optic thalami** receive all forms of irritation from the periphery, from the spinal cord, and from the cerebellum, modify them or transfer them in some way, and then transfer them either to the cortex of the cerebrum, to the corpora quadrigemina, and perhaps to the red nucleus. He, therefore, regards the optic thalami as the chief modifying area between the periphery and the cerebral cortex. In conclusion he calls attention to some interesting observations made upon the crossed pyramidal fibers of the porcupine. These apparently split up as soon as they reach the spinal cord. The tegmental pyramidal group pass as far as the sacrum. [J.S.]

9.—(1) Riegel reports a case of **neurasthenia** in which transitory mydriasis occurred once or twice a year for the period of 12 years. As no organic change developed in this time he regards it as a symptom of functional disorder. (2) Bruns repels with energy the insinuation of Brodman that in his discussion of paralysis of the serratus muscle, he had made **serious errors** in his study of the cases reported in the literature. [J.S.]

11.—The patient, a man of 42, received a severe injury to the head. This resulted in more or less continuous headache, and there was a tender spot over the left ear. There was also a severe valvular lesion of the heart and some dyspnea. Six months after this injury, he suddenly developed a curious symptom, he became completely **word-deaf**, although his perception of sounds was perfect or even, as he claimed, slightly increased; his ability to speak or to read writing aloud was unimpaired. He described the condition as if persons spoke to him in a foreign language. There was no paraphasia. Five days later he had a severe attack of epistaxis and immediately was able to understand everything. Upon careful questioning, it was found that similar attacks of a still more transitory nature had previously occurred on one or two occasions. The heart-condition grew worse, the patient developed pneumonia and died. At the autopsy the interesting feature was the pronounced atrophy of the posterior portion of the third frontal convolution in the region of the pars opercularis. The first temporal convolution was small and there was a defect about its center on the under side filled with serous fluid. The sulci were much deeper than normal and on the right side a slight atrophy of the first temporal convolution could also be observed. Microscopically, there was found a general reduction in the elements in the atrophic gyri, but no focal lesion in the cortex or in the white substance. In analyzing this case, Veraguth calls attention to the following points: 1. The aphasia was secondary. 2. It must be regarded as subcortical on account of the nonimpairment of voluntary speech. 3. It was absolutely pure, no other disturbances of expression or of the perception of expression being present. The patient was able to understand gestures during the attack as well as ever. Finally, its transitory nature is particularly striking. Veraguth, after consideration of the cases already published, calls attention to the fact that a patient may have pure word-deafness without a subcortical lesion of

the left temporal lobe. In fact, there is some reason to believe that in order to produce this the lesion must be bilateral. The fact that during the attack the patient was able to recognize several sounds, such as the noise made by an induction coil, is sufficient proof that the hearing apparatus was intact, and it was found to be so at the autopsy. No method of staining in this case gave satisfactory explanation of the reason for the symptoms. Veraguth is therefore compelled to fall back upon hypothetic explanations and he supposes that there were some disturbance of circulation in the branch of the Sylvian artery going to the first temporal convolution. He concludes, however, that the primary substratum of pure word-deafness is not an interruption of the subcortical auditory tract in the white substance of the left temporal lobe, but a simple atrophy of the first temporal convolution, probably bilateral, associated with a secondary element either circulatory, toxic, or functional. [J.S.]

12.—Rybalkin reports the case of a man of 24, who had had convulsive attacks in youth in which he had bitten his tongue. When brought to the hospital in the last of these, it was found that he had a left hemiparesis, almost total anesthesia of the left side of the body, with hysteric stigmata—i. e., painful points over the left nipple and left hypochondrium and a hysterogenic zone back of the left ear. He occasionally manifested clownism. The diagnosis of **hysteric convulsions** was therefore made, and the biting of the tongue was ascribed to the clonic spasm of the lower jaw. Careful quantitative analysis of the urine showed that immediately after the attack there was great reduction in the solids and particularly in the phosphates. An inversion of the phosphate formula did not occur, so it may be concluded that only the first portion of the urine passed after the attack is characteristic for the hysteric attack, and that this consists of diminution of the phosphates and of their relation to the total nitrogen. [J.S.]

13.—von Rad reports the case of a boy of 14, who suddenly felt severe pain in both ears, which radiated into the face. In the course of 2 weeks complete paralysis of both facial nerves and a rightsided paralysis of the abducens appeared. In the course of a few days more there was paralysis of all the external muscles of the eye, with the exception of the levator palpebrae. The pupils reacted to accommodation and light. The muscles of the face gave the electric reactions of degeneration. The nerves, however, were not swollen, but the branches of the fifth were quite tender. The patient, 6 years previously, had an attack of what was diagnosed as tuberculous meningitis, which had left a slight paresis of the left orbicularis. Rapid recovery ensued and all the symptoms disappeared. It appears, therefore, to have been a **multiple neuritis** affecting only the cranial nerves. [J.S.]

14.—v. Bechterew reports a case of disease of the pons that presented a great number of interesting and unusual symptoms. The man was 28 years of age, an alcoholic, and had had luetic infection. He had an attack of vertigo with paresis of the right leg and arm, associated with difficulty in speech. There was exaggeration of the reflexes, otherwise no pronounced symptoms. There was rapid recovery and then subsequently another attack somewhat similar in character. Ultimately, however, there was persistent weakness in the right side and disturbance of speech. About a month after the first, there was a second attack in which there was almost complete **paresis** of the third nerve, of the muscles of the face, complete right hemiplegia, and left hemiparesis. There was frequent weeping. There was retention of urine and feces. The reflexes were enormously exaggerated. Later there was slight movement of the eye and gradual restoration of movement in the limbs. From time to time there was imperative laughing, and there was distinct **atrophy of the muscles** in the right leg. v. Bechterew discusses these symptoms at some length. The hemiplegia with crossed paralysis of the abducens locates the lesion in the posterior portion of the under surface of the pons. As in the early stages of disease there was some difficulty in swallowing, it is probable that the centers of the medulla were also involved. Later the lesion extended from the left to the right half of the pons. It is possible that the basilar artery was occluded by a thrombus giving rise to softening in this portion of the brain, although the rapidity with which the symptoms developed is rather in

favor of hemorrhage. It is impossible to mention all the points to which reference is made. The imperative weeping and laughing probably depended upon the situation of the lesion above the medulla, although we know very little about the portions of the brain that are associated with this symptom. It seems likely that the thalami have something to do with it. If we assume that the tract of fibers passing through the pons to the thalamus was involved, we can arrive at an explanation, not altogether satisfactory, not only of emotional disturbance but of a peculiar expiratory groan or cry that was a very constant symptom. The disturbance of speech he concludes is due to the involvement of a vocal center situated in the pons corresponding to the vocal centers found by Anodi in dogs, a slight distance back of the quadrigemina. The muscular atrophy is in all likelihood secondary to the cerebral lesion. There was no disturbance of the joint and apparently no other adequate explanation. von Bechterew is inclined to believe that in all likelihood this atrophy is brought about by some vasomotor disturbance. Why it should have affected only a circumscribed locality is to be explained by assuming a different degree of reaction in different tissues. [J.S.]

15.—Thoma reports a case of typical **multiple sclerosis** in which an autopsy was obtained. The tissue was stained by a variety of methods, in particular by the most recent neuroglia method of Weigert. No satisfactory method, however, exists for staining the axis cylinders. He mentions the theories of the different authors, that is, primary degeneration of the myelin sheaths, some inflammatory process, a primary disease of the true nervous substance, primary disease of the neuroglia, and, finally, the view that considers the whole thing secondary to vascular disturbance. As a result of the study of these sections, he reaches the conclusion that the whole nervous system may be involved. There is no proof of primary disease of the myelin sheaths or of true nerve tissue, but there is apparently in all the foci of disease proliferation of the neuroglia. Moreover, the foci of disease appear to commence in those situations in which the neuroglia is normally excessive. For this reason, the blood-vessels around which the neuroglia is usually in considerable quantity, appear to play an important part. Therefore he regards the entire process as due to a proliferation of the neuroglia. [J.S.]

16.—Frenkel has studied 23 cases of **locomotor ataxia**, all in the preatactic stage, and found that the patellar reflex was present in 11, the triceps reflex only in 8, and in 3 of these was unilateral. He therefore regards failure of the triceps reflex as even more characteristic of the disease than the failure of the patellar reflex. In a considerable number of these cases there was also marked exaltation of the mechanical irritability of the muscles, and he gives clinical reports of several cases in which this was the case. In general, it was tested by striking the muscular substance with a percussion hammer, causing a pronounced sharp contraction. In several instances this was sharply localized, thus in one case it was limited to the outer sides of the forearms. This increased mechanical muscular irritability appears to be due to the destruction of some reflex arc whose position is at present unknown. He also mentions among the other muscular conditions of locomotor ataxia, fibrillary twitchings, clonic contractions, muscular atrophies, and paresis of various groups of muscles, particularly the perineal group. All these muscular disturbances are probably secondary in nature. [J.S.]

17.—Möbins reports the case of a woman of 31, who at the age of 22 had an attack of **paralysis of the left eye** that was repeated thereafter at intervals for 2 years. This always commenced with severe headache in the region of the left eye, repeated vomiting, and then paresis of the head, followed, in the course of 24 hours, by total closure. The attack usually lasted about 2 weeks. When examined in the fifth attack, the eye was completely closed and the orbicularis palpebrarum appeared to be slightly spastic. The eye was directed downward and out. The pupil was widely dilated. There were no pupillary reactions and some hypesthesia of the conjunctivas and the surrounding skin. Nine days after the commencement of the attack there was slight elevation of the lid, and in 14 days the condition was very much improved. It was more than 2 months, however, before all the symptoms had disappeared. Möbins collected all the cases of this condition that have been reported and

notes the following clinical points: the attacks always commence with headache, which disappears as soon as the paralysis takes place; flimmer scotomas are never observed. Abortive attacks not infrequently occur. The duration of the attacks and their frequency vary considerably. The paralysis is always unilateral and is always total. Usually in the interval some slight symptoms of the paralysis are present. Möbius is of the opinion that some organic condition underlies the disease and that the recurrent attacks are due to a sort of an explosion, *i. e.*, the discharge of the accumulation produced by slight persistent irritation. The attacks may sometimes be confused with those due to true migraine, to tuberculous meningitis, and perhaps to aneurysms and other neoplasms. [J.S.]

18.—The patients were usually examined when lying on the back. The foot was grasped by the toes, elevated, and pressed upward. The point of election on the tendon varies slightly in different cases, but care must be taken not to strike the muscle-substance itself. There were 365 cases examined. The **Achilles tendon-reflex** was present in 356; it was absent on both sides in 3, and on one side in 6 cases,—more frequently in women than in men. The chief condition in which it was absent was apparently alcoholism; all the bilateral cases being of this nature and 2 of the unilateral cases. The other cases in which it was absent were phthisis, psoas abscess, and leukemia. Records from old cases of leukemia observed in the clinic failed to show that this condition existed in them. In 37 cases of sciatica, it was present in 22, weak in 5, and absent in 10. Those cases in which it was present appeared to have a more favorable prognosis. In 34 cases of tabes dorsalis it was completely absent in 30, absent on one side, and weak on the other in 3, and present in one case with loss of kneejerks. [J.S.]

19.—Oppenheim calls attention to the great importance of neuropathic diathesis in **intermittent claudication**. He believes that in some cases this may be the cause of the disease and therefore thinks the prognosis should not be regarded as hopeless. [J.S.]

1.—A soldier, 23 years old, was taken with symptoms of appendicitis. On opening the abdomen a large quantity of pus escaped, and as the appendix could not be easily removed it was not resected. After the operation there was escape of fecal matter, indicating perforation of the appendix; there was also intense jaundice. About 6 days after the operation the patient had a severe chill, his temperature rose and he perspired freely. The chills and the fever did not return, but the patient's general condition left much to be desired; 3 days later another collection of pus was located, and about a liter was evacuated through an excision under cocaine. The 2 wounds closed completely in a little over a month, but pain developed in the side of the chest. An abscess was located about the region of the ninth and tenth intercostal space and a large quantity of greenish pus was evacuated; at the bottom of the pus-cavity liver-tissue was found. Recovery followed and the patient left the hospital in excellent condition. A thorough discussion of the question of **suppurative processes of the liver** originating with the appendix follows. [M.B.T.]

2.—**Hematomyelia** may be primary or secondary. Secondary hematomyelia may be due to acute or chronic myelitis, syringomyelia, or tumors. Primary hematomyelia may be traumatic or spontaneous. The traumatic cases accompany fracture or dislocation of the vertebral column, or

the destruction of the vertebrae in Pott's disease; they may be due to indirect violence; they may be due to extension of the spinal cord, as seen in some patient's affected with tabes who have been treated by suspension, or to the elongation of the roots of the spinal nerves; or they may be the result of a medullary commotion or concussion of the spinal cord, as seen in violent electric discharges. Spontaneous hematomyelias are usually congestive and follow violent efforts, such as the spasms of whooping-cough or convulsive states; they may be seen in general hemorrhagic conditions such as hemophilia, infectious purpura, scorbutus, hemorrhagic smallpox, and pernicious anemia; and they may be due to vascular changes. Hematomyelia is sometimes due to the sudden relief from increased atmospheric pressure. In the latter class of cases Lépine thinks that gaseous embolus, producing a secondary hemorrhagic infarct, and gas, suddenly developing in the smallest vessels of the cord and producing rupture by its tension are both active in the pathogenesis of the lesion. The hemorrhage may be capillary or it may occur in larger or smaller areas. The area of hemorrhage is made up of several small clots that join areas of nervous tissue, more or less normal in character. The lesions are found most often and most numerous in the cervical enlargement; while in the thoracic portion of the cord the hemorrhage has a tendency to extend in length or in surface. As attending lesions, parenchymatous inflammation with or without vascular changes, meningeal effusion, and hemorrhage of the pia mater may be mentioned. The secondary hemorrhages are usually capillary. The hematomyelias produced by elongation and exaggerated flexion of the vertebral column are due to rupture of the vessels of the central substance. Those following medullary commotion present areas of congestive and small areas of extravasated blood. The personal studies of the author show that in the hematomyelia of sudden relief from atmospheric pressure there are hemorrhagic infarcts, and hemorrhages that follow the rupture of the small vessels under the influence of the sudden passage of gas from the blood. The immediate phenomena of hematomyelia are the formation of a clot of medium consistency which becomes dry and retracted. At the same time the axis-cylinders become swollen with corresponding changes in the myelin sheath. Then, if the clot becomes converted into fibrous tissue, the neighboring nervous tissue may not be greatly modified. In the majority of cases, however, the stage following hemorrhage is softening; later, the softened tissue is partly eliminated and lacunae are formed. There is ascending, descending, and peripheral degeneration, and the meninges may present reactional phenomena. In traumatic hematomyelia the beginning is usually instantaneous and paraplegia and anesthesia are complete. In the spontaneous hematomyelias the beginning is less sudden and the paraplegia and anesthesia develop slowly until they become complete and involve the rectum and the bladder. There is a tendency to collapse, and the temperature is below the normal. The gravity of the symptoms is more apparent than real. The paralysis and loss of sensation gradually improve until about the third or tenth week, when the symptoms become fixed. Then there is a more or less marked paralysis of both legs to which the descending degeneration of the pyramidal tracts adds a spasmodic character; atrophies occur; and the sensory symptoms may disappear altogether or they may be present in varied degree. In some cases death occurs soon after the hemorrhage. The clinical forms of the disease are (1) the central hematomyelias; (2) the syndrome of Brown-Sequard; (3) the cervical hematomyelias, and (4) hematomyelia of the conus medullaris. [J.M.S.]

3.—Bernard says that the **renal functions** are not uniformly disturbed in all cases of **chronic nephritis**. There are cases of nephritis in which the kidney is permeable or indeed in which it may present an increased permeability; there are other cases in which the permeability of the kidney is diminished. In the parenchymatous and the interstitial forms of nephritis the renal functions are differently disordered. Interstitial nephritis is a disease of slow evolution, characterized by a certain number of symptoms that are directly or indirectly dependent upon the disordered renal excretory function; in other words, the renal permeability is decreased from the first. From this diminished permeability we note 2 classes of phenomena: (1) Phenomena of intoxication by the retention of noneliminated

nated poisons and (2) mechanic phenomena. The mechanic phenomena are: (1) Cardioarterial hypertension, which is indicated by *bruit de galop* and modifications of the pulse; (2) histologic compensatory hypertrophy of the kidney, which, added to the hypertension in the arterial system and to the humoral conditions created by the renal permeability, determines polyuria. This fundamental symptom of interstitial nephritis has its origin in the renal impermeability, and, at the same time, it struggles against it avoiding the toxic effects. But the evolution of cases of interstitial nephritis presents some periods during which there is cardioarterial hypotension comparable to the paroxysms of asystole in the periods of compensation of cardiopathies. From this condition of hypotension we find: (1) Oliguria with augmentation of the intoxication by retention; (2) other modifications of symptomatology, such as more abundant albuminuria and edema. The pathogenesis of the edema seems to be the same as the pathogenesis of edema in chronic heart disease and its appearance may lend confusion by upsetting the table of chemitic symptoms of interstitial nephritis, while in reality it is only one phase of the disease. Parenchymatous nephritis presents a less insidious evolution and a symptomatology that is more indicative of the origin of the disease. The latter is dominated by edema and albuminuria and at this period the renal permeability is normal or even exaggerated. Then, when the disease is of a certain duration, the renal permeability diminishes; then to the preceding clinical picture phenomena are substituted or added, that, in interstitial nephritis, depend immediately or indirectly on the renal impermeability. This second stage corresponds to that which the English authors have called the period of secondary atrophy. The pathogenesis of uremic phenomena is, then, more complex than has hitherto been taught. It is not possible to establish an equation between renal impermeability and uremia, since the latter may exist without renal impermeability and *vice versa*. One should understand in the term autointoxication by retention only the series of phenomena that the author unites as the syndrome of renal impermeability. To this syndrome of impermeability he opposes a syndrome that we have thought a manifestation of insufficiency of the internal functions of the kidney, the existence of which, if not the mechanism, seems to be thoroughly demonstrated today. In this syndrome edema and albuminuria are placed and the union of the 2 syndromes constitutes renal insufficiency; but renal insufficiency is not able alone to provoke uremia; it is dependent upon secondary affections of the heart, the lungs, or the liver, so that the functions of these organs become insufficient. From the diagnostic viewpoint the 2 methods of investigation of the excretory function of the kidney that are of certain semiologic value are the proof by methyl-blue and the study of the toxicity of the urine. The toxicity of the serum, which is not in proportional relation with the toxicity of the urine, does not give exact evidence of the functional state of the kidneys nor of the humoral condition of the organism; finally the urinary elimination depending partly upon the humoral state, the chemic analysis of the urine gives only incomplete results. [J.M.S.]

4.—By experiments on tuberculosis in dogs Richet has established the following points: 1. Raw meat will prevent the development of tuberculous infection and will induce cure. 2. The quantity of raw meat necessary and sufficient is about 12 gm. per kilogram of bodyweight. 3. Muscle plasma extracted from the meat contains the active principles of the substance. 4. Cooked meat does not act as raw meat and the effect of treatment by the latter substance is not due to superalimentation. The meat must be prepared according to the method advanced by Fuster in 1865. The meat is made into a pulp by pounding it in a mortar; this pulp is then passed through a fine sieve and is made into boluses and rolled in sugar. Fuster combined with the raw meat thus prepared an alcoholic drink composed of 100 gm. of alcohol, 250 gm. of water, and 60 gm. of syrup. Richet believes that experiments on dogs show that **raw meat** is not a food but a medicine and that it acts by virtue of the enzymes, ferments, and unknown diastases that it contains. The author recommends that raw meat be used in the **treatment of tuberculosis** in the human subject as a deduction from his animal experiments. He does not claim that the results will be certain. Raw meat should be given in doses of 600 to 750 gm. daily; and, if only the muscle plasma is given,

this should represent 1,000 gm. of raw meat. It is not necessary to reserve this treatment for those patients that suffer from gastrointestinal disturbance; but it should be used as a **remedy on account of its antitoxic action.** [J.M.S.]

The Effects of X-Rays on Cultures of Microorganisms.—Wolfenden and Forbes-Ross (*Archives of the Röntgen-Ray*, August, 1900) report the results of two years' study of this subject. They find it impossible by any ordinary long exposure to high vacuum tubes to kill growths of bacilli or cocci by x-rays. The x-rays stimulate the germination of seeds and fermentative processes and these effects are also produced in cultures of bacilli, the vegetative properties of which are stimulated to excessive growth, while they are profoundly altered in their biologic and physiologic characters. An apparent death in cultures so treated is only due to exhaustion of vitality from excessive proliferation since only rest is required to enable the organisms to again take an active growth. [M.B.T.]

Stricture of the Esophagus.—Bunts (*Cleveland Journal of Medicine*, September, 1900) describes a series of graded, olive-shaped bougies he had devised to overcome esophageal strictures following upon the accidental swallowing of lye. On each staff there are two bulbs, the first being one size of the French scale smaller than the second bulb. This serves to permit following up the advantage gained by passing one bulb by the immediate passage of one a size larger. Sometimes it will be impossible to increase these sizes more rapidly than one or two of the French scale in every three or four days, at other times we may succeed in dilating it a number each day. Much depends upon the degree of stricture and the depth of the original injury. Great gentleness and care are required, and if one meets with repeated lack of success in one day it is better to allow the patient to rest for a day or two, if his state permits it, and then try again. It is best to have the patient sit upright in a straight-backed chair, the head thrown back somewhat, in order to straighten the line of introduction of the bougie. Instead of passing it directly back in the median line it is probably better to pass it into the pyriform sinus at the side of the larynx, which affords a funnel-like aperture that will allow the bougie to slide into the esophagus without encountering the bodies of the cervical vertebrae or the cricoid cartilage. Force should never be exerted. [G.C.C.H.]

Hemorrhage Occurring After the Menopause.—E. C. Davis (*Obstetrics*, September, 1900) thinks that as the menopause is a physiologic condition, it should be entered upon by a woman with normal generative organs without pathologic disturbances. It is at this time that atheromatous changes are likely to take place in the bloodvessels, malignant diseases make their appearance, and the atrophic changes of the tissues become observable. When the menstruation has ceased and the menopause been reached, any hemorrhage from the uterus is always pathologic, and should be carefully investigated to determine its cause, while the prospects of relief are favorable, even though it originates from a grave condition. The causes of hemorrhage at this time are: (1) Granular endometritis; (2) atheroma of uterine bloodvessels; (3) vasomotor relaxation; (4) uterine polypus; (5) uterine myofibromas; at the menopause, fibromas are said often to disappear through some retrograde change, and no doubt they occasionally decrease in size, but more often they continue to increase in size, and to threaten the life and health of the patient by the continuation of the hemorrhage, in addition to the possibilities of sloughing, and infection of the tissues, through the putrefactive changes taking place in them while breaking down, and affecting the contiguous tissues; (6) carcinoma of the uterus. The cervix is the most frequent seat of the disease, and epithelioma is the most common form of malignant tumor. An epithelioma, as is well known, when completely removed before the invasion of the surrounding tissues, is less likely to return than any other form of malignant tumor. Malignant disease rarely attacks the nulliparous uterus, or one in which there has not been one or more decided tears, and in which there is not much indurated cicatricial tissue. Hence the importance of repairing promptly these tears, and of the complete removal of this weak scar-tissue formed in the cervix. [W.K.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Treatment of Dyspepsia.—The *Medical Review*, London, July, 1900, quotes T. Lauder Brunton (*Clinical Journal*, April 25, 1900) as stating that the first rule for the patient who suffers from indigestion is, eat slowly, masticate thoroughly, insalivate completely. Many patients will say that they eat slowly, yet they do not masticate thoroughly. If the patient will not, of his own accord, follow the rule, he must, if necessary, follow Sir Andrew Clarke's rule—count the bites. For every mouthful of meat he must allow 32 bites, or one bite to every tooth. If the meat is tough he must allow 64 bites, and if very tough, 96 bites.

The next rule is, Let the patient take his solids and liquids separately. The reason for this is that if a patient with a weak digestion swallows much liquid—whether it be soup, plain water, mineral water, whisky and water, or beer—he dilutes his gastric juice, and thus lessens its digestive power. So it is better for a patient, who has weak digestion, to take his food without liquid. One meal, however, may be made an exception, and that is breakfast, because the food is generally of a soft and chiefly farinaceous character, and therefore a little more latitude may be allowed. But there is another reason for making the patient take food and liquid separately, and that is that unmasticated food cannot be swallowed without liquid. So that, even at breakfast, tell the patient that he can, if he likes, take a breakfast cupful of tea, not strong, but towards the end of the meal. Of course the gastric juice is diluted by the tea, but this does not matter so much in the case of farinaceous food as in the case of luncheon and dinner, into which proteids enter largely.

In many cases those rules are sufficient to remove dyspepsia. But in cases where they are insufficient, the third ones comes into play: Let the patient take his farinaceous foods at different meals. That is to say, he may take bread and butter for breakfast, but he must take neither fish, eggs, nor meat. In the middle of the day he must take fish, eggs, or meat, but no farinaceous food whatever. At about 5 o'clock he should again have a farinaceous meal, such as he had a luncheon. Only food of the same kind is put into the stomach at each meal, and so there is no delay from the different digestibility of the different kinds of food, the whole contents of the stomach become comminuted and digested and passed on into the intestine about the same time. Under those three rules a great number of dyspeptic patients can be cured.

But patients must have some fluid. The best liquid they can drink is hot water, and the best times to drink it are on rising in the morning, again between 11 and 12 in the forenoon, again about 4 or 5 in the afternoon, and, lastly, at night before going to bed. Thus the patient is given all the fluid he requires, not when it will dilute the gastric juice, but when it will assist in washing out of the stomach the remnants of the previous meal. Given at 12 o'clock, it tends to wash the breakfast out of the stomach, at 4 it washes out the remains of the luncheon, and so on.

In cases where the stomach is weak it may be an advantage to supplement the normal gastric juice by giving some acid and pepsin; and, apparently, there is sometimes an advantage in giving mixed enzymes—not pepsin alone, but pepsin containing rennin. Just before meals it is often advisable to give a little alkali, which tends to stimulate the secretion of gastric juice. The common way of giving this stimulant is with some bitter, containing no tannin, such as calumba; and this seems useful when the stomach is not irritable, and when there does not seem to be much catarrh. But if there is much catarrh in the stomach better results are often got from substances containing tannin, such as the infusion of gentian; and in patients with a flabby tongue perchlorid of iron combined with quassia is often useful. When the tongue is large, pale, flabby, and marked by the teeth at the edges, better results are sometimes got from quassia and iron than from pepsin and other remedies.

In some cases, when the habit of taking large meals or drinking large quantities of water has led to dilation of the stomach, the plan of taking fluids and solids at separate

times very often aids greatly in restoring the normal condition. But when it does not, then the use of a soft rubber tube to wash out the stomach either every morning on rising, or every night before going to bed, will often help very greatly. In cases of permanent dilation of the stomach due to pyloric contraction, the only remedy is gastroenterostomy.

Vomiting of Acute Gastritis.—

R.—Wine of ipecac..... } of each.....½ ounce.
Tincture of nuxvomica..... }

Sig.—Two drops in water every 2 hours.

Heroin in Coughs.—McGee (*Cleveland Journal of Medicine*, June, 1900) states that while heroin possesses hypnotic and analgesic powers it especially excels in controlling cough without the coincident disadvantages of morphin. Heroin resembles codein in effect and range of action, but excels it in the smaller dose required, and perhaps, too, in being better borne. The author prefers the soluble chlorid in doses of $\frac{1}{32}$ to $\frac{1}{16}$ of a grain. This amount every 2 or 3 hours has generally proved sufficient to relieve nervous and irritating cough without exciting unpleasant symptoms. In these doses it seems a safe and satisfactory remedy. One-sixth of a grain probably represents the safe adult dose, and for children, to whom it has been mainly given in pertussis, the average doses are from $\frac{1}{100}$ to $\frac{1}{50}$ of a grain. Like other opium preparations, however, children are quite susceptible to its action, and with them its action should be closely watched. Heroin seems especially adapted to quiet coughs of a nervous and asthmatic character, as well as those of reflex origin, and expectoration is probably easier under its influence. It is more certain than codein, safer and less disagreeable than morphin, and, unlike the latter, it is said to stimulate rather than depress the respiratory center.

An Antiseptic Varnish for Replacing Collodion.—

According to the *Journal des Praticiens* for August 18, 1900, the following combination makes a useful substitute for collodion:

R.—Thymol.....24 grains.
Balsam of tolu80 grains.
Pulverized gum lac.....15 drams.
Alcohol (90%).....6½ drams.
Ether.....13 drams.

Fersan.—According to Silberstein (*Therapeutische Monatshefte*, July, 1900), this new ferruginous preparation is prepared by the action of concentrated hydrochloric acid on red blood-cells, the latter being separated by centrifugalizing blood. It appears as a brown powder with a slightly salty taste, and it does not coagulate on heating. The author has administered it in various forms of anemia with good results. The dose is about 3 to 6 teaspoonfuls daily, although much larger amounts have been given without bad effects. The new preparation is said to be free from the untoward effects of other ferruginous compounds. As fersan is not affected by artificial gastric juice it is surmised that it is absorbed only from the intestine, and the fact that the stools are not blackened as by other iron salts is offered as proof of its complete absorption.

Acute Diarrhea:

R.—Tannalbin.....1½ drams.
Pulv. opii2 grains.
Bismuth beta-naphtholate1 dram.

Make into 12 powders. One every 2 hours.

Substances Which Should Not Be Prescribed in Cachets.—According to Bricemoret (*Bulletin of Pharmacy*, September, 1900), there are three groups of substances which should not be prescribed in cachets: The first of these includes substances readily absorbing the moisture of the air—sodium bromid and iodid, crystallized calcium chlorid, strontium bromid, iron ammonia-citrate, piperazin, chloral, dry vegetable extracts prepared by evaporation *in vacuo*, and extracts of animal organs desiccated *in vacuo*; the second group includes mixtures which form fluids—mixture of antipyrin and sodium salicylate; the third group consists of substances which are decomposed by the oxygen of the air and the products of the decomposition of which stain the cachet—alkaline and ferroalkaline iodids and the aristols.

The Medicinal Treatment of Menstrual Disorders.—H. Macnaughton Jones (*Edinburgh Medical Journal*, July, 1900) states that he has found senecio very useful in both amenorrhea and dysmenorrhea, the dose being from 2 to 6 grains. It may be given alone or in combination with hydrastis or hydrastin, which latter drug has proved beneficial in congestion and spasmodic dysmenorrhea, especially when administered in combination with bromids. *Piscidia erythrina* (1 to 2 grains) has been found useful in combination with hydrastis and viburnum in dysmenorrhea and menorrhagia. Hydrastin hydrochlorate is one of the most valuable hemostatics in hemorrhage, especially in the following combination:

R.—Hydrastin hydrochlorate $\frac{1}{2}$ grain.
Ergotin $\frac{1}{4}$ grain.
Cannabin tannate..... $\frac{1}{2}$ grain.
Stypticin $\frac{1}{2}$ grain.

Cornutin hydrochlorate ($\frac{1}{2}$ to $\frac{1}{4}$ of a grain hypodermically) has been used alone or in combination with ergot in menorrhagia and other forms of uterine hemorrhage. *Cimicifuga* has been efficient in hemorrhage dependent upon uterine subinvolution. In anemic conditions maganese is esteemed as an emmenagog, especially in combination with iron, quinin, arsenic, and nuxvomica. Of the coaltar preparations, antipyrin has been most successful in dysmenorrhea. In those cases of amenorrhea or dysmenorrhea dependent upon mitral stenosis, strophanthus and digitalis are indispensable. In menorrhagia they can be given with hydrastis and ergotin. Morphin in dysmenorrhea is considered dangerous; codein, exalgin, butyl-chloral, and bromids are recommended as substitutes. The following sedative application over the ovarian region is highly spoken of:

R.—Extract of belladonna..... 2 drams.
Camphor..... 2 drams.
Mastic 3 drams.
Chloroform } of each..... 2 ounces.
Tincture of aconite }

In ovarian congestion the following counterirritant is recommended:

R.—Iodin..... 1 dram.
Mastic 1 dram.
Rectified spirit..... 1 ounce.

Acute Cystitis:

R.—Tincture of hyoseyamus..... 6 drams.
Fluid extract of lupulin..... 6 drams.
Fluid extract of uva ursi..... $1\frac{1}{2}$ ounces.
Solution of potassa 2 drams.
Sirup to make..... 6 ounces.

A tablespoonful every 4 hours.

Acute Rheumatism.—Nestor Tirard (*Medical Treatment of Diseases and Symptoms*) speaks favorably of the following application:

R.—Salicylic acid }
Oil of turpentine } of each..... 3 drams.
Lanolin }
Lard sufficient to make..... 3 ounces.

Apply to the painful parts, cover lightly with cotton-wool, and renew night and morning.

Quinate of Piperazine.—Blumenthal (*Bulletin Général de Thérapeutique*, May 15, 1900) states that favorable results have been obtained in Leyden's clinic with this new uric-acid solvent in various gouty disorders. The daily administration of from 75 to 120 grains of quinate of piperazine caused a decrease of from 40 to 50% in the amount of uric acid in the urine, hippuric acid appearing instead. The persistent diminution of uric acid and the presence of hippuric acid indicate that that drug does not merely retard the elimination of the uric acid, but in part inhibits its formation and so affects metabolism that a soluble product is made to replace an insoluble one. Meyer has employed quinate of piperazine in 10 cases of gout—5 arthritic, and 5 associated with renal gravel. No other remedies were administered, and in all cases a favorable influence was observed. In the cases of uric-acid gravel there was a marked diminution in the quantity of uric acid excreted in 3 cases, and complete disappearance in two. Ewald has employed this drug in 3 cases of renal gravel associated with

considerable irritation of the kidneys. The daily dose was 75 grains. In all of the cases the urine rapidly became clear and remained so for some time after the remedy was discontinued. Goldscheider and Fraenkel also report successes with the drug in gout.

Urticaria.—The *Journal des Praticiens* recommends the following lotion:

R.—Ethyl alcohol
Sulphuric ether } of each..... 1 ounce.
Chloroform
Menthol..... 10 grains.

The Treatment of Cystitis.—Foster (*St. Paul Medical Journal*, No. 2, 1900) states that in acute cystitis rest in bed should be insisted upon, and the diet should be liquid or semisolid, all stimulating articles of food and drink being forbidden. Large quantities of bland liquids, as soup, milk, koumyss, and alkaline liquids are usually grateful to the patient, and are to be advised. The bowels should be freely opened, by blue mass or calomel, at the beginning of treatment, and should be kept active during the continuance of the disease. This is important for the purpose of keeping the alimentary canal as free as possible from microorganisms and their products, and also because constipation and straining at stool increase the congestion about the bladder. When the urine is highly acid, alkalies are indicated, and the most useful is the solution of potassa. It may be administered well diluted and mixed with a little mucilage. A convenient formula is:

R.—Solution of potassa 2 drams.
Mucilage of acacia..... 1 ounce.
Tincture of hyoseyamus to make..... 4 ounces.

Sig.—One teaspoonful every 4 hours.

If the urine is already alkaline, and particularly if it is ammoniacal, we should prescribe urinary antiseptics, as salol, boric acid, or sodium benzoate. Perhaps the most reliable antiseptic is urotropin.

Washing out the bladder with various antiseptic solutions is useful. When the patient cannot completely empty the bladder this washing must be done through a catheter in order that the fluid may be entirely withdrawn; but when there is no obstruction this washing had best be done by means of hydrostatic pressure. The solutions which the author has found most serviceable are silver nitrate, corrosive sublimate, salicylic acid, and potassium permanganate. The solutions should be hot, and enough should be introduced at a time to thoroughly distend the bladder, so that all parts of the mucous membrane may be reached by the fluid. In very acute cystitis, where tension of the mucous membrane is contraindicated, washing out of the bladder cannot be practised, and it is in these cases that we derive great benefit from the method of instillation first adopted by Guyon. This consists of injecting a few drops, 25 to 50, of a stronger solution than is used where the bladder is washed out. Silver nitrate is universally admitted to be the best for this purpose, and may be used as strong as a 5% solution. It is best to begin with a 1% solution and gradually increase the strength. I usually employ for this purpose a solid silver catheter with a very fine bore, attached to a graduated glass syringe. The bladder should be completely emptied and the fluid introduced drop by drop, the tip of the catheter being just at the neck of the bladder. Rovsing, in his recent work, speaks highly of a modification of this method, which consists of washing out the bladder with sterile water and then introducing about 2 ounces of a 2% solution of silver nitrate, and, after a couple of minutes, introducing the same amount of sterile water. This leaves in the bladder a 1% solution of silver, which, after a time, the patient passes himself.

When the bladder cannot be completely emptied by the patient, particularly in chronic cystitis, the bladder must be drained either through the urethra or by means of an artificial opening. Drainage by means of a catheter through the urethra often gives great relief to the patient, and sometimes brings about rapid improvement. It is especially indicated in cases in which the shape of the bladder has not been altered, and in which there has not been much loss of tone in the muscular coat, and in which unusual sensitiveness of the urethra does not immediately resent the presence of a foreign body.

PANCREAS AND SPLEEN. CASE III.

Original Articles.

HEMORRHAGIC PANCREATITIS AND FAT-NECROSIS FOLLOWING AN OPERATION ON THE GALL-BLADDER.

By CHARLES G. STOCKTON, M.D., AND HERBERT U. WILLIAMS, M.D.,
of Buffalo, N. Y.

In the history of this unusual case some interest attaches to the repeated attacks of cholecystitis and to the accompanying gallstones, but in the following considerations only so much of the history of the diseased bile-passages will be given as relates to the subsequent hemorrhagic pancreatitis.

The patient, Mrs. R., a widow, 66 years old, had cholecystitis 6 years ago and again 4 years ago, this time with severe hepatic colic and jaundice. She made slow improvement and sustained a relapse six months later. There was no vomiting or nausea following this and she slowly improved in most respects until late last autumn. She had been a stout woman and now regained most of the weight that she had previously lost. There was no recurrence of jaundice nor was there evidence of troubled digestion, but during these years she suffered from frequent attacks of pain in the hepatic region. The pain was never severe enough to require anodyne, although hot applications were often made and she felt that she was not entirely well. About the middle of October, 1899, she fell and sustained a slight strain of the body, after which the pains became worse. About the first of December, although the pain had recently somewhat diminished, she became slowly jaundiced, suffered from much gastric distress with stools at times clay-colored, at other times showing some bile-staining; the urine became beer-colored and there was progressive loss of weight.

She was examined by Dr. Stockton on January 20, 1900, at which time she complained of dull pain in the small of the back and occasionally in the hepatic region. She had moderate jaundice, clay-colored stools and fair gastric digestion. There was total acidity of 30, combined chlorids 10, acid salts 5, and free hydrochloric acid .05. There was no gastric catarrh and the food showed good digestion. The urine was acid, dark reddish color, specific gravity 1.023, showing a trace of albumin, bile coloring-matter, no sugar, a trace of indican, the total amount in 24 hours 480 cc with 7.84 grams of urea. Microscopically there were found a few bile-stained, finely granular casts, squamous epithelium, leukocytes and cylindrical. The liver was palpable, about one inch below the free costal border and was smooth and lightly tender. The gallbladder could not be felt.

The diagnosis of cholecystitis and cholelithiasis was made. She was judged not to be in a condition suitable for operation and was therefore sent to the Buffalo General Hospital to be treated by vapor baths, limited diet, hot fomentations and large draughts of water. Under this treatment she made moderate improvement in most respects and more especially in the condition of the urine. The casts disappeared, as did the biliary coloring-matter, with the subsidence of the jaundice.

On February 14 she was allowed to sit up and walk a little about the room. Immediately afterwards her temperature rose to 101° F., the pulse to 100 and at the same time there was an increase of pain and a return of the jaundice. An operation was now resolved upon. This was performed on the 21st of February by Dr. Roswell Park, and is kindly described by him as follows:

"After opening the abdomen by an S-shaped incision, the gallbladder was found extremely contracted and drawn up beneath and behind the anterior border of the liver. In it could be felt at least one calculus, while along the duct others could be felt. The operation was made extremely

difficult by the fleshiness of the patient and by adhesions as well as by the deep situation of the gallbladder and the duct. During the manipulation required for making access to these, especially to the latter, I was perfectly conscious that more or less of damage was being done to adjacent structures, but was absolutely unable to estimate it. One calculus was removed entire from the gallbladder, while most of the material in the duct had to be crushed before it could be removed with a spoon. The impacted stone, which seemed to be producing complete obstruction of the duct, was at least half an inch in diameter. Several small calculi were also removed. The material thus obtained weighed 4 grams. Sutures were applied as carefully and as accurately as was possible under the difficulties, and a small drain inserted into the gallbladder."

The patient bore the operation well, but soon afterwards required stimulants. During the afternoon and evening she suffered severe pain, requiring anodyne. Early in the morning there suddenly developed a condition of shock, the pulse being 140 and thready, temperature being 102. The patient was given an intravenous injection of normal salt-solution, hot enemas and hypodermic stimulation, after which there was temporary improvement, but death ensued about 3 P.M., 28 hours after the operation.

A clinical diagnosis of septic peritonitis was made, but this did not seem sufficiently extensive to account for the sudden development of the shock and the early, fatal termination of the case.

Autopsy by Dr. Williams, February 22, 1900, two hours after death. The subject was a somewhat stout, middle-aged woman. There was an incision 12 cm. long in the right hypochondriac region, approximately parallel with the costal margin. The end of a rubber drainage-tube projected between the edges of the incision, which was closed with silkwormgut sutures. The whole was covered with a bandage and dressing. The subcutaneous adipose tissue was 1½ cm. in thickness over the thorax, and 3 cm. over the abdomen. There was some arteriosclerosis and calcification of both coronary arteries; otherwise the heart and pericardium as well as the pleural cavities and lungs were not remarkable. The omental and mesenteric adipose tissue was well developed. The peritoneal cavity contained a quantity of dark, serous fluid. The peritoneal surfaces of the intestine and liver were covered with a thin layer of fibrin. The coils of intestines were congested. The spleen was more than twice its normal size, dark and soft. The kidneys, ureters, and suprarenal bodies were not remarkable. The mucous surfaces of the stomach, the duodenum, and the remainder of the intestines, with the vermiform appendix, presented nothing noteworthy, except a small, clean-cut round ulcer on the posterior wall of the duodenum, just below the pylorus. There was a firm fibrous adhesion between the lower anterior margin of the liver and the anterior abdominal wall above the umbilicus. The liver was of about the normal size and was hard, its capsule thickened, its surface coarsely granular, in color pale and yellowish; the lobules distinct on section. The drainage-tube above mentioned entered the gallbladder, which was contracted, and passed through the cystic into the common bile duct, ending 2 cm. from the bile-papilla. The lower end of the tube was secured to the wall of the duct by a purse-string silkwormgut suture. The bile-papilla was prominent. The submucous layer of the duodenum in this region was thickened and red from infiltration with blood.

The pancreas was large and showed well-marked fatty infiltration. The pancreatic duct was easily found, opening inside the bile-papilla, and was large and patulous. The head of the pancreas was enlarged; it was firm and dark reddish-brown in color. On section it showed irregular, chalky-white areas, alternating with dark areas, apparently of hemorrhagic infiltration. Incision into the body of the pancreas near its middle showed some small hemorrhages in this vicinity. On both surfaces of the pancreas, but especially the posterior, there appeared numerous round, flat, firm, opaque, white areas, 1 to 5 mm. in diameter, plainly seen in contrast with the normal adipose tissue. They

were regarded as fat-necroses, which they proved to be on examination with the microscope.

The lymph-nodes in the neighborhood of the pancreas were slightly enlarged, firm, and pink in color. It was unfortunately not possible to examine the solar plexus, as the time allowed for autopsy was limited.

Histological Examination.—The fat-necrosis presented the usual characters of these lesions. There was no marked accumulation of leukocytes or other cells around them, and no increase of connective tissue. They were identical in appearance with those seen in the hog and those produced by operations on the cat. Large amounts of calcium salts were present in them, which is interesting taken in connection with the clinical history.

The mucous membrane of the duodenum showed nothing remarkable. The capillaries of the submucous layer close to the pancreas were distended with blood. The lymph-spaces of this layer contained numerous red blood-cells, and in some places were crowded with them. There were no large hemorrhages.

The pancreatic duct and its branches possessed an intact epithelial lining. The ducts were usually empty, sometimes they held stringy contents, probably mucus. Sections of the pancreas showed fatty infiltration, and rather more abundant connective tissue than is usual, in which "mast-cells" and a few plasma cells (Unna) were seen. In osmic acid specimens slight fatty degeneration of the glandular epithelia became evident. Areas of fat-necrosis were numerous in the interlobular adipose tissue. Leukocytes occurred in the stroma of the pancreas, between the groups of acini, in moderate numbers, both in the body and the head of the pancreas. There were points on the surface of the head where masses of leukocytes and fibrin with much granular detritus were seen. Numerous hemorrhagic areas appeared in and about the head of the pancreas. Small hemorrhages occurred both in the body and head of the pancreas. Rarely small veins containing recent thrombi were observed. The dark color of the head of the pancreas was partly due to necrotic fat-cells, whose contents were stained orange-red, apparently from the imbibition of blood-coloring matter. Masses of decolorized blood-corpuscles were also noted. Occasionally the necrotic fat-cells contained granules and rod-shaped crystals of brown pigment, and a similar pigment occurred between the fat-cells.

In the head of the pancreas numerous ill defined areas occurred, in which the epithelial cells were shrunken, their nuclei staining badly. There were other areas in which the outlines of the epithelial cells were indistinct, and the nuclei took no stain at all. These changes were not marked. They were often seen in close contact with necrotic fat-cells.

The histological examination of the other organs of the body yielded no results appearing to have any relation with the condition in the pancreas.

Bacteriological Examination.—The bacteriological examination gave the following results: The peritoneal fluid, the liver and the pancreas contained an organism in pure culture, which in regard to motility, staining by Gram's method, growth in gelatin and agar plates and tubes, growth on potato, coagulation of milk, fermentation of glucose, and development of indol, corresponded with *Bacillus coli communis*. A tube made from the pancreas and kept in the incubator under anaerobic conditions, showed no growth. A tube made from the spleen showed no growth. In sections of the pancreas, a few short bacilli with round ends, staining with methylene blue, were seen, but they did not appear to have any relation with the fat necrosis. Considering the circumstances of this case, the presence of *Bacilli coli communis* appears to have no special significance.

Conclusions.—There was no evidence of any obstruction in the pancreatic duct or any of its branches. Acute interstitial inflammation of the pancreas with hemorrhage was present. The other lesions in the pancreas were fat-necrosis in the surrounding and interlobular adipose tissue, and necrosis of some parenchymatous cells. In the opinion of the writers the pathological conditions are best explained as having resulted from traumatism to the pancreas sustained at the operation and unavoidable on account of its diffi-

culties. (See Dr. Park's description of the operation.) That such traumatism occurred is indicated by the hemorrhages in the head of the pancreas and in the adjacent submucous layer of the duodenum. The lower end of the drainage-tube in the common duct was only 2 cm. distant. A disturbance of the tissues of the head of the pancreas would account for the necrosis of the parenchymatous cells, and would make escape of the pancreatic ferments possible. Fritz has reported a case (*Boston Medical and Surgical Journal*, 1892, Vol. cxxvii, p. 571) in which pancreatitis and fat-necrosis resulted from an injury, and a case resulting from a crushing injury, received in a railroad accident in which the pancreas was ruptured, is reported by Schmidt, *Münchener medizinische Wochenschrift*, May 8, 1900. The significance of the pigment crystals in the head of the pancreas, and partly inside of necrotic fat-cells, is not clear. They must have been due to imbibition of blood or bile coloring matter, possibly though not probably from an earlier lesion; chemical tests gave indecisive results. It is possible that the beginning of the affection coincided with the rise of temperature and pulse noted in the clinical history as occurring shortly before the operation. That is unlikely, however, as none of the classical symptoms of pancreatitis were present at that time.

Explanation of Plate.—Pancreas showing numerous small fat-necroses in the adipose tissue about it; the head of the pancreas is somewhat enlarged and is dark brown in color from hemorrhage; part of the stomach, just entering the duodenum, appears above and behind the head of the pancreas; the spleen and body of the pancreas have been given one-half turn, so that their posterior surfaces are shown, and the upper border of the spleen appears in the sketch as the lower.

OBSTRUCTION OF THE COMMON BILE-DUCT.

By JOHN B. DEEVER, M.D.,

of Philadelphia.

WHILE the subject of this paper—obstruction of the common duct—deals with but a portion of the numerous conditions met with as a result of interference with the channels for the outflow of the bile, yet obstruction of the common duct is comparatively of such frequent occurrence that a consideration of the etiology, pathology, symptoms, diagnosis, and treatment must interest all of us.

The etiologic factors in the production of obstruction of the common duct may be divided into two varieties, those occurring from causes within the duct and those from external causes. The most common intrinsic cause of obstruction is gallstone. Stenosis and occlusion secondary to the passage of gallstones are rarely met with. Round worms have been found so closely packed in the common duct that they have completely closed its lumen. Two specimens of this character are in existence—one in a Paris museum and a second in the Wistar-Horner Museum at the University of Pennsylvania.

The extrinsic causes of obstruction of the common duct are carcinoma of the head of the pancreas, duodenum or pylorus, an aneurysm of one of the branches of the celiac axis, a floating kidney, a retroperitoneal growth in this particular region, or enlargement of the lymphatic glands situated in the gastrohepatic omentum.

The pathologic causes of obstruction of the common duct, whether due to inflammatory invasion or from malignant disease of the duct or adjacent viscera, do not present features dissimilar to the same condition elsewhere.

The inflammatory process excited by the presence of a stone in the duct is shown at first by the outpouring of mucus, hypersecretion, with congestion of the mucosa; acute thickening of the lining of the duct follows, and later the entire coats of the duct become infiltrated and a purulent exudation occurs, which is followed by ulceration.

In chronic disease of the duct, stricture occurs as a result of contraction of the inflammatory deposit in the walls of the duct. The lower portion of the duct is the part most commonly attacked by the inflammatory process, on account of the close proximity of the duct to the bowel and its communication therewith, and the presence of the multitude of bacterial inhabitants in the bowel. The bacteria most commonly found present in inflammatory disease of the duct are the *Communis coli* and the streptococci. Primary carcinoma of the common duct is not common. The duct is usually involved secondarily to disease in the head of the pancreas, duodenum, or of the stomach.

The symptoms vary according to the character and cause of the obstruction to the duct. The symptoms of an acute obstruction are marked by sudden onset of colic, nausea or vomiting or both, pain, tenderness, in some instances, collapse, and jaundice.

The colic in obstruction is due to the effort of the duct to expel its contents, and is analogous to the colic in appendicitis. If the foreign body is fixed at the duodenal end of the duct, the colicky pains may become continuous and only cease after the stone has become expelled into the bowel, or when it drops back into the duct, as in the ball-valve action of a stone, as described by Fenger. Coincident with the acute seizure of biliary colic there is associated therewith violent and agonizing pain in the region of the liver, which may radiate to the right shoulder. The pain may as likely be referred to the epigastrium or to the umbilicus. A line drawn from the tip of the ninth rib to the umbilicus and bisected at its midpoint by another line drawn at a right angle would approximately represent the position of the common duct. The rigidity and tenderness early in the disease would be confined to this line. The pain is sometimes referred to the lower chest-wall.

The tenderness in obstruction of the common duct is marked upon slight and superficial palpation, and if the obstruction is associated with cholecystitis, the tenderness is so pronounced that the merest contact with the abdomen will reveal it.

Rigidity of the right rectus muscle early in inflammatory and obstructive disease of the common duct is pronounced and can be elicited by barely bringing the finger-tips in contact with the abdominal wall. Very much more can be learned in the examination of the abdominal wall by gentle manipulation than by any other means. Rigidity of the flat muscles in the upper right quadrant of the abdomen occurs as a later manifestation. Nausea and vomiting are of reflex origin.

The temperature is of considerable importance in certain cases of obstruction of the common duct. In recent or acute cases of obstruction, an increase of temperature indicates the onset of the inflammatory stage; in chronic cases an irregular intermittent temperature is pathognomonic of the presence of gallstones.

The collapse which at times occurs at the onset of acute obstruction of the common duct is principally of reflex origin, although it may presage rupture of the duct.

Jaundice is not a constant symptom of obstruction. If the obstruction is of short duration, then jaundice will be absent, as in acute inflammatory edema of the mucosa, or in temporary but complete obstruction.

Permanent obstruction, whether from the presence of a stone or from malignant disease, is always accompanied by jaundice; in the latter instance it is progressive.

The importance of being able to differentiate between the causes of obstruction in making the diagnosis cannot be too strongly urged. Upon the recognition of the condition will depend the advisability of instituting surgical interference. The essential points to observe in making a differential diagnosis of the various obstructive conditions found in the common duct are,—if there has been previous attacks of bilious colic associated with tenderness in the region of the liver, with or without jaundice; if there has been vomiting coincident with the colic, or prior to it; if the initial colic had been followed by an attack of jaundice occurring shortly after the onset of pain; if there has been vomiting coincident with colic, or prior to it; if the patient has suffered with recurrent attacks of colic and jaundice with an irregular fever occurring some time after the paroxysmal seizures. To differentiate between stenosis and other nonmalignant obstructions of the duct without an exploratory laparotomy would be an absolute impossibility.

The most common malignant condition resulting in obstruction of the duct is cancer of the head of the pancreas. The symptoms in malignant disease of the pancreas are marked by progressive loss of weight and strength, digestive disturbances, pain, the absence of characteristic colic, without disturbance of the temperature, and the presence of a tumor in the epigastric region.

The treatment of obstruction of the common bile-duct is divided into two classes, the medical and the surgical; the medical treatment is subdivided into the expectant and the preventive. The surgical treatment offers the most positive means of removing the obstruction, providing it is not of malignant origin.

The best that can be expected from medical treatment is that the symptoms may be allowed to subside, and the jaundice, if present, disappear, so as to afford the surgeon the most favorable opportunity to remove the cause of the obstruction.

The dangers in delaying operation are many; infection, ulceration or perforation of the duct, cholecystitis or cholangitis, localized peritonitis, rupture of the duct with a subsequent general peritonitis, or if walled off by adhesion, subdiaphragmatic abscess, pyelophlebitis, abscess of the liver, and thrombosis of the portal vein.

The treatment for obstruction of the common duct other than surgical is directed first to control pain by the administrations of opiates, the application of hot poultices to the right hypochondrium, prolonged hot baths, stimulants to control the shock and the administration of alkalines, and alkaline mineral waters.

There are certain cases in which an operation would be attended by a fatal outcome, the chief causes being old age, shock, and extreme jaundice which has been present for a long period. In the latter instance, the danger arises from the liability to uncontrollable fatal hemorrhage consequent to the jaundice.

The incision to expose the common duct is a vertical one, carried through the right rectus muscle; in making the incision include the rectus muscle it affords a better safeguard against ventral hernia than does that going through the semilunar line.

In no intraabdominal operation is it more important to thoroughly wall off the field of operation than in opening the common duct. The gauze is so arranged that it will keep the site of the operation free from loose coils of bowels or omentum, thus affording an opportunity to thoroughly expose the field of vision uninterruptedly, and permit the necessary freedom for manipulation. After thoroughly walling off, the gallbladder is inspected, and if found to contain stones, is emptied: the finger is then introduced into the foramen of Winslow, and brought directly in contact with the common duct. If a stone is present it is usually found occupying the duodenal end of the duct. The duct is incised and the stone extracted; a rubber drainage tube is introduced into the duct, around which sterile gauze is packed, the walling-off gauze is removed, and if the gallbladder has not been opened, the wound is closed, except at a point to permit the rubber drainage-tube and protecting gauze to protrude.

If the stone occupies the extreme lower portion of the common duct, and is fixed there, an operation devised by Dr. McBurney will offer an excellent means of delivering the stone without incising the duct in its continuity; this makes it possible to close the abdomen without the fear of subsequent leakage from the duct.

The operation devised by Dr. McBurney consists in carrying an incision through the right rectus muscle from the tip of the cartilage of the ninth rib parallel to the fibers of the muscle, 2 inches from the median line. An incision is made into the middle of the descending portion of the duodenum, the opening of the common duct exposed, and a probe is introduced into the duct to explore it. The opening of the duct is easily found, enlarged by incision and dilated, the stone grasped and extracted, the wound in the duodenum stitched and the abdominal wound closed. This certainly offers a very fair avenue for attacking a stone in the duct, and permits quite as free manipulation as does an incision into the duct.

The common duct is readily palpated with the finger introduced into the foramen of Winslow; the location, size of the stone, and possibility of removal or of incision into the duct may be determined by the examining finger. It is possible to attack the common duct by the extraperitoneal route. The second or descending portion of the duodenum is but partially covered by the peritoneum; the reflection of the post-parietal peritoneum is divided at the second portion of the duodenum to the outer side, exposing the common bile-duct and the pancreatic duct which perforates the inner side of the duodenum somewhat obliquely just below its middle portion. The common duct is opened, the stone removed, and drainage introduced or the duct sutured.

In any operation on the common duct which involves opening the duct it is safest not to trust to stitching alone, but to reinforce the line of suture with gauze packing, so that in the event of leakage from the duct or failure of the sutures to hold, the peritoneal cavity will not be infected from the escaping contents of the duct. If the gallbladder is found to be contracted at the time of operation, it is not necessary to open it unless stones are found contained therein. In a certain

percentage of cases of obstruction of the common duct, I open and drain the gallbladder, whether the latter is diseased or not.

In carcinoma of the common duct, when seen early without adhesion, or if not too much involved, resection of the duct and transplantation into the duodenum will overcome the obstruction. Where the area involved is too great to accomplish transplantation of the duct, a cholecystoenterostomy will suffice to establish the biliary circulation.

A cholecystoenterostomy is also called for when the obstruction is due to cancer of the pancreas or of the pylorus, and it may be advisable in certain cases of obstruction from stone as a preliminary to the operation upon the duct.

THE RELATION BETWEEN GALLSTONES AND APPENDICITIS.

By A. J. OCHSNER, M.D.,

of Chicago, Ill.

Surgeon-in-Chief to Augustana Hospital and St. Mary's Hospital; Professor of Clinical Surgery in the College of Physicians and Surgeons.

THAT it is frequently difficult to make a differential diagnosis between gallstones and appendicitis has been pointed out by many of the most experienced authors,—Deaver, Fowler, Mynter, Murphy, Lennander, Kehr, and others. A few surgeons,—Maurice Richardson, Sonnenburg, and Kölliker—have reported cases in which both conditions existed in the same patient, but, so far as my study of both subjects has extended, I have been unable to find any author who has considered a relation between the two conditions.

During the past few years I have operated upon a number of patients suffering from acute or chronic appendicitis, in whom I discovered, incidentally, stones in the gallbladder, and vice versa I have operated upon patients for the relief of gallstones and have found this condition complicated with chronic appendicitis. In these cases the appendix was usually extensively adherent; the cecal end was partly or wholly obliterated; the distal end was club-shaped and contained septic material in the form of fecal concretions, pus or mucus. The frequency with which these two conditions coexisted in the same patient seemed to indicate some relation between these two pathologic conditions. As a result of these observations I began on February 1, 1900, to examine the appendix in all patients upon whom I operated for the relief of gallstones, and I have arranged a table of all the gallstone patients upon whom I operated at the Augustana Hospital during the four months of February, March, April, and May of the present year. I have also added the histories of all cases in whom both gallstones and appendicitis were present. I had intended to include a longer period of time, but find that this would carry me beyond the limits of this paper. Moreover, I believe that the number of cases tabulated is sufficient to warrant my conclusions.

During these four months I operated upon 18 patients suffering from gallstones, and of these 6, or one-third of the entire number, suffered at the same time from appendicitis. In each one the extensive adhesions, or the cicatricial contractions, showed that the patient must have suffered from a violent, acute attack of appendicitis at some time, and in each case the appendix contained septic material in the form of fecal concre-

tions or pus. It seems clear, then, that during the acute attack an infection of the gallbladder with the colon-bacillus could have been easily accomplished, and this also would have been possible during the long-continued chronic appendicitis following.

Cushing and others have pointed out the fact that a considerable proportion of all patients suffering from gallstones have previously had typhoid fever. Mignot and others have shown experimentally that the colon-bacillus is capable of causing the formation of gallstones. Gilbert and Fournier seem to have proved beyond a doubt that microorganisms actually are the exciting cause in the formation of gallstones.

These facts are borne out by many other observers, both in the field of experimental and clinical surgery, so that there can scarcely be any doubt concerning the correctness of the theory that infection is the essential cause in the formation of gallstones, although there are undoubtedly many predisposing causes, such as faulty diet, constipation, tight lacing, sedentary habits, etc. It is plain that infection can readily occur either through the lymphatics or through the venous system; or, during the acute attack of appendicitis, when the entire alimentary tract, above the ileocecal valve, is filled with infectious material, infection through the common duct is quite possible.

The experiments of Nasse have shown that the contents of the gallbladder become septic upon closure of the common duct; direct infection is not at all necessary.

With one exception, all of these patients suffered from the acute attack of appendicitis at a time when a diagnosis of this disease was rarely made, hence the histories fail to bring out the fact that the patient has suffered from appendicitis, notwithstanding the pathologic conditions found at the time of operation demonstrate this fact beyond a doubt. It is to be expected that in the future this will be different because at the present time all competent physicians recognize this disease. I will say that in but one of these cases a positive diagnosis of gallstones complicated with appendicitis was made, although I have come to suspect the presence of chronic appendicitis in cases suffering from gallstones, and, consequently, always make a possible diagnosis of the former condition.

During the four months covered by these cases I operated in all upon 61 patients suffering from appendicitis, counting the 6 in whom this condition was incidentally found in connection with gallstones, so that apparently, according to this series of cases, 33% of all gallstone cases had appendicitis and only 10% of all appendicitis cases had gallstones. It should be borne in mind, however, that the latter proportion may not be correct, because it seemed unwise in many cases operated upon for acute appendicitis to examine the gallbladder, while the appendix was examined in all cases operated upon primarily for the relief of gallstones.

From a clinical standpoint these observations are undoubtedly of value, because they show the importance of examining the appendix when operating for the relief of gallstones. Of these 18 cases 6 would undoubtedly have continued to suffer after the gallstones were removed, had not the diseased appendix been excised. If a vertical incision is made through the edge of the right rectus abdominis muscle, the cecum and appendix can be brought up for inspection, and in case of extensive adhesions this incision can safely be extended downwards sufficiently to make the removal of the diseased appendix possible.

On the other hand, in case one suspects the complication of appendicitis with gallstones, one can readily remove the diseased appendix through an incision made through the right rectus abdominis muscle in a position opposite McBurney's point, and from this incision one can readily examine the gallbladder.

CASE No. 7372.—A married woman, 63 years of age, came under my care March 18, 1900.

History.—Her family history was negative. She had sustained the ordinary diseases of childhood. Menstruation appeared at the age of 18 and was always regular and painless. She was married at the age of 25; had 7 normal labors and one miscarriage at three months. The menopause appeared at the age of 40. During the past 23 years she has had repeated attacks of pain in the epigastrium, usually accompanied by vomiting, lasting from 2 to 14 days, and occurring from 1 to 6 times a year. She was never jaundiced. Nine weeks ago she had a severe attack of pain in the right hypochondrium, accompanied by vomiting and chills. The pain was excruciating for about two hours, and the patient remained in bed for about one week. The urine was very dark in color; the stools were not observed. She has had three similar attacks since. Three weeks ago she had an attack accompanied by jaundice and lasting about a week. The last attack began one week ago and has been continuous.

Present Condition.—The patient is fairly well-nourished but considerably under her usual weight; tongue is clean and dry; complexion good; appetite fair; bowels move regularly, except during attack, when she is constipated; temperature normal, pulse regular; arteries tortuous and walls firm; heart, lungs, and kidneys normal; abdomen somewhat distended; considerable tenderness is felt in both hypochondriac regions upon pressure; entire abdomen is somewhat tender; there are no friction-sounds over gallbladder, and no abnormal dullness in abdomen.

Diagnosis.—Gallstones.

Operation.—An incision was made through the edge of the right rectus abdominis muscle, reaching from a point even with the umbilicus 3 inches upwards. It was necessary to lengthen this incision slightly in a downward direction in order to bring up the cecum and appendix. There was a strong adhesion $\frac{3}{4}$ of an inch wide from the cecal end of the appendix, extending from the appendix to the peritoneal covering of the iliacus muscle, making a short bend of the appendix. The end of the appendix was club-shaped and contained gas, which could not be expelled by pressure. The appendix contained soft fecal matter. The appendix was removed and the stump buried in the cecum.

The gallbladder was as large as a hen's egg and contained 35 strongly faceted stones varying from $\frac{1}{8}$ to $\frac{1}{2}$ inch in diameter. They had evidently been exposed to friction for a long time. One stone, $\frac{1}{2}$ inch in diameter, was in the common duct. By inserting small dressing forceps and dilating the biliary duct, pressing the common duct between finger and thumb, it was possible to shove the stone back into the gallbladder and remove it. The gallbladder was attached to the peritoneum and drained. The patient made a normal recovery, leaving the hospital 5½ weeks from the date of operation.

CASE No. 7386.—This patient came under my care at the Angustana Hospital, March 20, 1900, and is a married woman of 34 with a good family history.

History.—Was always well as a child. Menstruation commenced at the age of 15 and was regular and painless. She was married at the age of 22; had one pregnancy at the age of 24, but miscarried at 5½ months. Her health was impaired for 6 months following this experience. Eight years ago she began to be troubled with slight attacks of colicky pain in the region of the epigastrium. These pains continued for about one half hour and were frequently repeated during the period following, at intervals of from one week to a month. These attacks were supposed to be due to gastric disturbances. She was then well for a year and a half when the attacks returned with greater severity. They have persisted ever since. When the patient has been confined to liquid diet she has felt fairly well, but on attempting to eat solids she has invariably suffered. During all this time she has been under treatment for gastric disturbances.

One year ago she examined her stools after one of her attacks and found several gallstones. Since this time she has taken olive oil at intervals and has always felt better for it. During the past six months she has noticed some pain in the right inguinal region. Previously, her pain had always been confined to the region of the epigastrium.

Present Condition.—The patient is obese; pulse and temperature are normal; tongue somewhat coated; appetite fair; bowels regular while she takes olive oil; heart, lungs and kidneys are normal. The abdominal walls are exceedingly thick and there is a considerable amount of tenderness, especially in the right inguinal region.

Diagnosis.—Gallstones, complicated with appendicitis.

Operation.—An incision, 6 inches in length, was made in the right linea semilunaris. The layer of fat being unusu-

bladder was universally adherent to the liver, the stomach and the omentum. Its walls were much thickened and it was impossible to bring its lower end up to the parietal peritoneum. The upper end was sutured to the parietal peritoneum; to the lower end a piece of iodoform gauze was sutured with catgut, and this was passed out through the upper angle of the wound. The gallbladder was drained and the abdominal walls closed up to the point of drainage. The gallbladder besides the stones contained a quantity of mucus which was evidently septic. As a result of this a marked suppuration of the wound occurred, and the patient was not able to leave the hospital until nine weeks after the time of the operation. But she recovered fully.

CASE No. 7414 came under my care at the Augustana Hospital on the 26th of March, 1900. The patient is a

NOTE.—The large number opposite each name corresponds with the number in the Hospital records, and is used for purposes of identification.

ally thick the incision, down to the fascia, was extended above and below for a distance of 4 inches, making the entire incision through the fat 14 inches, in order to make it possible to manipulate the intraabdominal structures. The appendix was surrounded by a mass of omentum which extended below and behind the cecum; it was found universally adherent. In order to facilitate its removal two hemostatic forceps were applied to it, one at its junction with the cecum, the other $\frac{1}{4}$ inch beyond this point. It was then severed between these two forceps; the omentum and adhesions were then ligated and the appendix removed with the mass of omentum surrounding it. Its cecal end was almost completely obliterated, and it contained four fecal concretions the size of a lemon seed, and a small quantity of pus and mucus.

The gallbladder was the size of a hen's egg and contained 36 gallstones varying in size from that of a filbert to that of a pea. The stones were all strongly faceted. The gall-

married woman, 36 years of age, and gives the following history:

History.—Her family history is good. She had always been in good health, with the exception of having suffered from typhoid fever ten years ago. She had suffered for many years from a feeling of soreness in the right hypochondrium, and during her convalescence from typhoid fever she had severe colicky pains in the region of the gallbladder. During the following year she had repeated attacks at short intervals. These became less frequent, but more severe. Six years ago she gave birth to a child normally. After this she was free from the attacks for two years; then she had sudden attacks almost daily for a year, when she became pregnant again, remaining free from attacks until the birth of her child, since which time the attacks have been nearly constant. She has never been severely jaundiced, but the sclera has been slightly yellow. Occasionally minute gallstones have been found in the feces. The pain has been so severe that

the patient has acquired the morphia habit, taking as high as 2 grains, in divided doses, during one hour, but rarely taking more than 6 grains during the 24 hours.

Present Condition.—Patient is well nourished; pulse and temperature normal; tongue clean; appetite good; bowels regular; heart, lungs, and kidneys normal. Slight tenderness under right costal arch; liver is not perceptibly enlarged; tenderness in right inguinal region.

Diagnosis.—Gallstones.

Operation.—An incision 3 inches long was made through right rectus abdominis muscle, from a point opposite the umbilicus upwards. The cecum and appendix are brought into the wound; the latter is 4 inches long, and has an exceedingly thick mesentery, extending beyond the distal end. The appendix contains 4 fecal concretions which cannot be forced into the cecum through a contracted cecal end. The appendix was removed and the stump inverted into the cecum. The gallbladder was found universally adherent to the liver, the omentum and the transverse colon. It was shrunken to the size of a walnut, and could be located only with difficulty after separating some of the adhesions. It contained 2 small cubical gallstones the size of a kernel of corn; a third one of the same size and form was found tightly wedged into the biliary duct, and could be removed only after being crushed by means of a small curet, which was inserted along its border.

A gauze drain was attached to the gallbladder by means of catgut stitches, the gallbladder tamponed with iodoform gauze and a glass drainage tube passed down through the abdominal wound to a point behind the gallbladder. The remaining portion of the abdominal wound was closed by means of stitches.

The patient made a normal recovery, leaving the hospital in a little less than 5 weeks from the time of the operation.

CASE No. 7501.—A married woman, 34 years of age, came under my care April 17, 1900.

History.—Her mother died at the age of 62, of tuberculosis of the lungs; one sister died of the same disease at the age of 47; otherwise family history is good. She suffered from children's diseases; menstruation began at the age of 14 and has always been regular and painful; was married at the age of 25 and has experienced two normal pregnancies. During the past two years menstruation has been slightly irregular, being from two to five days late. Two years ago she noticed a swelling in the right hypochondriac region which has become more and more prominent; four months ago this became tender; the size of this mass has changed from day to day. The patient has never been jaundiced, but the color of her skin is not clear; she has never had biliary colic.

Present Condition.—Patient is well nourished; tongue slightly coated; appetite fair; at times has feeling of pressure in epigastrium and eructations of gas; bowels regular; pulse and temperature normal; heart, lungs, and kidneys normal. There is a slight enlargement of the left, and considerable enlargement of right lobe of thyroid.

Abdominal.—The abdomen is slightly resistant and there is tenderness in the right inguinal region. Under the right costal arch a smooth mass can be felt and palpated between two examining hands; it moves downward upon deep inspiration and can be held down after expiration.

Diagnosis.—Cyst of gallbladder.

Operation.—An incision 6 inches long was made through the right rectus abdominis muscle, with its middle portion opposite the umbilicus. The cecum was brought up into the wound exposing an appendix 3½ inches in length, constricted at the cecal end and containing a fecal concretion the size of a date stone; the appendix was removed.

The gallbladder formed a cyst the size of a large fist, containing clear viscid fluid; it also contained 3 gallstones, conical in shape and ¾ inch in diameter; one of these stones was tightly wedged into the neck of the gallbladder with its sharp end projecting into the biliary duct; it required a considerable amount of force to press this stone back into the gallbladder; the gallbladder was tamponed and drained and attached to the parietal peritoneum, and the abdominal wound was closed up to this point.

The patient made a perfect recovery, leaving the hospital 5½ weeks from the time of the operation.

CASE No. 7529.—This patient, a married woman 42 years of age, came under my care April 24, 1900.

History.—Family history good. She was well as a child; menstruation began at the age of 15; was regular and painless; the menopause occurred at the age of 41. She was married at 27 and had one normal pregnancy. Until one year ago her health was good with the exception of suffering from sick-headache accompanied by vomiting bile, but this has become less frequent during the last few years. During the past year she has had occasional slight pains in the abdomen, especially under the right costal arch; considerable eructation of gas; bowels have been constipated.

Present Condition.—Patient is fairly well nourished, but weighs 30 pounds less than a year ago; complexion is fair; tongue clean; appetite good; three or four hours after eating she has an empty, gnawing feeling in the epigastrium, from which she also suffers in the morning, and at these times she often vomits bile which relieves her distress; temperature 99°, pulse 84; no jaundice; heart, lungs and kidneys normal; abdomen slightly scaphoid; appendix palpable at McBurney's point; slightly enlarged. There is some gurgling in the abdomen, and almost directly under the right costal arch there is a smooth, somewhat movable mass which passes down with deep inspiration so that the lower pole is below the umbilicus; it can be held there after the liver recedes.

Diagnosis.—Chronic appendicitis; cholecystitis; floating kidney.

Operation.—Incision made through right rectus abdominis muscle, at its upper third, 3½ inches in length. The cecum and appendix were brought into the wound, the latter being 4½ inches long and containing an enterolith ½ inch in its smaller and ¾ inch in its greater diameter.

There is a constriction about the middle of the appendix, due to the twist caused by the adhesions formed by a portion of the appendix opposite the mesentery to the peritoneal covering of the iliacus muscle. The mesentery is very narrow, but extends to the end of the appendix; the appendix was excised.

The gallbladder was strongly adherent to the omentum, and distended to the size of a hen's egg; no biliary calculi felt within it. The contents of the gallbladder were aspirated, consisting of a viscid fluid containing fine, black sand; it was sutured to the parietal peritoneum, tamponed, and drained, and the abdominal wound closed up to this point.

Nephrorrhaphy was performed for relief of the floating kidney. The patient recovered, leaving the hospital 4½ weeks from date of the operation.

CASE No. 7553.—A married man, 48 years of age, who came under my care at the Augustana Hospital, April 29, 1900, giving the following history:

History.—He had always been in fairly good health until about 12 years ago, when he began to suffer from what was supposed to be gastric disturbance. At this time he suffered from acute indigestion, his attacks coming on suddenly and being accompanied by severe pain and nausea. He received internal treatment at intervals during this time, but was never entirely free from the sense of discomfort. Two years ago these attacks became so frequent that he was practically unable to work at his trade in the wire mills. The patient has never been distinctly jaundiced, but the color of his skin has not been clear for a number of years.

One year ago the patient consulted me and I then made a diagnosis of gallstones and advised an operation. This was refused and the patient returned to his home and continued the internal treatment until the date of his admission to the hospital.

Present Condition.—The patient is well nourished; tongue coated; appetite fair; constantly suffers from feeling of fullness in region of stomach; bowels constipated; pulse and temperature normal; heart, lungs, and kidneys normal. There is a slight enlargement of the liver, and a tenderness in the region of the gallbladder upon deep pressure. The skin has a slight yellowish tinge, but there is no jaundice present.

Diagnosis.—Gallstones in gallbladder. Appendicitis.

Operation.—An incision was made through the edge of the right rectus abdominis muscle at a point 1 inch below the umbilicus, for a distance of 4 inches in an upward direction. The cecum and appendix were brought up into the wound. The appendix was constricted at the cecal end so that a fine probe could scarcely be passed through its lumen. The distal end was enlarged to the size of a little finger, and con-

tained a hard fecal concretion. The whole appendix was attached to the lower end of the cecum and had the outlines of an interrogation point. The appendix was removed.

The gallbladder was contracted closely down upon a number of gallstones. No note was made of the exact number, but there were at least one dozen stones, varying from the size of a pea to that of a filbert. All of these stones were strongly faceted, showing that they had remained in the gallbladder for a considerable length of time.

The patient left the hospital on the 14th of June, 6 weeks from the date of entrance.

THE ETIOLOGY OF GALLSTONES.

By FREDERICK C. SHATTUCK, M.D.,

of Boston, Mass.

Our knowledge of this subject leaves much to be desired. The presence of gallstones can often be diagnosed, and the knife frequently brings about a radical cure when the stones prove troublesome. But we must know much more than we know now, before we can hope to do much to prevent gallstone-formation or to dissolve or expel them by medical, prophylactic, and remedial measures.

There is a large variation in the statistics of different observers as to the prevalence of gallstones. Poulsen finds them in 3.8%, Riedel in 18% of all cases coming to autopsy. Brockbank finds them in 7.3%, Schröder in 12.5%.

On these points we have accurate knowledge:

1. Gallstones are composed mainly of cholesterin; often partly of bilirubin calcium precipitated by changed reaction of the bile. Bacteria of one kind or another are, to say the least, very common. A nucleus may be formed of bilirubin calcium, bacteria, a foreign body, or of a combination of these. Cholesterin is normally held in solution by the bile. Frerichs and Naunyn agree in considering stasis, catarrh, and a reaction-change of the bile as factors. They differ practically only in their explanation of cholesterin-formation. Frerichs thought it formed from the bile itself; Naunyn believes it to be derived from degenerated cells.

2. Age has a distinct influence. Gallstones are not unknown even in childhood, but are rare under 30; from 30 to 60 they are more, and, broadly speaking, about equally common for each decade; after 60 they show a marked increase in frequency. According to Thoma they are found in 25% of all persons of 60, or over, coming to autopsy.

3. They are from 2 to 4 times as common in females as in males.

Anything which causes stasis of bile is thought to predispose to gallstone-formation. With this idea, age and sex incidence are both consistent.

As age advances, physiology merges into pathology, in a sense, and retrograde processes are no more remarkable in the gallbladder and biliary, than in the urinary bladder and urinary passages, in the arterial coats, or in the organs and tissues generally. In addition to this, people become less active and are apt to put on fat as age advances.

The influence of sex may be reasonably explained by the more sedentary lives led by females, and also by their dress, which too often impedes respiratory and general motility and, with the addition of pregnancy and relaxed abdominal wall, would seem to partly account for the formation of gallstones in women, just as it does for floating kidney, gastropexia, and the like.

Gallstones are said to be more common in the insane than in the mentally sound, perhaps as a result of diminished bodily activity.

More interesting is Brockbank's statement that they are unduly common in the subjects of chronic heart-disease, especially of mitral stenosis. Here again comes an inactive life in addition to a tendency to chronic passive congestion. The well-known incidence of mitral stenosis to the female sex is also noteworthy.

Let us now consider catarrh and its mode of origin.

Modern bacteriology throws much light on this question. For the sake of brevity I will formulate the conclusions which seem to be justified by a careful study of the literature of the subject to date, making no references and mentioning few names.

1. A sterile foreign body does not lead to gallstone-formation, though a sterilized gallstone may be penetrated by, at least, the colon-bacillus.

2. The contents of the hepatic and cystic ducts, and also of the gallbladder are usually sterile.

3. The common duct not infrequently contains bacteria, a fact readily explicable by the relation of the duct to the intestines.

4. Gallstones have been produced experimentally by a number of observers, with a number of organisms. Mignot failed with virulent cultures, while he succeeded with attenuated cultures, alone, or in connection with a foreign body.

5. The presence of bacteria has been demonstrated in connection with a considerable proportion of cases of gallstones.

6. The clumping of the typhoid-bacillus led Dr. M. W. Richardson to think this peculiarity might play an important role, and he produced gallstones in a rabbit by the introduction of a small amount of a clumped bouillon-culture into the gallbladder.

7. The colon-bacillus and the typhoid bacillus are the most common bacterial agents in gallstone formation.

Thus it would seem that stasis of the bile is a very important factor. This once established permits a change in the reaction of the bile contained in the gallbladder, favors precipitation of bilirubin calcium, increases cell-desquamation from the gallbladder-wall, and affords a nidus for the growth of bacteria, possibly derived from the blood, probably usually from the common duct and intestines. The broad therapeutic deductions are, hence, to forestall in all ways in our power causes of stasis, and to annihilate typhoid fever. The combat is with fashion and with disease, and the former is less hopeful.

INDICATIONS FOR THE DRAINAGE IN DISEASES OF THE BILIARY PASSAGES AND THE TECHNIC OF OPERATION.

By J. E. SUMMERS, JR., M.D.,

of Omaha, Neb.

Surgeon-in-Chief to Clarkson Hospital; Attending Surgeon Douglas County Hospital.

AFTER any operation upon the gallbladder or gall-ducts temporary drainage is required. The drainage may be either *direct* from wounds made into the gallbladder or gall-ducts, or *indirect* from the area of the operation field after suture of such wounds. Whether the drainage will be direct or indirect depends upon the indication for

which an operation is performed. The rule is that drainage should be direct.

The chief indications for operating in affections of the gallbladder or bile-ducts being the same as those for drainage may be briefly summarized as follows:

1. In acute or chronic inflammations of the gallbladder or ducts which are not amenable to medical treatment and which occur independently or as complications or sequels of infectious diseases.

2. In gallstones in the bladder or ducts producing frequent attacks of biliary colic with or without mild jaundice.

3. In palpable enlargement of the gallbladder, especially if the constitutional and local symptoms point towards the presence of pus.

4. Whenever the history combined with the local and constitutional symptoms indicate phlegmonous or ulcerative cystitis, and more urgently still if commencing gangrene of the gallbladder is suspected.

5. In puncture, perforation or rupture of the gallbladder.

6. In suppurative inflammation of the ducts of the liver.

7. In all cases symptomatically pointing towards connective tissue (stricture) or gallstone obstruction in the gall-ducts.

8. Whenever inflammatory adhesions or new growths interfere with the normal outflow of bile into the duodenum.

9. In addition it might be mentioned that as sometimes it is impracticable to drain infected or obstructed bile-ducts externally, methods are available by which continuous drainage may be established into the intestinal tract.

The technic of cholecystostomy varies according to the object for which the operation is performed and the condition of the gallbladder walls. Any one of the several incisions through the abdominal wall may be employed. Whichever one is selected must be of sufficient length to allow the introduction of the hand in order to permit careful palpation of the bile-ducts.

If an oblique incision is selected it will often be found that the peritoneum on the outer upper side tends to be drawn away from the incision. In closing the peritoneum some annoyance is occasioned by this retraction. This is easily overcome if the operator will take the trouble to introduce two "guy rope" sutures through the peritoneum; one at the lower angle, and the other on the right side of the incision at about the point where it is expected to fasten the lower part of the gallbladder fundus. Two pair of short tenaculum "bullet" forceps are useful and time-saving for this purpose—one point is introduced through the peritoneum and the other into the edge of the skin incision or aponeurosis and then the blades are clamped. These forceps are very useful in the "gridiron" or muscle-splitting operation for recurrent appendicitis. They are in such a case fastened opposite one another, drawing the peritoneum towards the surface, thus allowing easier and safer manipulations of the operator's fingers.

It is generally wise to aspirate the gallbladder, especially if its contents are septic, *before* sewing it to the parietal peritoneum or incising its walls. By doing so the danger of contaminating the peritoneum is lessened, likewise the technic of cholecystostomy simplified. If the gallbladder is distended the ability of the operator to palpate the bile-ducts is much facilitated by a preliminary aspiration.

When the object of drainage is temporary and the gallbladder walls not much thickened, a special technic is essential to the early closing of the opening. The cut edge of the gallbladder should project little if any above the peritoneum and the mucous membrane should be inverted in order that the opening into the gallbladder, through which the drain passes, shall be lined by peritoneum. When the opening into the gallbladder is arranged in this fashion there is no delay in adhesion with closure of the lips of the cyst after the withdrawal of the drainage-tube. In doing the operation of cystostomy for temporary drainage the writer has for some years followed a technic which is simple but ideal in carrying out the suggestions just made. A practically identical method was published several years ago by a former Nebraska physician, Dr. W. D. Jones.¹ The operation is done as follows: The gallbladder is sutured in the usual way to the parietal peritoneum so that the distance between this line of suture and the edge of the

FIG. 1.—Diagram illustrating method of introducing sutures to invert edge of gallbladder.

incision into the cyst is about 1 cm. to 1.5 cm. In order to invert the edge of the gallbladder wound, mattress stitches of chromic catgut are introduced at suitable intervals. Enter the needle near the lips of the abdominal incision so that it will pass in a circular fashion through the muscle and aponeurosis, or the aponeurosis alone, emerging just above the peritoneum, near the line of suture to the gallbladder. The needle then pierces the cyst-wall (all coats) just within the line of suture and is brought out again close to the edge of the incision into the gallbladder. It is then reintroduced near this wound edge and brought out again at a point on a line with the first point of entrance. The aponeurosis and muscle are then pierced in a direction parallel to the line of entrance from within and the needle brought out near its original point of entry. The distance between the basic and edge punctures being about $\frac{3}{4}$ the

¹ Dr. Jones is entitled to much credit for his experiments upon dogs. His work has improved former methods of inverting the edge of the gallbladder in cholecystostomy.

distance between the peritoneal line of suture to the gallbladder and the edge of the incision into the gallbladder. A sufficient number of these sutures are introduced together with single sutures through the same structures across the upper and lower angles of the wound. When all these stitches are tied a button-hole opening is formed, having a round peritoneal edge. In

FIG. 2.—Section showing inversion of gallbladder-edge after tying sutures.

absence of pronounced cholemia this method ought to be varied by removing a strip of mucous membrane from the edge of the gallbladder-wound. The width of this strip should be slightly less than the distance from the cut edge of the gallbladder to what is to be the basic line of inverting stitches. This technic controls bleeding from the trimmed edge of the mucous membrane and admits of adhesions of the inverted flap; it prevents any possible pouting of the gallbladder incision, which might occur if the wound were a long one and the drainage-tube too small to make sufficient pressure against the inverted edge until firm adhesion of the peritoneal surfaces at the angles had taken place.

Whether the drainage is kept up a few days or as many weeks, the opening into the gallbladder will close with the withdrawing of the drainage tube. If a little pressure is applied to the sides of the abdominal wall on either side of the incision, the peritoneal surfaces of the inverted gallbladder would adhere almost immediately; little or no bile will discolor the dressings after 24 hours. Of course, one must know that the ducts are clear for the natural discharge of bile into the bowel before any attempt at closure of the external drainage. A more or less rapidly-forming tumor in the area under and below the closing wound will indicate obstruction and necessitate a reopening of the gallbladder. Whenever it is intended that a permanent fistula be formed the mucous membrane of the gallbladder must be everted by sewing the edge of the gallbladder-wound to the skin. Before putting in these stitches it is safer to sew the parietal peritoneum to the gallbladder. The distance between these rows of suture should be such as not to put too great strain upon the outer row and thus invite sloughing of the edges of the gallbladder. This should also be the method of fixation whenever it is intended to do any operative work on the cystic duct through the gallbladder, because such fixation brings the area of attack nearer the surface, besides it affords better protection to the peritoneal cavity.

In order to close an opening into the gallbladder when the mucous membrane is everted and reaches towards the skin-edge the plan we have followed with greatest satisfaction is to free the projecting neck of gallbladder and then after loosening the peritoneum, in the area of the wound, from its superlying structures, the edge of the gallbladder is inverted and closed by means of catgut stitches. This operation is entirely extraperitoneal. Sometimes we have carried the work a step further by breaking up the adhesions of the gallbladder to the cut edge of the peritoneum, introducing a small drain to the gallbladder and then closing the peritoneum with the muscle and skin, leaving a small opening for the drain.

If the gallbladder is contracted or displaced far under the edge of the liver, especially if the abdominal wall is very thick, it may be impracticable to carry out the technic just given. Under such circumstances two lines of practice are available, each having special indications. One method of draining these deep-lying gallbladders is to free the peritoneum of the abdominal incision from its superlying structures so as to form a circular flap of peritoneum. This flap is then depressed to reach the gallbladder and is sewed to it with chromic catgut or silk. If silk is used each stitch must be anchored by a piece of silver wire so that the silk can be removed by traction on the wire or by cutting the stitch and withdrawing it by means of its anchoring wire. Mechanical devices such as the button and tube of Murphy may be successfully used but have no practical advantage.

If the operator is certain that there is no obstruction in the bile-ducts the simplest and easiest practice is to arrange the omentum, using possibly a few catgut stitches, to form the floor of the route from the base of the gallbladder to the lower angle of the abdominal incision. A temporary gauze pad is placed so as to catch the contents of the gallbladder which escape the sponges when it is incised. If it is evident that drainage will be required for only a very short time a drainage tube is introduced into the gallbladder and snugly tacked to the edge of the cyst by a few catgut stitches. If the drainage is to be of somewhat long duration and it is necessary to form a well isolated route for that purpose, it will be wise to employ silk to hold the tube in place, taking care to secure a sound fastening through the tube wall, in order to prevent the falling of stitches into the gallbladder to be the nuclei of future gallstones. Another aid in this direction is to pass the silk stitches through the muscular and peritoneal coats *only*, of the cyst as tending towards a lessening of the danger of a knot falling into the bladder should a stitch cut out of the drainage-tube.

The drainage-tube must be reinforced by the arrangement of from four to six thicknesses of sterile gauze in place of the provisional gauze pad, the lower end of this gauze-drain is brought out of the incision. The gauze forms a bed for the tube to lie on. In 72 hours sufficient adhesions will have formed to shut off the drainage route from the peritoneal cavity and the gauze can be safely withdrawn. If silk has been employed and it is desired to remove the tube before the stitches have cut out by pressure necrosis, traction of the tube will bring away all the stitches if they have been introduced as described. Such wounds heal rapidly without the formation of fistulas, provided there is no obstruction in the ducts.

An abscess of the gallbladder, whether due to the

irritation of gallstones or occurring during the course of an infectious disease (typhoid), requires an immediate cholecystostomy. In such cases it will be safer to fasten the gallbladder to the skin. If perforation has occurred *after* the formation of protective adhesions the case must be treated upon the same general principles applicable to any other circumscribed peritoneal abscess. If any doubt exists as to the safety of the anterior drainage we must not lose sight of the value of dependent drainage, so easily obtained by a counter opening in the right flank and the introduction from behind of tubular and gauze drains.

Out of 7 cases of empyema which I have operated upon, perforation has occurred in 4. Only 1 case died and this death, a perforation with frail limiting adhesions, was probably the result of carelessness in not providing for dependent drainage through a posterior opening in the right loin. In 2 cases perforation had occurred into the liver. They were opened by incisions through liver-tissue. One case took a not uncommon route and pointed at the umbilicus.

In gangrene of the gallbladder the offending organ must be removed. A separate ligature to the artery accompanying the cystic duct should be added to the one surrounding the duct. Neglect of this precaution has been known to result in fatal hemorrhage. Posterior dependent drainage in addition to direct anterior drainage ought to be arranged. In absence of infection within the common or cystic ducts after incision of these ducts for the removal of stones, practically an identical technic should be employed as in cholecystostomy when it is impossible to sew the gallbladder to the parietal incision. The drainage-tube is not introduced into the ducts, but its end is fastened opposite the opening into the duct by means of one or two readily absorbable catgut stitches. These sutures hold the drain in place long enough for it to fulfil its purpose. It is usually unnecessary, and often inadvisable, to suture the incision in a bile-duct, as the opening closes within a few days. If it does not, then the operator has not removed all of the cause of obstruction for which the operation was done, and the drain is a guide and a protection. The writer has extracted a large stone from the common duct, sutured the duct and closed the abdominal wound *without* drainage, but this is bad surgery. Whether or not the wounded duct is sutured, the area of such a wound ought to have the benefit of temporary drainage to protect the patient against some mistake upon the part of the operator. I have at the present time two patients in the Clarkson Hospital; from one a stone was removed from the common duct; no stitches were placed in the duct; tubular and gauze drainage was provided. From the other a stone was taken out of the cystic duct through an incision which was carefully sewed up; tubular and gauze drainage was again provided. Both patients are making smooth recoveries, the common duct case doing a little the better. When the gall-ducts are infected and it is impossible to establish satisfactory drainage through the gallbladder by means of a cholecystostomy the cystic or common duct, one or both, should be incised and tubular and gauze drainage provided. The tube should enter the lumen of the duct and be sewed in place with chromic catgut. In such cases lateral dependent drainage through the pouch of peritoneum in front of the right kidney is a wise precaution against peritonitis.

Whenever an irremovable obstruction exists in the lower end of the common duct, complicated by a very

contracted gallbladder, both the cystic duct (when free) and the common duct become markedly dilated, likewise does the hepatic duct. It is a well-recognized fact that experience to date has shown that protracted external drainage through an incision into the common duct has a high mortality, therefore any means by which this external unnatural drainage can be converted into an internal natural drainage, is valuable. Several foreign cases have been reported in which the bile-ducts have been anastomosed to the intestine, but the writer believes that his own case (already reported) is the only one in this country. The technic is so important that it may be well to briefly describe it:

There was an impermeable stricture of the lower end of the common duct complicated by the same kind of a stricture in the cystic duct. It was found after the introduction of the respective halves of a Murphy button into the common duct and duodenum, that the only method by which the two halves of the button could be pushed home was by passing the left index finger into the foramen of Winslow so as to get its palmar surface behind the common duct and push upon the end of the half of the button introduced into this duct. The thumb and middle finger of the same hand were opposite one another and grasped the circumference of this half of the button through the duct walls. With this half of the button thus supported the anastomosis was readily accomplished by the usual manipulations. Possibly if an anastomosis were attempted between the cystic duct and the duodenum the procedure could be carried out quite as readily as when the gallbladder is joined to the bowel, but when necessity compels the operator to select the common duct the manipulations just outlined are practical and ideal.

Whenever adhesions are found around the area of a gallbladder or bile-duct operation field, they should be broken up and any mechanical interference with the function of the parts involved, corrected. But if adhesions serve a useful purpose against infection, either at the time of operation or subsequently, great care should be taken not to disturb them. Incised, punctured, and gunshot wounds of the bladder and bile-ducts demand the same surgical care as other intraabdominal traumas with the exception that sutures may be dispensed with in injuries of the bile-ducts and the same drainage-technic employed as when the injury is inflicted by the surgeon.

A CASE OF GALLSTONE OBSTRUCTION OF THE CYSTIC DUCT, ILLUSTRATING THE DIFFERENCE IN PATHOLOGY, SYMPTOMS, AND TREATMENT BETWEEN THIS AND GALLSTONE OBSTRUCTION OF THE COMMON DUCT.¹

By FREDERICK A. MCGREW, A.B., M.D.,

of Davis, Ill.

THE following case of dropsy of the gallbladder presents that interesting condition so typically as to be worth relating. It will also serve to illustrate the difference between gallstone obstruction of the cystic duct and gallstone obstruction of the common duct,—a difference which extends to the pathology, symptoms, and treatment.

Mrs. —, 36 years of age, is a farmer's wife, very industrious, and the mother of five robust children. My first

¹ Read before the Stephenson County Society of Physicians and Surgeons, April 12, 1901.

visit to her was in June, 1899, five months before the attack which led to operation. At that time she was vomiting, and complained of pain in the umbilical region and epigastrium. Her pain and vomiting were so easily and promptly relieved by chlorodyne that I attached little importance to the attack, and considered it to be what she herself had called it, "a bilious attack."

November 21, I was again called to see her, and found her sitting up, complaining of pain in the abdomen as before, and vomiting. On account of the pain she maintained a stooping or bent posture when sitting or walking, getting some relief from her pain in that position. On inquiry I found that she had never been free from soreness and dragging pain in the right side and epigastrium since the previous attack, and that she had continued to experience, during the interval, repeated slight attacks similar to the one in which I now saw her, but not of sufficient severity to demand medical relief.

She gave a history of similar attacks extended over a period of fifteen years, occurring at irregular intervals of a few to several months, all more or less painful, but apparently increasing in severity. She had never experienced pain in the right shoulder in connection with the pain of an attack, nor did it radiate in that direction. She had never been jaundiced. Her bowels had maintained a constant regularity, and the evacuations were of a normal brownish-yellow color equally before, during, and after an attack. The seat of the pain was referred by the patient to the umbilical region and epigastrium. The pain was colicky in character. Attacks came on gradually and passed away deliberately, and left her with a soreness in the epigastrium more or less quickened at times. She vomited during the severe attacks a greenish vomitus. She had never passed anything like gallstones to her knowledge.

Her tongue was coated with a grayish-white fur; her appetite moderately good; she had no headache; and was not constipated. Examination of urine taken at this time showed it to be normal. She had been losing in weight gradually and failing in strength, but more noticeably since her previous attack in June.

Examination disclosed a rounded, oblong or pear-shaped swelling, extending along the right side of the abdomen from McBurney's point upward. The lower well-rounded blunt extremity was easily defined bimanually, and was not attached. The swelling followed, upward, could be traced to the lower border of the liver, which extended two inches below the costal arch. It moved freely down and up with the respiratory movements of the diaphragm; seemed to be close to the anterior abdominal wall; did not bulge the right flank; was tender to bimanual palpation; and the fingers could not be closed together above it, nor did it slide between them as does a loose kidney.

There was no percussion-resonance above, between it and the liver. Over it the percussion-sound was one of dullness rather than flatness. Auscultation detected peculiar grating sounds which were attributed, in the greatest probability, to the grind of gallstones against one another. A diagnosis of gallstone obstruction of the cystic duct was made and operation advised. November 21, three days later, I was hurriedly summoned at night, and found the patient in a state of collapse,—pale, almost pulseless, feet cold, extremities covered with a clammy perspiration, and a numbness of the lower limbs which made the patient believe herself to be dying. She was not in more pain than usual when I saw her, but before I reached her bedside she had had very severe pain in the right hypogastrium, accompanied by a rigor of several minutes' duration. Her pulse registered 160, and mouth temperature 101°. Vomiting had occurred, but was not prominent.

She rallied slowly under the use of whisky, digitalis, and artificial heat. Operation without delay was now urged, and undertaken the following day, with the assistance of Drs. Connell and Saucerman. After the usual preparation, an incision $3\frac{1}{2}$ inches long was made along the outer border of the rectus muscle over the most prominent part of the swelling. On opening into the peritoneal cavity, the distended brownish-red gallbladder came into view, partly covered by intestinal folds. The dilated sac was packed round by sponges, aspirated, and two or three ounces of turbid, gluey mucus drawn off. There was no bile tinge to it. The last which came through the needle had a purulent appearance.

It is scarcely worth while discussing whether an empyema of the gallbladder had been secondarily implanted upon the chronic condition of retention-cyst. I am inclined to believe that the impacted stone had stirred up an acute inflammation in its neighborhood, of which the purulent matter coming from the sac at the time of operation and for three days thereafter is the supporting evidence. It is well known that an impacted gallstone is quite likely to excite an acute inflammation sooner or later. And to guard against any uncertainties the largely dilated sac was sewed to the abdominal incision and drained, as will hereafter appear.

While the sac was pushed from underneath into the abdominal wound, it was incised, and the thickness of the wall found to be from one-half to five-eighths of an inch. The wall throughout was firm, and the inner lining of the bladder was thickened, and fibrous almost to hardness. More mucus and mucopurulent matter escaped, and about seventy gallstones, half of them of large size, were removed. Most of them had crowded down into the neck of the gallbladder, and one large stone had become impacted in the cystic duct near its junction with the gallbladder. It was squeezed from its bed back into the gallbladder, and so removed, by the forefinger pressing against the duct from the outside.

The edges of the gallbladder-incision were stitched to the peritoneal margins of the upper angle of the abdominal incision. A rubber drainage-tube was pushed to the bottom of the sac, with a strip of gauze above and below. The abdominal walls were united below the drain opening. Time of operation, 20 minutes. The patient was put to bed in excellent condition. Bile began to stain the dressings almost at once, though in such quantity as indicated a patent common duct. There was no purulent discharge after the first three days. The drain tube was removed at the end of one week. The sac was irrigated once, the second day, in order to wash out any remaining gall-sand. The wound closed in three weeks, and the patient is to all appearances in perfect health at present.

The case has been detailed at some length because it beautifully illustrates the pathology, symptoms, and treatment of a condition less frequently brought to operation than obstruction of the ductus choledochus communis. So different are the two conditions that, except for their similarity of cause in impacted gallstones, they have little in common. It is this difference I wish to emphasize. Gallstone obstruction of the common duct usually has the signs of the condition so clearly evidenced that "he who runs may read." On the other hand, gallstone obstruction of the cystic duct may be beyond the diagnostic skill of the elect. And yet it may occasion long, miserable years of suffering, and relief from it come as a God-sent gift from heaven.

Gallstone impaction of the cystic duct, even if temporary, demands operative relief if the attacks recur. The classic signs of gallstones are the signs of obstruction of the common duct. Classic signs may never occur, and meanwhile our patient may be suffering from temporary, recurrent, or permanent impaction of the cystic duct. The patient whose case is herewith presented had been consulting physicians for fifteen years and had been treated for sundry and divers ailments, but gallstones had never been suggested to her as a cause of her distress. A brief comparison of the clinical and pathologic consequences of gallstone-impaction of the cystic duct and of the common duct will bring out this difference more clearly.

PATHOLOGY OF GALLSTONE OBSTRUCTION OF THE CYSTIC DUCT.

I. At the site of the obstruction a series of pathologic consequences may be entailed, beginning with sec-

ondary inflammation due to the irritating presence of the foreign body. Frequently nothing further than a mild degree of inflammation of the mucous membrane occurs, but this is doubtless constantly present. After inflammation, the possible events in the series are pressure-necrosis, ulceration, gradual invasion of the deeper tissues by the ulcerative process, perforation, abscess, inflammatory adhesions, fistula, and other sequels. Adhesions usually are formed in advance of the ulcerating process, thus preventing the disastrous results sure to follow perforation into a free serous cavity. The tissues contiguous to the inflamed territory may be successively involved until the entire mucous membrane of the ducts and gallbladder, the peritoneal covering, and the intermediate tissues become the seat of inflammation. More or less extensive adhesions may be formed binding the duct, or the gall-cyst and duct, and neighboring tissues into one mass. Suppuration may occur and the gallbladder become the seat of empyema.

II. Besides these results, there is another series which is the consequence of the pent-up secretion. The escape of the bile held in the bladder when obstruction occurs is prevented. It is gradually absorbed, so that eventually no bile taint can be discovered in the contents of the cholecyst. The mucous secretion of the gallbladder is retained, a simple retention-cyst being formed. At first stained by the bile-pigment accidentally present, gradually the contents become a translucent, turbid, thick, gluey mucus, as in the case detailed. The gall-cyst gradually is dilated by the retained secretion, and this dilation may reach remarkable proportions, even filling the right half of the abdominal cavity. The walls may be thinned as the sac dilates, or, as in the case recited, become firm, non-collapsible, and greatly thickened. Likewise the mucous lining may thin out, or on the other hand become fibrous, thick, and unyielding. Doubtless the irritating presence of gallstones and the rapidity of the dilation have an influence in determining the thickness of walls and membrane.

PATHOLOGY OF GALLSTONE OBSTRUCTION OF THE COMMON DUCT.

I. At the site of the obstruction, the pathologic possibilities are the same as in obstruction of the cystic duct.

II. Consequences of the presence of the pent-up bile: *a.* It distends the gallbladder moderately, so that it may occasionally be palpated below the edge of the liver, but the dilation never attains that extreme degree it does in cystic-duct obstruction. *b.* The gallbladder constantly contains bile. (If the hepatic duct is occluded the gallbladder will, of course, be empty of bile.) *c.* The bile-ducts dilate, even in their minutest ramifications within the liver. *d.* The liver as a whole enlarges, the parenchyma cells undergo pressure atrophy, the connective tissue increases, and cirrhosis is the final result. *e.* The pressure of the accumulated bile within the ducts becomes higher than that in the lymph-channels, the bile passes over, and is carried into the blood. *f.* The tissues throughout the body are discolored (jaundiced) greenish-yellow by the biliary coloring-matter. Externally, it appears first in the mucous membranes, and later in the skin. This pigment shows a tendency to collect more thickly in spots. *g.* The bile appears also in the urine. *h.* The presence of the bile-salts affects the nutrition of all cells un-

favorably, but more especially has a profoundly irritant effect upon the nervous elements. *i.* The bile, being partly excrementitious, contains poisonous products and toxins, which are reabsorbed, causing general toxemia.

III. Consequences of absence of bile in the intestine: *a.* Fats and oils are not assimilated, but appear in the stools, giving them a whitish, oily, glistening, pasty character. *b.* Intestinal digestion is further disturbed by reason of the want of the acid-neutralizing and antiseptic properties of the bile. *c.* The stools are very offensive and gas-formation troublesome. *d.* Constipation is the rule, due to the absence of the peristaltic stimulating qualities of the bile. *e.* Nutrition suffers and the temperature of the body falls.

SYMPTOMS OF CYSTIC DUCT AND COMMON DUCT OBSTRUCTION CONTRASTED.

Cystic Duct Syndrome.

a. Attacks of gallstone colic, exhibited by pain, rigor, vomiting, rise in temperature, symptoms of collapse,—the pain being excruciating, and referred to the right hypochondriac and umbilical or epigastric regions.

b. If the gallstone impaction is permanent: Tenderness in the right hypogastrium to pressure. Soreness and dragging pain in the right side. Retention cyst (dropsy) of the gallbladder, causing a slowly increasing distention of the organ which may reach enormous size, filling the right side of the abdominal cavity.

c. If the gallstone impaction is temporary: The offending body may slip back into the gall-cyst, and only a slight hypogastric tenderness mark the presence of gallstones until another attack of colic occurs. Ordinarily, dyspeptic disturbances and fleeting attacks of gall-cyst tenderness mark the interval between attacks. Occasionally a bladder filled with gallstones may be palpated below the border of the liver, and the stones thus detected, or grating sounds may be auscultated.

The offending body may pass onward into the common duct, when its history belongs in the opposite column.

Common Duct Syndrome.

a. Attacks of gallstone colic, paralleling the contrasted condition, except that the pain is referred to the right hypochondriac and right subscapular or right shoulder regions.

b. If the gallstone impaction is permanent: Tenderness and discomfort in the right hypogastrium. Jaundice. Bile in the urine. Absence of bile in the stools. Stools fatty, white, offensive. Constipation. Enlargement of the liver. Slight distention of the gallbladder. Pulse slowed to 60, 50, or even 40. Nervous symptoms of choleraemia.

c. If the gallstone impaction is temporary: The offending body passes onward into the duodenum and may be washed from the stools. It leaves a lingering tenderness in the hypogastrium. The liver shows temporary enlargement; there may be temporary jaundice, and distention of the gallbladder. Constipation is common, and the stools and urine show more or less change, temporary in character. The symptoms due to the stones remaining behind are similar to those of the opposite condition.

TREATMENT.

Gall-stone colic with temporary impaction never demands operative interference, though one is sometimes seriously tempted to resort to this radical means of

relieving the intense suffering. The treatment is necessarily symptomatic, and is identical whether the impaction be of the cystic or of the common duct. Frequently recurring attacks, even if temporary, will justify removal of the stones remaining in the gallbladder, thus bringing a surcease of the attacks by cutting off the source of supply.

Permanent impaction of either the cystic or the common duct almost always demands surgical relief. When the cystic duct is the seat of the obstruction, a vertical incision along the outer border of the right rectus, beginning just below the costal arch, or, in case of great enlargement of the gallbladder, somewhat lower, exposes the gallbladder. After walling it off with sponges, while it is held in the abdominal wound, a trocar is plunged into it and the fluid contents withdrawn. A vertical incision enters its cavity, and the gallstones present are scooped out or expressed. The stones forced into the neck of the sac and the obstructing one in the duct are squeezed back into the cavity by external digital manipulation, and so removed. If there remains no doubt as to the removal of all the stones, the incision into the gall-cyst may be closed with chromicized catgut, and the abdominal incision closed with or without drainage. Otherwise, as is commonly the case, the edges of the gallbladder-incision are stitched to the peritoneal edge of the abdominal wound in its upper angle, drainage inserted into the cyst, and the abdominal incision closed below. Of course, should there be any suspicion that the retention cyst had become empyematus, drainage would be unfailingly indicated.

When the common duct is the seat of the obstruction the course pursued differs in the method of dealing with the impacted stone. If soft it may be crushed between the thumb and fingers or the properly cushioned blades of compression forceps. But usually an incision through the wall of the duct over the impediment must be made, and the stone extracted, after which the opening into the duct may be closed with fine sutures or be allowed to close spontaneously. Whether sutured or not, a strip of gauze, and a glass or rubber drainage-tube should be led down to it for 48 hours as drainage and excitant of protective adhesions. Some difficulty is likely to be experienced in locating the obstructing body, especially if inflammatory adhesions have obscured the anatomical field. If the stone cannot be found and removed, or the condition of the patient makes haste necessary, a cholecyst-enterostomy is the procedure of choice. (Cholecystostomy is a palliative measure which conditions may force upon the operator, but it must always be looked upon as a surgical misfortune, the lesser of two evils.

DIAGNOSIS OF MEDICAL AND SURGICAL DISEASES OF THE LIVER AND BILIARY PASSAGES.

By JOHN HERR MUSSER, M.D.,

of Philadelphia.

THE time has come when the practitioner who devotes himself to internal medicine must share the responsibility of the treatment of many diseases of the liver and biliary passages with the surgeon. As the therapeutics of the latter is decisive, terminating in the cure or the death of the patient, a corollary to the above axiom should read that both should share in the diag-

nosis. I may be permitted with pardonable pride to refer to the share it was my lot to contribute in the development of the mutual labors of the physician and surgeon. The occurrence of many cases of death from affections of the biliary passages had demonstrated to the writer the woful lack of means at his command to relieve the patient. As early as 1884 I asked for the joint attendance and the operative skill of the surgeon. After 2 cases had been treated, Dr. Keen and myself published the result of our experiences and presented an analytical study of all the cases of surgery of the biliary passages then recorded. We collected 35 cases by 15 operators, upon which to base our conclusions. The paper was the first general and systematic discussion of the subject. What its influence was upon the development of hepatic surgery, it is not within the province of this paper to relate. Feeble though the effort may have been, in the light of the stupendous results since accomplished, it is a source of no little gratification that the writers' were instrumental in contributing this mite to the therapy of hepatic disease.

Medical and Surgical Diseases of the Liver.—A review of the province of each in the domain of hepatic therapy is not without interest. To the physician belongs, for complete relief or alleviation the congestions, the inflammations, including syphilis, and excluding single abscess of the liver, the degenerations and multiple morbid growths. To the surgeon, abscess of the liver, hydatid disease and single tumors. Of the cases belonging to the first class the physician may well say "hands off," while to the second class the sooner the surgeon's hands are on the better for the patient.

Diagnosis: The distinction of the two classes can generally be made with ease. Usually general principles of diagnosis go the longer way towards the distinction. Liver diseases are usually secondary to some causal morbid process elsewhere; as the congestions, to heart disease; or as amyloid disease, to some chronic infection; or they are secondary to a similar process elsewhere, as carcinoma or as abscess in the portal area. Other affections, as the chronic inflammations, follow a cause, which often can be definitely ascertained. No diagnosis of a particular hepatic disorder can be safely made without definite knowledge of the etiology of the disease in question. Moreover, the lesion of the liver is associated with allied lesions of other organs; hence their presence is sought for in the diagnosis, as amyloid disease, syphilis, or the congestions. Then the age, the sex, and the habits, and the previous medical history tally in the various affections. The differentiation of hepatic disease in the black is more difficult than in the white race.

To illustrate the foregoing: Knowledge that the patient had had dysentery, with the only other suggestive symptoms of pain in the lower thoracic region and enlargement of the liver led to the diagnosis and successful treatment of a case of abscess of the liver.¹

The surgeon must see to it that the supposed abscess of the liver is not really due to syphilis,—that the solitary tumor (adenoma usually) is not syphilitic or a deformity of the liver (Reidel's), or amyloid degeneration in a deformed liver.² Abscess of the liver is simulated by syphilis in those cases, not unusual, in which the liver enlarges rapidly and the temperature is of the hectic

¹ Musser and Keen, Cholecystostomy, *American Journal Medical Sciences*, 1884.

² Musser and Willard, Abscess of the Liver, etc., *Trans. Phila. County Medical Society*, 1893.

³ Musser, Amyloid Disease of the Liver, with an Abnormally Enlarged Left Lobe, *Pennsylvania Medical Journal*, 1899.

type.⁴ Much more difficult is the diagnosis when syphilitic proctitis happens to be present at the same time.

Hydatid disease of the liver may be suspected by the surgeon if the patient is resident in the region in which this affection prevails, if the disease is of long duration and the symptoms are negative, enlargement of the organ not usually uniform being the only physical one. Suppuration of the cyst presents a new picture of the hydatid affection and brings it into the class with abscess.

In the consideration of the diagnosis, the possibility of the symptoms being due to disease outside of the liver must not go unchallenged. In the classical work of Murchison are named the many affections which simulate enlargement of the liver including pulmonic, pleural and pericardial diseases, diseases of the intestines, of the kidney, of the aorta, of the ovary, and of the omentum. Of greatest importance is the recognition of abscess beneath the diaphragm. The fever, the pain, the physical signs closely simulate the hepatic infections, but, as Mason, Osler, and others point out, the history, and the mode of onset are far different. Then the dislocation of organs and the frequent phenomena of combined air and fluid in a cavity are strong corroborative evidences of the pus being in the subdiaphragmatic space.

Finally, we must not decry as aids to the differential diagnosis, the exploratory puncture and the results of the examination of the blood.

Medical and Surgical Diseases of the Biliary Passages.—To the former belong acute and chronic catarrhal inflammations, suppurative angiocholitis and the inoperable forms of cancer and mild forms of cholecystitis (catarrhal). As chronic catarrhal inflammation is usually due to gallstones it may be classed with the second group, to which also belong obstruction and stenosis of the biliary passages, cholecystitis, rare forms of localized carcinoma, and cholelithiasis.

Diagnosis: Acute catarrhal inflammation of the biliary passages is usually recognized with ease. Its occurrence somewhat suddenly in young, previously healthy subjects, following exposure to cold and wet or indiscretions in diet, with symptoms of catarrh of the stomach and intestines, without emaciation, with moderate icterus and lasting but a short time, renders the diagnosis one of little difficulty.

Chronic catarrhal inflammation is due to obstruction either by gallstones, carcinoma, or external pressure, and is attended by the symptoms of obstruction, especially chronic jaundice. Pain is present if gallstones is the cause.

If the obstruction is incomplete, hepatic intermitting fever may be present; if complete, fever is usually absent. As an example of complete obstruction we have the group of cases resembling the clinical picture of cancer of the pancreas. In complete obstruction, the gallbladder is enlarged. The following case (abstract) illustrates well the phenomena of incomplete obstruction and shows very well the resemblance to obstruction by gallstones. It was a cholangitis secondary to carcinoma.

McM., a woman, aged 37, married, had been ill for many years with hepatic pain, nausea and vomiting, intermitting fever and occasional jaundice. The last illness, which terminated fatally, was of six months' duration. Pain in the region of the gallbladder, intermitting fever, jaundice, and vomiting, were present. The pain and jaundice were inter-

mitting. Death took place from exhaustion. At the autopsy there was found cholangitis and carcinoma of the gallbladder.

General suppurative cholangitis is attended by the symptoms of local infection, by tenderness of the liver with enlargement of that organ and of the gallbladder, by jaundice with the occurrence of leukocytosis. The duration is not long and the formation of multiple small abscesses is likely to follow. The patient rapidly loses flesh and strength. Such cases may be classed as surgical, only with the vain hope that the inflammation is due to gallstones.

Inoperable cancer of the biliary passages is that which involves the gallbladder alone or the gallbladder and the gall-duets. It occurs in women in three out of four cases, usually between the ages of 40 and 70, and in association with gallstones in 90%. The general symptoms of cancer are present, sometimes symptoms of catarrhal cholangitis, while jaundice (69%), pain, severe, often paroxysmal, and tumor, are frequent accompaniments. The tumor is hard and firm and with it may be recognized an enlarged gallbladder.⁵

Of the surgical diseases of the biliary passages, we have considered *chronic catarrhal inflammation*. This affection may, when there is satisfactory evidence to do so, be dealt with by the surgeon. The presence of gallstones as causal factors will permit of exploratory measures at least. After gallstones, chronic catarrhal inflammation is the most frequent cause of chronic jaundice.

Stenosis and Obstruction of the Gall-duets.—The cases are very puzzling. Disease of the ducts, as cancer or cholangitis, external pressure or internal obstruction by stones or worms. They are often classified as cases of chronic jaundice. If they have been preceded by a definite attack of gallstones, the occurrence of ulceration followed by stenosis may be surmised. Cholecystitis with pericholecystitis forming adhesions about the ducts may cause these symptoms. On the other hand, symptoms of pancreatic disease, of disease of the lymphatic glands, as cancer secondary to cancer elsewhere in the abdomen, of renal or omental disease, or of an aneurysm, may indicate the true cause of the external pressure.

General considerations must guide in the diagnosis. Evidence of enlarged lymphatic glands elsewhere or cancer in other parts must be sought for. To exclude cancer of the liver it must be borne in mind, the liver is usually enlarged at first, but later may atrophy in chronic obstruction of the duct, while in cancer of the liver it continues to enlarge; that in chronic obstruction the gallbladder is enlarged, except in cases of gallstones. To this interesting group of cases belongs that symptom group caused by a ball-valve-acting gallstone, with which chronic catarrhal cholangitis is associated.

Cholecystitis.—Catarrhal, suppurative, and phlegmonous forms are seen. The varieties may be associated with gallstones and a possible infection, or they may be due to bacterial invasion primarily. The local symptoms are severe at first. Paroxysmal pain in the right side resembling that of gallstones, although not so severe or prolonged, and later localized to the region of the gallbladder, is first complained of. There is muscular rigidity in this region; tenderness at first diffused, then localized; some abdominal distention. The gallbladder may be felt in some cases, or marked out by percussion. In the suppurative form Robson lays stress upon the tender spot "at the junction of the upper two-

⁴ Musser, Fever in Late Syphilis, *University Medical Magazine*, 1892.

⁵ Cancer of Gallbladder and Gall-duets, Musser, *Trans. Assoc. Physicians*, 1889.

thirds with the lower third of a line drawn from the umbilicus to the ninth rib." Nausea and vomiting occur and at times there are symptoms of intestinal obstruction. The history of gallstones or of an infection within reasonable time, as the typhoid or pneumococcus infection, or a more localized one from the colon-bacillus or the streptococcus, as indicated by infection somewhere in the abdominal cavity, may explain the symptoms. If the inflammation is simply catarrhal the general symptoms are not marked; if suppuration is present there is high fever, rapid pulse, and much prostration. Often, however, the diagnosis of the varieties is impossible. The variety due to gallstones is more likely to have jaundice than that due to bacterial invasion. Regarding the distinction of the catarrhal and suppurative forms we are in the same position as to operative interference as in cases of catarrhal and suppurative appendicitis. Cases of acute infectious cholangitis with suppuration get well without operative interference. Thus, in 1889, Mrs. D. had typhoid fever. Two days after the temperature was normal she had a rigor followed by fever. Thereafter for two weeks rigors occurred daily with fever of several hours' duration. Pain and tenderness were extreme in the hepatic region. Jaundice ensued. Rigidity of the abdominal muscles, swelling and edema of the walls took place. Fever became continuous and the tympany extreme. Recovery followed at the end of four weeks' illness, after a number of evacuations of pus per anum. On the other hand, death occurred in a man of 70, with intermitting fever, jaundice, and tumor. At autopsy, gallstones with ulceration were shown to have caused the cholecystitis and peritonitis.

Carcinoma of the Gall-duct.—Not as frequent as similar disease of the gallbladder, the course is more rapid. Three cases have come under my observation. The duration of symptoms ranged from 3 to 8 months. They were in females. In two the course was rapid, attended by jaundice, enlarged gallbladder and by cachexia. Death in both was due to gastrointestinal hemorrhage. The diagnosis was based upon the age, the absence of history of gallstones, the emaciation and prostration, the intense jaundice, the absence of fever, the enlarged gallbladder, the normal size of liver, and the absence of malignant disease elsewhere.

Gallstones. Cholelithiasis.—A volume could be written on the clinical course of these marauders, for such they become when they wander. (a) They may be present and not cause symptoms. (b) They may cause pain, (biliary colic). (c) They may cause obstruction of the cystic duct followed by: (1) Hydrops of the gallbladder; (2) cholecystitis, simple and suppurative (empyema of gallbladder); (3) atrophy of gallbladder. (d) They may cause complete obstruction of the common duct (1) without pain; (2) with pain. The symptoms of obstructive jaundice previously described, follow—jaundice with its train of symptoms being the chief phenomena, without pain, or with recurring attacks of pain. There is no infection. (e) They may cause: (1) Incomplete obstruction with symptoms due to ball-valve action of the stone or (2) to suppurative cholangitis. An infective cholangitis is present in both instances, but in the latter it is diffused and death occurs early. In the former the duration is from 2 to 5 years. In two of my cases ascites was present, and in one an enlarged gallbladder, contrary to the general rule. In other respects they conformed to the types portrayed by Osler: Hepatic intermitting fever, jaundice intermitting in intensity but persistent, pains of a paroxysmal

character. In one instance there was severe hematuria at various times and almost constantly subcutaneous hemorrhages for 8 months.

CASE 1.—Mrs. K., aged 77, had repeated attacks of biliary colic. After one, there was jaundice, which persisted and increased at each subsequent attack, with which nausea and vomiting also occurred. Some emaciation took place. The duration of the jaundice was two years, when ascites developed. The gallbladder was palpable. At the end of six months or two-and-one-half years after jaundice, death occurred from exhaustion. Hepatic intermitting fever occurred irregularly. Itching was intense. Operation was refused, and there was no autopsy.

CASE 2.—Mrs. V., aged 57, married, has children, leads a sedentary life, and her habits are good. Her father died suddenly; her mother died of heart-trouble, but was always bilious and had liver-trouble. The patient was always delicate and seemed to have weak circulation. In 1891 she had jaundice, epigastric pain, some vomiting (two weeks), extreme with hemorrhages, with a tumor easily felt above the navel in the middle line about the size of a lemon. She has lost much flesh. The diagnosis was cancer of stomach. Since then recovery has taken place until in 1897 when she had an attack of catarrhal jaundice which lasted seven weeks. In 1870 she had pulmonary hemorrhage. She has had mitral valvulitis, so her physician reports. Her present illness began in September, 1899. Jaundice continued and was very extreme. She was relieved by December, to be followed in October by purpura. In February there was a recurrence, which has not been relieved. In February there was general purpura; there was no fever and no chills at any time, and no vomiting. There were clayey stools and the urine was high-colored. At present (April 12, 1900) there exists chronic jaundice of the conjunctiva and skin, and pruritus is extreme, with scratch marks. The skin is dry. A few purpuric spots exist. She has lost flesh, 17 pounds, which is below normal. Lately there has been less jaundice. Appetite is fair. The bowels are constipated (always so for years); and there is flatulence. Liver is not enlarged. There is an obscure small lemon-sized hard mass deep in the gallbladder region. The abdomen is pendulous, the spleen is not enlarged, and no ascites exists. There are some hemorrhoids, but no edema. Hemoglobin 75%; red blood-corpuscles, 3,728,000; white blood-corpuscles, 7,200; urine shows trace of albumin, bile and hyalin casts.

There was general jaundice and purpura with recurrent paroxysms of jaundice attended by renal hemorrhage. There was a tumor in the right hypochondriac region. Renal hemorrhage lasted nine days. At first she had pain in the region of the left kidney. There was one paroxysm of hepatic colic followed by a sensation of giving away, and then followed a diminution of mass on the right side. She has lost eight pounds. There was no fever until after improvement, when the temperature rose not higher than 99.2°. There was marked anemia. Hemoglobin, 65%; red blood-corpuscles, 3,392,000; white blood-corpuscles, 6,000. The urine contained albumin and no bile. There were a few hyalin and granular casts.

On July 7 she was still losing flesh, and was darker in color. The pruritus was very severe most of the time, and at times caused her to be very nervous. The bowels were loose and the stools of clay color. There was some edema of the lower limbs. The mind was not so clear. The liver was enlarged, especially the left lobe. The gallbladder was enlarged and tender, ascites was marked. Hemoglobin, 45%; red blood-corpuscles, 2,670,000; white blood-corpuscles, 6,000; urine as previously reported.

At the autopsy a ball-valve gallstone was found with biliary cirrhosis of the liver.

Before dismissing the subject of gallstones, we may be permitted to call attention to one or two facts in variance with the commonly accepted notion of their clinical concomitants.

1. Gallstones may occur at an earlier age than we usually suppose. A man, aged 23, was operated on by Dr. Martin for me, and 200 calculi removed. He had hepatic colic from his fifteenth year.

2. Pain may be the only symptom. It may be in various localities. In a case I saw with Dr. Sprengel (operated on by him) the pain was seated at the xiphoid cartilage.

3. Jaundice may never be present.

4. Rigors and fever may be the most pronounced symptoms, pain complained of very slightly.

5. Of great importance, as an indication of their presence, is the occurrence of persistent localized tenderness in the gallbladder region, often elicited only on deep palpation when the patient takes a full breath. Gallstone crepitus may be felt, and Dr. Anders reports cases in which he heard it.

As with hepatic disorders so with surgical affections of the biliary passages; they must be excluded from affections outside of the bile-ducts which they simulate. Of these, subdiaphragmatic abscess, appendicitis, intestinal obstruction and acute pancreatitis are the most common.

The first is frequently, due to the biliary infection or arises from perforation of other hollow viscera and has a group of physical signs of its own, of which dislocation of the liver is one, not present in simple biliary channel infections. It can usually be distinguished. Appendicitis is not so easy to differentiate, and in fact is impossible to exclude in some cases. Intestinal obstruction likewise is simulated by the biliary disorder, but may, although not easily, be excluded by the efforts to move the bowels and by the absence of the extreme shock and peristaltic intestinal waves and of the symptoms peculiar to each variety of obstruction. Pancreatitis presents similar symptoms to those of cholecystitis. Febrile symptoms are not as marked, however, while collapse symptoms are more dominant in pancreatitis. The circumscribed epigastric swelling which is usually tympanic is suggestive of pancreatic disease. In a case operated upon for me by Dr. Morton the symptoms were those of cholecystitis and hepatic colic. The pancreas was found enlarged and hard, the gallbladder normal. No symptoms have ensued since the operation three years ago, when the attacks were due to pancreatitis, no doubt, although closely resembling biliary colic. Gallstones, on the other hand, may be simulated by hysteria, acute flatulent dyspepsia, appendicular colic, renal colic, liver colic, pain in the intercostal nerves from osteitis of the spine, malignant disease of the liver and pyloric obstruction. We cannot enter into a discussion of the differential points of the various affections. Pyloric obstruction is the one more commonly seen to present symptoms of biliary colic, especially if the stenosis is due to adhesions about the gallbladder. The characteristic vomitus and the physical signs of dilation of the stomach make the diagnosis of the former almost positive.

A few more clinical data are suggestive in the diagnosis. The surgeon must be chary concerning the diagnosis of cholecystitis and its operative interference in all cases in which the liver is enlarged, even though jaundice, pain, and symptoms of infection may be present. Such enlargement is likely to be due to diffused suppurative cholangitis and multiple small abscesses, or to subdiaphragmatic abscess, or to cancer of the liver, or in rare instances to forms of cirrhosis, or to syphilis of the organ.

Enlargement of the gallbladder is seen in obstruction of the cystic duct, in complete obstruction of the common duct, in suppurative cholangitis, and in cancer of the bile-ducts. It is not enlarged in incomplete obstruction

of the common duct, in gallstones, and, though distended, not necessarily enlarged in any form of cholecystitis.

Fever is absent in complete obstruction of the common duct and in carcinoma of the bile-duct. It is present in incomplete obstruction, in the infections and in gallstones.

The spleen is enlarged in biliary colic and in incomplete obstruction of the ducts with cholangitis.

Jaundice is more frequently absent than present in cholecystitis. It is often absent in gallstones. It is not present in cystic obstruction. It varies in degree in incomplete obstruction and is very intense in cancer of the bile-ducts.

Pain is indicative of gallstones, of suppurative cholangitis and cholecystitis. It is absent in complete obstruction from external pressure or from cancer of the bile-ducts.

Indications for Operation.—In the paper previously referred to (Musser and Keen) the indications for operation suggested were pain, tumor, jaundice due to obstruction of the common duct, and symptoms of suppuration. Such indications obtain at the present day. Concerning pain it may be said now as then, an operation for its relief is justifiable when life is threatened by its continuance. The various conditions possible which may give rise to tumors were discussed and they tally with those which Robson points out must be distinguished from tumors of the gallbladder. They were movable right kidney, tumor of the right kidney or suprarenal capsule, of the intestine, of the liver itself, or of the stomach and deformed liver. The preceding remarks will indicate largely the lines of differentiation. To go further into detail will exceed the limits of the paper. But a word, the history of the case must be insisted upon and the customary means of exploring the stomach and intestine employed. More could be said about a floating kidney, but reference must suffice.

At this stage of surgical procedures it is not necessary to urge operation in local infections.

Contraindications.—The surgeon must watch the blood. The time clotting must be carefully inquired into. The corpuscles must be counted. A lessening of two and one-half millions makes an operation dangerous. The hemorrhages which occur in chronic jaundice are serious contraindications, yielding only to the necessity to save life.

ON LESIONS OF THE PANCREAS SIMULATING GALLSTONE-IMPACTS OF THE COMMON DUCT.

By MAURICE H. RICHARDSON, M.D.,

of Boston.

In collecting my gallbladder cases I have been struck by the frequent occurrence of pancreatic tumors discovered during explorations for suspected gallstones. In most of these cases the nature of the tumor has been sufficiently obvious; the history has strongly suggested cancer of the pancreas, and the exploration has removed the last doubt. But in some a doubt has always remained whether after all the tumor, which certainly caused the symptoms, was really malignant or not; whether the exploration had accomplished all that it might; and whether in future cases I should make more extensive dissections, in the hope of accomplishing better results.

The chief objection in doubtful cases to an explora-

tion deep enough to demonstrate beyond question the nature of the tumor has been that there is little prospect of benefit to offset the great dangers of the procedure. An exact knowledge of the tumor would not often justify further procedures, for malignant tumors of this region from their nature and environment seldom if ever permit extirpation, and others only occasionally demand it. Moreover, dissections carried into the tumor cannot but add greatly to the dangers of exploration. Hence, it has seemed as a rule unjustifiable to do more than to explore as thoroughly as possible by digital manipulation of the suspected mass, the operation being continued or abandoned in accordance with the knowledge gained by such manipulations. But the results of digital examination of the pancreas are not always convincing, though they may be very suggestive, for the normal firmness and irregular outline of an unusually large pancreas may lead to the erroneous conclusion that it is the seat of a new growth. Such faulty deductions remove the only hope of radical cure, small though that hope may be. The recent cases of Robson (*Lancet*, July 28, 1900) show that tumors of the head of the pancreas are by no means so discouraging as we have thought; and that in all probability many patients have been left to die under the impression that there was cancer of the pancreas when in reality the tumor was a chronic inflammatory enlargement that would have quickly subsided under drainage. Renewed investigation suggests, too, that some of the rarer cases of biliary obstruction may not be beyond the possibility of surgical relief.

The commonest lesion of the pancreas, in my experience, has been carcinoma of the head pressing upon or surrounding the common duct sufficiently to cause complete stenosis and permanent jaundice. In some of the cases autopsy has confirmed the diagnosis of cancer made at the time of operation; in others the diagnosis has depended upon the results of digital exploration alone. The mortality in these cases has been large, for the patients have been, as a rule, reduced to an extreme degree of weakness and emaciation. These fatal operations have consisted in simple digital exploration, sometimes through a very small incision. In a few cases the gallbladder has been opened for temporary relief. The mortality has been out of all proportion to the severity of the operation. Whether the lesion was such as to stop the flow of pancreatic juice as well as of bile cannot be said in any of these cases. It is reasonable to conclude, however, that this occlusion occurred in some at least of them.

My interest in this subject was first excited by the following case:

CASE 1.—Mr. A. O. B., aged 43, a patient of Dr. C. P. Hooker, of Springfield, had typhoid fever in 1891. He did not return to his work for three months. In the following year (1892) in April he was seized in the night with severe pain in the pit of the stomach. He could neither lie down nor stand. This pain lasted three or four hours. There was no jaundice. From this time till March, 1895, he had several attacks similar to the first. These were called neuralgia and indigestion. In March, 1895, he had an attack of severe pain which was followed by jaundice. In August there was another severe attack. Between March and August there were several slight ones. The weight had diminished from 170 pounds in 1891 to 145 in 1895.

At the time of my first visit and operation, December 5, 1895, I found that he had been suffering for two weeks with an attack beginning as before with pain in the pit of the stomach, followed by jaundice. There were no physical signs in this case beyond jaundice, loss of weight, and cachexia.

The diagnosis was gallstones, with a strong probability of cancer of the pancreas associated with them.

The exploration showed a tumor of the head of the pancreas. This was carefully and repeatedly examined. It seemed so evidently a case of malignant disease that the operation was abandoned. The gallbladder was not opened. The patient recovered well from the exploration and put himself into the hands of a cancer doctor. He not only began to improve, but continued to improve until he had recovered his health perfectly. He has remained well ever since, and is now at work in a town in Connecticut. I have since thought that the digital manipulations of the pancreas made during my repeated examinations may have dislodged a stone and forced it into the duodenum, as in Case III. Under this supposition it seems not unreasonable to suggest that the stone was beyond the junction of the pancreas with the common duct, and that the enlargement of the pancreas may have been due to obstruction of the canal of Wirsung with engorgement and possibly other changes in the gland.

In this case the previous history pointed to gallstones,—the sudden seizures of pain; its sudden cessation; the frequently repeated attacks, similar in character but of varying severity; the onset of jaundice with the later seizures. In the history nothing suggested acute or sub-acute pancreatic disease. The symptoms, if dependent upon some mild lesion of the pancreas, did not permit a diagnosis. The loss of weight, with the jaundice, the cachexia, did suggest the possibility of malignant disease of the pancreas,—these symptoms always do,—but not the possibility of any curable lesion of that organ.

The unexpected recovery of this patient has increased the feeling of uncertainty whenever I have discovered in the course of operation for gallstones an enlargement of the pancreas along the course of the common duct. As a rule, when the diagnosis of cancer has been made at the time of exploration I have closed the abdominal incision without opening the gallbladder, because of the discomfort of the biliary fistula, which cannot but persist when the common duct is completely and permanently obstructed. When, however, gallstones have been detected in the gallbladder, I have removed them unless the patient has been too feeble to justify an operation which, from the nature of things, could be only palliative.

The number of cases in which I have found an enlargement of the pancreas supposed to be malignant has been considerable,—the number in which it was suspected before operation, even greater. The mortality has been excessive in these operations,—so great, in fact, that exploration has seemed at times hardly justifiable when the symptoms have advanced to that extreme degree so often seen after prolonged jaundice and progressive emaciation. But not a few patients have made complete recoveries after operations undertaken under quite as unfavorable conditions, due not to cancer but to gallstones; hence exploration has seemed imperative in every doubtful case.

The uncertainty entertained after digital examination of an enlarged pancreas has led in one or two instances to the hope that after all the disease was benign,—an unusually large and hard gland, a simple hyperplasia, a chronic inflammation, a cyst with tense walls, a subsiding hematoma, an atrophying gland, a mild and transitory infection through the canal of Wirsung. Such lesions of the pancreas are by no means unknown. Though tumors of the pancreas are unusual upon the autopsy table, enlargements of the gland are not infrequently found in the course of abdominal explorations upon the living. Doubtless many of these enlargements are temporary; many may come and go without even

being suspected, their symptoms being referred to indigestion and their presence being beyond detection. The commonest form of jaundice—the painless gastrointestinal catarrh which checks temporarily the flow of bile—may be but a mild form of that lesion which in extreme development may cause a temporary infective engorgement of the pancreatic duct and tissues. Such a possibility is largely theoretical, yet it is not unreasonable to suppose that infection may take place through the canal of Wirsung, and that that infection may be a mild one, giving rise to those indefinite pains and discomforts in the upper abdomen which so often accompany complete obstruction of the biliary stream. A pancreas affected enough to compress the common duct may be impossible of detection by palpation—it may even be difficult of detection with the fingers during an exploration. A pancreas as large as one's fist may not be perceptible before exploration, especially in stout and muscular patients. An organ so deeply situated may be, for all that we know, especially liable to mild affections attended by actual changes in size and consistency which we may never even suspect.

Such a possibility has seemed not unreasonable, in view of the frequent observations made upon the living during exploratory operations for obscure conditions in the region of the biliary tract. From the evidence of postmortem examinations only it must be concluded that changes in the pancreas causing stenosis of the common duct are usually malignant and beyond aid. Assuming the frequent occurrence of the mild and temporary changes in the pancreas, however, and remarking the absence of such changes upon the autopsy table, it must be concluded that these mild changes are usually self-limited and curable, and that they have little importance in the discussion of surgical questions connected with the pancreas, except as a possible explanation of those attacks of transitory jaundice upon which a mistaken diagnosis of gallstones is occasionally based.

It is, however, with those chronic pancreatic enlargements, which threaten life by encroaching upon and closing the common duct, that surgeons are chiefly interested. Are there lesions which closely simulate cancer and which, unrelieved, will cause death, but which by so simple an operation as cholecystotomy may be cured? May we hope by surgical measures to effect a cure either by removing the disease itself or by counteracting its effects? It must be admitted that the pancreas is the seat of lesions which resemble cancer so closely that discrimination is impossible, even when the gland is palpated between the fingers. Pathologists have long warned observers against mistaking such a pancreas for malignant disease.

Friedreich, in Ziemssen (Vol. VIII, p. 564) says:

Even in 1713 Holdefreund believed that the pancreas was more often the seat of cancerous induration than any other organ in the body, and this leads to the suggestion that the gland, on account of its compact, granular appearance, has often been considered indurated, while it was really normal. In the presence of such views, it behooves us to use the greatest care before utilizing any data furnished by older writers bearing on the pathology of diseases of the pancreas. Later physicians have come to an opposite opinion as to the relative frequency of these diseases, and Baillie assures us that during many years of active practice he had only seen one single case in which pancreas disease was verified by postmortem examination.

Though cancer of the pancreas is a rare disease, yet the frequency with which the question of its presence

arises in gallbladder surgery is in striking contrast with the percentage of this disease in autopsy records. "At the General Hospital in Vienna in 18,069 autopsies were 22 cases of cancer of the pancreas (Biach.) At Milan Segrè found 127 in 11,472 autopsies. At the Johns Hopkins Hospital, 5 adenocarcinomas were found in 1,000 autopsies. At Guy's Hospital, 20 cases of primary malignant disease of the pancreas were found in 6,000 autopsies." These figures are taken from Osler's *Practice of Medicine*, page 594.

Of 23 fatal gallbladder operations of my own, cancer of the pancreas was found in 5. The total number of cases in which cancer was suspected but not demonstrated was considerable. The percentage of cases would seem large in comparison with the figures taken from Osler, but it must be remembered that in all the cases, whether explored or not, the symptoms pointed strongly to cancer of the pancreas,—all the cases were either biliary or pancreatic. The percentage of cases in comparison with the total number of abdominal operations is small, and small in comparison with the total number of operations for malignant disease generally. From the standpoint of comparative rarity, then, it may be argued that in a certain percentage, at least of suspected cases—or even of apparently demonstrated cases of pancreatic cancer—the diagnosis may have been wrong, and that surgical intervention was not as hopeless as it seemed.

The following cases illustrate a combination of symptoms strongly indicating gallstones, but also suggesting malignant disease. Gallstones were found at the autopsy, with a cyst of the pancreas and doubtful malignancy.

CASE 2.—W. A. R., a gentleman of 64, I saw on November 3, 1897, at Worcester, in consultation with Drs. Robinson, Homer Gage and Fay, of Worcester, and Dr. Stevens, of Cambridge. The patient had suffered many years with cardiac disease—mitral insufficiency with hypertrophy. For two years he had been subject to "bilious attacks" with jaundice—evidently gallstone colic. Each attack was attended by a jaundice which lasted about three weeks. Between the attacks he would regain his usual health and attend to business. No gallstones had ever been found in the stools. At no time were the physicians able to detect the gallbladder. There was a fulness in the region of the right hypochondrium that extended toward the epigastrium. There had been a loss of 60 pounds in weight, 5 of which had been regained previous to his last illness. The present attack began on the 15th of September, 1897, with intense pain in the right side. This was shortly followed by jaundice. A week later the patient suddenly became collapsed. He was livid and unconscious. As soon as he became conscious he complained of intense pain. Operation had been considered during previous attack, for the physicians had no doubt that the symptoms were caused by gallstones. On account of his heart, however, it was decided best not to operate.

I found this gentleman deeply jaundiced. It was not the common color of jaundice; the skin was very dark—almost black—a combination of cyanosis and jaundice. Nothing could be detected in the region of the gallbladder or in the abdomen. The heart-sounds were very weak, the pulse was irregular; there was no fever. He was extremely emaciated. There was no ascites. The history in this case pointed definitely to a gallstone impacted in the common duct. The absence of stones in the stools indicated probably a transitory impaction of a permanently lodged stone, the stone acting as a ball-valve, occasionally receding and occasionally advancing. The great loss of flesh, however, suggested the possibility of a malignant disease. The urine showed a combination of chronic passive congestion and biliary irritation. No operation was undertaken because of the patient's great weakness and because of the serious cardiac complication. The disease was evidently a fatal one, and no benefit could reasonably be expected from operation.

At the autopsy a large stone was found in the gallbladder;

another was found impacted at the common duct, $\frac{3}{4}$ cm. from the duodenal papilla. The pancreas itself contained a small cyst filled with a reddish jelly-like material, surrounded by disintegrated pancreatic tissues. Malignancy could not be definitely established, either by gross appearances or by the microscope. It was a cyst of the pancreas with other changes in that organ of doubtful character, associated with gallstone impacted in the common duct, the whole complicated with disease of the heart.

The diagnosis between impacted gallstone and carcinoma and other disease of the pancreas is always difficult and usually impossible. In cases like the one just given, recognition of the lesion is of course out of the question. The history of the case pointed clearly to gallstone; the peculiarity of the jaundice and great emaciation, toward malignant disease. A combination of both would not have seemed extraordinary, and a diagnosis would not have been unusual. The real lesion in this case could not have been predicted. A combination of gallstone and cyst of the pancreas, whether malignant disease is present or not, would seem not improbable, especially if the obstruction to the pancreatic duct was prolonged. In 5 large cysts of the pancreas upon which I have operated there were no symptoms referable to the liver, and no stone or other cause of obstruction was found in the pancreatic duct.

Another case illustrates not only the difficulties of diagnosis, but other points in connection with the subject.

CASE 3.—This was a gentleman of 62, of Goffstown, New Hampshire, a patient of Dr. George. I saw him on the 7th of July, 1899. He was a manufacturer, of good habits, subject to sick-headaches. In February of that year he had an attack of what was supposed to be gallstone colic which lasted an hour or two. The second attack occurred in the course of a week, and the pain was very severe. It was described as a "screamer," lasted from six in the morning till six at night, and required ether. From this attack he slowly recovered and got about his business, and was able to go South, where he stayed until June. After his return he developed malaria, chills, fever, and sweating. Five days before my visit he was taken with another attack of gallstones. With all the previous attacks he had had slight jaundice which quickly disappeared. The jaundice this last time appeared soon after the pain and persisted. There was some loss of weight. There was no appetite. There were nausea and vomiting. No gallstones had ever been found in the stools. He never had had any illness except typhoid fever, and he had never had pain in the abdomen before these attacks began; during the previous winter he had been troubled with diarrhea that weakened him a good deal.

I found this patient very much prostrated and despondent. He had been vomiting every day. The temperature during the attacks had been up to 103° ; the pulse from 100 to 110. At my examination I found a tender tumor in the region of the gallbladder. There was no ascites. The pulse was 64.

The history of this case pointed strongly to gallstones. The jaundice, loss of weight, and the general appearance of the man could be ascribed to something more serious. The diagnosis was gallstones with strong probability of cancer. No gallstones were found in the gallbladder, but a stone was detected in the pancreatic portion of the common duct. The head of the pancreas itself was indurated, but it did not suggest malignant disease. The stone in the duct in the pancreas could easily be felt between the thumb and finger. In manipulating the stone it became crushed and the fragments were easily squeezed into the duodenum. This patient made a rapid recovery from the operation, and some months afterwards reported himself in the best of health.

It will be seen that the history of this case was very suggestive of gallstones. In spite of this history I undertook the operation with great reluctance, for the prognosis seemed extremely grave. The written description of this man's condition gives no adequate idea of the real aspect of the case. Many times when the diagnosis

lies between impacted gallstones and malignant disease the indescribable general appearance may incline toward one or the other of the two possibilities. In this case the history of gallstones predominated so strongly that the opinion was correspondingly influenced toward the diagnosis of gallstones. Yet it was almost as surprising to find gallstones alone as it would have been to find malignant disease alone. More probable than either diagnosis seemed a combination of the two.

In the diagnosis between a gallstone impaction and cancer of the pancreas, ascites with jaundice favors cancer. Gradual loss of weight and the absence of pain are strong confirmatory signs.

The absence of pain is significant of simple pressure upon the common duct and therefore favors a new growth in the pancreas. Yet the absence of pain is not incompatible with the presence of a long-impacted stone if there was a distinct attack of sudden pain in the beginning. The element of suddenness in the appearance of the jaundice, too, is important as indicating a stone rather than a neoplasm. A gradually-appearing jaundice is certainly indicative of a neoplasm in the pancreas, if jaundice can ever be called gradually appearing. Jaundice can hardly appear until the duct is almost totally occluded, for sufficient bile can escape through a very small opening to keep the biliary passages effectually drained. This is frequently demonstrated in minute biliary fistula. It is only when the flow is arrested sufficiently to prevent the greater part of the secretion from escaping into the duodenum that jaundice appears. This condition of partial obstruction is capable of demonstration, for moderate jaundice is then attended by a certain amount of color in the stools.

Changes in the stools peculiar to diseases of the pancreas should be noted, for their presence may definitely establish the diagnosis. The value of this evidence must not be overestimated, however, because extensive lesions of the pancreas may exist without perceptible effect upon the processes of digestion. When such effects are perceptible, the conclusion that the pancreas is diseased is fully justified.

In the class of cases under discussion those symptoms which make malignancy unmistakable need no consideration, for in such cases surgery has no concern. Not that the surgical treatment of pancreatic cancer may not be considered in the very earliest stages of that disease, discouraging and unjustifiable though it may seem, but operation cannot be seriously proposed when ascites, tumor, emaciation, and general cachexia make the diagnosis positive. It is rather the early and obscure manifestations of malignancy that simulate gallstones, and it is the symptoms of this stage that require careful study.

Unfortunately, a recognition of the lesion at this stage, clear enough to justify the withholding of a curative operation, cannot be made by any man, skilful and experienced though he may be. Confidence in his diagnosis must indeed be strong when the surgeon refuses his patient the possibilities of successfully removing an impacted stone on the ground that operation in pancreatic tumors is useless or more than useless.

In the diagnosis of chronic pancreatic diseases other than cancer, there can be little more than a guess. When such lesions as chronic pancreatitis, simple hyperplasia, calculi, cysts, hematomata, are suspected, and especially when a tumor is perceptible through the abdominal wall, there can be no certainty that the lesion is benign, even if the signs of malignancy are conspicuously absent. Even in a large pancreatic cyst success-

fully operated upon, I made the diagnosis of malignant disease. On the other hand, whether a tumor is perceptible or not, the existence of ascites, cachexia, and emaciation, is sufficient to establish malignancy and contraindicate operation on the ground of hopelessness.

In the study of suspected pancreatic disease the history plays an important part. Though little is known of the less acute forms of pancreatic disease—of sub-acute inflammations, of temporary engorgements, of slight hemorrhages, of mild infections, and of other acute and chronic processes—a history of previous attacks of obscure epigastric pains and discomforts, or of lesions in viscera contiguous to the pancreas may with existing symptoms incline the opinion definitely toward disease of the pancreas. Finally, changes in the stools peculiar to pancreatic disease, or a saccharine diabetes, may add the needed evidence in favor of the pancreas. The diagnosis of pancreatic lesions attended by enlargement and induration of the gland—simulating, in fact, carcinoma—must be a matter largely of conjecture, for a tumor which cannot be positively recognized under inspection and manipulation can hardly be diagnosed before exploration.

Of the diagnosis it may be said, then, that in obscure cases it cannot be made; that when the diagnosis of gallstone impacted in the common duct is made it by no means follows that there is not disease in the head of the pancreas; that when the diagnosis of tumor of the pancreas is made it by no means follows that there is no gallstone; that finally, when the signs of cancer of the pancreas are conspicuous there is little probability of error.

With reference to the tumor, if any is detected in the region of the pancreas, it must be admitted that it is not always easy of recognition. A tumor of the head of the pancreas may be mistaken for a deeply seated and adherent gallbladder. When the gallbladder, from the prolonged effects of gallstones, has undergone those changes in shape and direction so often seen, it may cause a tumor which cannot be distinguished from a tumor of the pancreas. Other tumors may exist in the region of the pancreas and cause error, especially tumors of the pylorus, of the colon, of the mesenteric glands; abscesses from mesentery, appendix, intestine, and stomach; extravasations, hemorrhages; examples of all of which I could give from my own records. It must be admitted then, that an exact diagnosis cannot always be made.

The indications for operation when symptoms show that the biliary flow is permanently obstructed along the course of the common duct are to explore unless the diagnosis of hopeless malignancy is clear; to explore in prolonged jaundice when there is a history of gallstones; to explore even without a history of gallstones, provided that the patient shows no cachexia; to explore when there is a tumor in the region of the pancreas without signs of malignancy. The justification for these rules, by which I am more and more inclined to be guided, lies in the prognosis of those cases when left to themselves. Gallstones impacted in the common duct destroy life unless they escape into the intestine. Even then, so slow is the natural process that they may leave permanent contractions even more difficult and dangerous of relief than the removal of the stone itself in the first instance. Moreover, the dangers during the process of ulceration into the intestine are great, and even in the intestine the gallstone may cause obstruction.

The questions arising during exploration of the

common duct undertaken for symptoms of stenosis are, first, those of diagnosis. Palpation under profound anesthesia will sometimes clear up the diagnosis. An indefinite resistance in the right hypochondrium will often be resolved into a tumor with distinct outlines and definite environment. Not infrequently the tumor will show unmistakable features of malignancy; in this case the exploration must be abandoned. Most cases,—and, in fact, all that I have operated upon,—have failed to show under anesthesia any unmistakable evidence of hopelessness. It is especially desirable in the marasmic to avoid an unnecessary incision, because of the great mortality in simple explorations for cancer, even when the incision is small and the exploration brief.

The first incision should be very short,—just large enough to admit the finger. As soon as the abdominal cavity is opened the presence or absence of serum should be noticed. Free fluid in the abdominal cavity almost invariably means malignant disease. It is well, however, if fluid is found, to pass the finger to the gallbladder, foramen of Winslow, duodenum, and pancreas, where undoubtedly cancerous nodules will be felt. In the absence of ascites, digital exploration will probably fail to demonstrate hopelessness, though it is possible even then to find sufficient evidence of hopelessness to require abandonment of further search. If, from the patient's strength or from limitation of the disease or for other reasons it seems justifiable to attempt relief of jaundice by a cholecystenterostomy in cancer of the pancreas, the operator will of course proceed to that operation. In case no contraindication is developed, the incision is next enlarged to admit the hand. Thorough examination is now possible of the whole tract between the gallbladder and the duodenum. If the pancreas seems not abnormal, a stone will probably be detected somewhere along the course of the common duct, where it may be treated as the operator may determine. I have found in two or three instances firm yellowish spots scattered throughout the fatty areas of the abdomen, especially in the omentum and mesentery. These spots have always suggested a previous fat-necrosis, and have been twice associated with changes in the pancreas. In the last case mentioned in this paper these peculiar areas were conspicuous, and, in the light of the unexpected recovery, encouraged the hope that the enlargement of the pancreas was inflammatory rather than malignant. It seems worth while, therefore, to inspect carefully the omentum and mesentery.

To examine the head of the pancreas sufficiently for guidance, it is not necessary to open the lesser omental cavity. With the whole hand in the abdomen, the head of the pancreas may be grasped between the thumb and fingers. The overlying duodenum offers but slight obstacle to thorough palpation. I use the left hand, with the thumb in front of the pancreas and toward the patient's left, the fingers to the patient's right and behind the pancreas, if possible. This position will bring the fingers against the portion of the pancreas enclosing the duct and against the duct itself before it enters the pancreas. It is not, of course, possible to grasp the pancreas anteroposteriorly, for the fingers cannot be passed behind the head of the gland. The grasp will rather be in a plane passing from the right side of the bodies of the lumbar vertebrae to the left and forward. A sufficiently large portion may be thus grasped and manipulated. In cases of doubt, I have enlarged the incision enough to use the fingers of both hands, passing those of the right in front and those of

the left behind. The overlying intestine permits the fingers to glide smoothly over the head and to detect irregularities of outline and surface, by pressing backwards against the lumbar bodies.

At this stage of the investigation it is discovered perhaps that the feel of the head of the pancreas is abnormal: there is an unmistakable enlargement—a tumor even which suggests cancer; no evidence of malignancy is at hand besides the feel of the tumor itself; secondary glands have been sought, but none found; the mass has no definite nodules of unmistakable malignancy, and none are to be detected in contiguous structures; it is simply a hard, rounded mass without irregularity; there is no fluctuation; adjacent structures are not infiltrated by it, though they may be adherent; no stone is perceptible in the common duct. What is to be done? Though no definite and unmistakable evidence of malignancy is present, it is quite possible that in the center of the mass, surrounded by changes in the gland, which, though not themselves a part of the mass, are secondary to it, is a small, hard focus of malignant disease. If a small tumor is felt in the mass, it may be instead of a malignant tumor a gallstone, the definition of which is masked by the enclosing tissues. Abandonment of the operation means absolute hopelessness, which an autopsy may prove mistaken. On the other hand, incision into the mass means a difficult and bloody dissection, and more likely than not a harmful if not a fatal one. Exploration by incising the common duct is a still more dangerous procedure, and may be quite as useless.

The possibilities in cases of this kind have been emphasized many times in my experience, and the questions that these possibilities suggest have always been disquieting. Not the least source of anxiety has been the possibility of leaving the patient to die unrelieved when a little further dissection would have saved him. But, on the other hand, it is no light matter to carry exploration far beyond the limits of safety, and to find at the end that nothing, not even the truth, has been gained by it.

In a recent case these questions arose: The gallbladder contained gallstones, but the head of the pancreas was very much enlarged, presenting a tumor the size of the fist. Nothing in the history had called attention to the pancreas; everything pointed to gallstones. After thorough digital examination of the tumor, the gallbladder was opened and the gallstones removed. To my surprise the case has followed the ordinary course of a simple cholecystotomy. The patient was entirely relieved of his symptoms and has gained in weight. The enlargement of the pancreas was probably a chronic pancreatitis. Drainage through the gallbladder, after removal of the gallstones, permitted the biliary passages to return to their normal condition, and with them the pancreatic.

Robson's article on this subject in the *Lancet* of July 28 is of extreme interest, for his experience in curing 16 out of 17 cases of chronic pancreatitis, with tumor suggesting cancer, encourages the hope that many of the cases pronounced incurable and left unrelieved may under cholecystotomy and drainage be restored to health. It is hard to understand why drainage through the gallbladder should exert so beneficent an influence. In the light of my first case—which was doubtless of this kind—cure may take place without any drainage whatever. It is hard to see, too, how opening the gallbladder can drain the pancreas, when the obstruction is close to the

duodenal papilla. Whatever may be the cause, recovery follows cholecystotomy and drainage. In the light of Robson's cases, and in the two of my own, it would seem advisable in all cases of doubt to drain the gallbladder whether it contained gallstones or not.

In other lesions of the pancreas the dissection may under exceptionally favorable circumstances be carried along the common duct until the exact nature of the stenosis can be determined; but the cases in which such an exploration is indicated must be extremely unusual. In a strong patient there is no reason why the dissection should not be made extensive enough to find the cause, and, if possible, to remove it. In a weak one there is every reason for keeping within the limits of the briefest and safest measures. With a long incision through the abdominal wall, the common duct and pancreas may be freely exposed from the right side, and delicate dissections may be carried out.

A persistent jaundice not owing to gallstones requires a thorough investigation of the course of the common duct through the pancreas. When that exploration shows the cause to be cancer, the operation must be abandoned or limited to palliation.

If the obstruction is in the duodenal papilla, as in Elliot's case, it may be remedied by operation through the duodenum. When the obstruction is probably caused by diffused hypertrophy of the gland, probably a chronic inflammation, drainage of the gallbladder is indicated; when to a benign neoplasm, a calculus, the contraction of cicatricial tissue, the operator must, after exact demonstration of the mechanical cause either attempt its removal or provide a new channel for bile by means of a cholecystenterostomy.

TWO INTERESTING CASES: GALLSTONE OF THE CYSTIC DUCT, WITH SITUS VISCERUM INVERSUS; AND GUMMA OF THE LIVER.

By FRANK BILLINGS, M.D.,

of Chicago, Ill.

THE diagnosis of gallstones of the gallbladder and gall-tracts is not always easy, and the two following cases are reported as examples of the difficulty of diagnosis in certain instances: the first one because of anomaly in the position of the organs; the second proving not to be gallstones, although the symptoms were classical:

CASE 1.—P. H., aged 64, married, a German, was a retired brewer. He enjoyed good health all his life. He received a gunshot wound of the left shoulder during the War of the Rebellion, from which he recovered, and reported for duty within 6 weeks. In 1894, he suffered from pleuropneumonia, from which he made apparently a recovery in 3 weeks. His father died of typhoid fever, and mother of cholera. Of 3 brothers, 1 died of a gunshot wound during the war, and 1 of consumption. One is living, and in good health. All of the sisters are living and well; otherwise, the family history is negative. The patient has used tobacco to excess in the past, but uses it moderately at present. He has always used alcoholics to excess.

His present illness began suddenly in the fall of 1895. He was seized with severe colicky pains in the epigastrium which radiated over the entire abdomen. There was great depression, without nausea or vomiting; a chill followed by fever occurred, and the next day there was slight jaundice. Morphine was required to allay the pain. Two more attacks, similar in nature, occurred within the next two weeks, in all of which there was slight jaundice, chill, and fever, and morphine was required to relieve the pain. Early in 1896, the patient went to Europe, visiting Carlsbad and other re-

sorts. Two similar attacks, with severe pain, lasting about two hours, occurred during the six months he remained in Europe. He returned to America ill. There was now a good deal of indigestion, with fermentation in the digestive tract. He lost in weight and strength. He had occasional attacks of colicky pain, and usually these were associated with chill, fever, sweat, and jaundice. A very severe attack occurred two months after his return from Europe, which lasted three hours.

During the winter of 1896-7, he spent three months in the Kneipp cure of Milwaukee. During his stay there he had two attacks, accompanied with pain and jaundice. Upon leaving the Kneipp cure in the spring of 1897 he was much improved; the jaundice had disappeared; the appetite had improved, and there was a gain in weight. He was now free from attacks and was comparatively well until November, 1898, when he was suddenly seized, after a hearty dinner, with a severe colicky pain without chills. Jaundice occurred. He went to the Kneipp cure again, but received no relief. Attacks of severe pain, colicky in nature, occurred in the epigastrium and radiated in every direction, accompanied with nausea, vomiting, chill, and fever, at irregular periods, and with varying degrees of severity from that time until the present. During this interval of time he gradually lost in weight until he now weighs 125 pounds. Jaundice remained constantly present in varying degrees. He now suffers from flatulent dyspepsia, capricious appetite, constipation, and has but little strength and endurance. Occasional attacks of epigastric pain, colicky in character, occur, usually with chill and fever, followed within 24 hours by an increase of jaundice. The epigastrium is sore to the touch and to the pressure of the clothing.

Examination shows a good deal of emaciation. The skin and visible mucous membranes are deeply stained with bile; the palpable and visible arteries are rigid and tortuous. The lung-resonance on percussion and the sounds on auscultation appear normal, with the exception noted in reference to the liver and heart below. The apex beat of the heart cannot be seen or felt. The heart-dulness begins on the left at the left sternal border and extends across the sternum to the right nipple-line. The base extends along the border of the third rib, from the right mammary line to the third cartilage on the left. The heart-sounds are clear, but are heard loudest to the right of the sternum, and an accented second sound is heard in the second left interspace near the sternum. The abdomen is pendulous and flaccid. A hard, tumor-like mass is plainly felt at the costal margin at the tenth left cartilage. From this mass an organ with a sharp border can be easily felt extending to the right under the costal margin until it is lost in the back. A similar organ, with a sharp border, can be felt from the mass toward the right across the epigastrium, and ends at the ninth right costal cartilage. The whole mass, lying chiefly under the right costal margin, moves downward with inspiration. Above, on the right, percussion-dulness begins at the sixth rib, mammary line, and continues unbroken around the chest behind to the eighth rib, in front to the sternal dulness, and below to the costal margin. At the tenth left cartilage a deep notch can be felt under the edge of the mass. The lower right chest, below the sixth rib and to the right of the parasternal line, gives a tympanitic percussion-note, which extends a considerable distance below the costal margin. Palpation fails to reveal any organ under the right costal arch except the mass described as extending from the left side into the right epigastric zone. With sodium bicarbonate and tartaric acid powders, the stomach, distended with gas, occupied the right hypochondriac and epigastric regions. The colon was not distended with gas, and hence its position was not accurately noted. The urine gave a specific gravity of 1.020; contained no albumin and no sugar. Bile was present in large amount, and a few bile-stained hyalin casts were found.

A diagnosis of gallstones obstructing the gall-ducts with angiocholitis was made. *Situs viscerum inversus* was recognized in the patient for the first time. He had been examined many times by different physicians abroad and at home without this anomaly being discovered, and because of the anomaly the tumor in the left hypochondrium was mistaken for carcinoma, and by one physician acute yellow atrophy of the liver was diagnosed, because the liver could not be palpated on the right side. It was noted that the patient

was righthanded. The desperate nature of the disease was recognized and the friends were informed that surgery alone could possibly afford relief.

Dr. Christian Fenger, to whom the case was referred, concurred in the diagnosis, and on November 22, 1899, he operated at the Passavant Memorial Hospital, Chicago. The operation revealed a large stone in the cystic duct. The cystic, hepatic, and common ducts were much dilated. The anomaly of transposition of the organs was verified. The difficulty of the operation, because of the anomaly of position of the organs, and the contractions and displacements due to the long-standing disease of the gallbladder and gall-tracts will be described by Dr. Fenger in a subsequent report. The patient died of septic angiocholitis on the fourth day after operation. An autopsy was not obtained.

CASE 2.—L. S. S., aged 37, single, was a railroad engineer, whose family history was negative. He has used alcoholics very moderately; tobacco sometimes to excess. In consequence of his occupation his meals had been taken irregularly, and he has sometimes suffered from indigestion. Contracted syphilis in the winter of 1897-98. In June, 1898, he noticed a dull pain at the border of the ribs, about the right mammary line. This pain was constant when he was riding on the engine. When quiet he felt no tenderness or pain. After eating, on several occasions he had severe attacks of colicky pain, radiating from the right hypochondrium, near the tenth cartilage, downward toward the epigastrium. Jaundice accompanied these attacks of severe pain, and it never entirely left him. There was some nausea and vomiting accompanying the severe attacks. The bowels were not constipated. In July, 1898, after a somewhat severe attack of pain, he had a chill, followed by fever and sweat. These chills recurred at irregular intervals for the next two weeks, when they ceased. He was obliged to quit work and came North to Wisconsin for rest. About the 20th of September, 1898, the pains grew worse, and were associated with jaundice, chills and fever. There was slight jaundice of the conjunctiva and of the skin.

He presented himself for examination on September 29, 1899. His weight was 145 pounds, a loss of about twenty pounds from the normal. Tongue was slightly coated with a whitish fur; the lungs and heart were negative. Liver-dulness began at the level of the nipple on the right side and extended downward to the border of the ribs, where it could be felt upon deep inspiration. The edge of the liver felt more rounded, but not resistant, and was tender to the touch. A tender, round, smooth tumor extended one inch below the costal arch at the mammary line, which moved with inspiration, and was apparently attached to the liver. The urine gave a specific gravity of 1.020, contained bile, no albumin, no sugar, no blood, no casts. The blood showed 10 plasmodia of malaria, and 9,000 leukocytes per cmm.

A diagnosis of gallstones of the gallbladder and cystic duct was made with cholecystitis. Three days later Dr. Christian Fenger operated at the Mercy Hospital, Chicago. Multiple gumma of the liver was found, the largest one situated in the edge of the liver just above and behind the gallbladder. There was no obstruction of the gall-duct by pressure. The tenderness of the liver, the paroxysmal pain, and the jaundice were due entirely to the inflammation of the liver, as well as to the gumma, and probably also to the pressure upon the biliary radicles. It was noticed in operating upon this patient that his tissues were very friable. The abdominal wall, including the muscle, tore easily under the tension sutures, and it became necessary to insert the sutures far back from the edges of the wound. In spite of this precaution, the sutures tore through a part of the tissues, and a loop of intestine slipped between a couple of stitches producing obstruction of the bowels. This was relieved by opening up the wound on the third day after the operation, and the wound resutured. The patient made an uninterrupted recovery from the operation, and under the use of mercurial inunctions he became rapidly convalescent from the syphilitic lesions, and left the hospital in a good condition one month later. The patient unfortunately disappeared, and no further report of the case could be made.

Comment is unnecessary upon these two cases. In the first a careful examination of the individual enabled one easily to recognize the transposition of the viscera,

and with this anomaly in view the diagnosis of gallstones or of some disease obstructing the gall-tracts was not difficult. Without the recognition of the anomaly a diagnosis was practically impossible.

In the second case, the history of syphilis would perhaps throw some light on the case, or should perhaps awaken one's suspicions of the cause of the mass in the region of the gallbladder, and of the jaundice. However, the patient showed no syphilitic lesions of the skin or mucous membranes, and presented none of the ordinary phenomena usually found in secondary syphilis. The presence of the tumor in the region of the gallbladder, the attacks of pain, the jaundice, the chills and fever made a diagnosis of gallstones reasonable. It would perhaps have been a wise plan, inasmuch as the patient gave a history of syphilis, to have given antisyphilitic treatment before referring him to a surgeon for operation, but it did not seem possible that a mistake in diagnosis could be made in the case. Dr. Fenger, who operated upon this case, has since had a similar one, and he states that it would be practically impossible to differentiate between gumma and gallstones when the former is situated near the gallbladder or gallbladder region.

Penetrating Wounds of the Chest.—Dunn (*St. Paul Medical Journal*, September, 1900) says that the vast majority of chest-wounds, particularly in the Northwest, are those caused by pistol balls. After reviewing the literature on the subject, particularly that relating to wounds of the heart and pericardium, he discusses the treatment of chest-wounds as follows: 1. In all penetrating chest-wounds, avoid exploration, disinfect the parietal wound, and immediately apply an occlusion dressing with partial immobilization of the chest. Calm the circulation by quiet, and if necessary by opiates. Watch closely the possible supervention of internal hemorrhage and infection. 2. Intrapleural effusions of blood, though considerable, if not threatening life should not be evacuated too hastily. Time should be given for definite cessation of the hemorrhage, then it may, during the second and third weeks, be gradually removed by aseptic paracentesis. 3. In case of severe and progressive internal hemorrhage, its source, i. e., whether parietal or pulmonary, should be settled. The former should always be controlled by forceps or ligature without opening the chest, and the latter, if progressive and causing dangerous anemia, dyspnea, and disturbed cardiac action, may demand a large plastic thoracotomy and suture or tamponade of the lung parenchyma. In a certain few stab-wounds of the heart suture is practicable. 4. However, in practice it is chiefly the advent of sepsis which requires surgical interference in these injuries. When either pleura or pericardium becomes distended with infected fluid, it should be promptly opened freely and drained precisely as any other purulent pleurisy or pericarditis. [A.B.C.]

Cold as a Therapeutic Agent.—Rees (*St. Paul Medical Journal*, September, 1900) says the use of cold in the treatment of typhoid fever, appendicitis, endocarditis, pericarditis, cerebral lesions, and acute articular rheumatism is a well-recognized procedure. But its use in pneumonia is not so general. The author has used it in 7 cases of pneumonia, applying an icebag to the affected side, with satisfactory results. He quotes a number of men high in the profession who use this form of treatment for pneumonia. It tends (1) to relieve the pain; (2) to relieve the general restlessness and delirium; (3) to act as a sedative to the heart and respiration; (4) through the vasomotor mechanism to limit and relieve the congestion in the affected lung; (5) to control the general temperature. When the patient is seen early, one or more icebags should be placed over the affected area. During the preliminary stage of congestion the application should be practically continuous, though it is advised to remove the icebags for a few minutes every hour to allow the cutaneous vessels to regain their elasticity. When consolidation has set in the icebags should be continued, though their number may be reduced in most cases and they should also be removed every hour for a few minutes and the

cutaneous surface briskly rubbed with the hand. If there is no pleuritic or pericarditic pain, and there seems to be no tendency to further spread of the pneumonia into adjacent lobes, the icebags may then be transferred to the abdomen to combat a high temperature if present. The cold, if applied over the solar plexus, exerts a powerful influence in controlling temperature in this vascular area. During gray hepatization and resolution the icebag is removed and only the pneumonia jacket is worn. The contraindications to the use of cold in pneumonia are practically the same as in typhoid fever. [A.B.C.]

Varicose Veins of the Lower Extremity.—Mayo (*St. Paul Medical Journal*, September, 1900) in discussing varicose veins calls attention to the small support given the superficial veins of the leg. This deficient support offers an explanation for their frequent varicose condition. The venous coats are less liable to degenerative changes than those of the arteries. He quotes Bennett on the classification of varicose veins: (1) those which are congenital; (2) those caused by obstructed blood-current; (3) those caused by trauma, that is, those caused by strain without thrombosis; and (4) those which result from thrombosis. Varix of the leg following injury requires elastic support. The support is continued for several months and in many cases a cure will result. Elastic support is seldom of benefit extending above the knee. The supporting treatment is used with benefit in many patients who do not lead active lives and are able to give time and attention to prevent an increase of the disease. There are many methods of curing ulcer, the essential features of which are cleansing and rest in bed or support by bandage. The sloughing ulcers with edema and of foul odor may be readily cleansed by applying one or more yeast poultices. Kohler grafts ulcers by the Thiersch method without removing granulations but it is more satisfactory to excise the ulcer and remove the fibrous base which, if left, later impairs the vitality of the graft, then a Thiersch or Wolf graft may be applied with good prospect of success. Schede's operation may prove beneficial, but should the deeper veins be thrombosed and varicosed the operation may cause gangrene by cutting off the return circulation from the foot. [A.B.C.]

Cured Spina Bifida.—John Lindsay (*Glasgow Medical Journal*, September, 1900), after an interval of 5½ years presents a case of spina bifida or sacral teratoma undergoing spontaneous cure. The child was born June 24, 1894. Over the lower lumbar and upper sacral regions, lying chiefly to the right of the middle line, there was a considerable swelling of an oval shape, the skin-covering of which was normal in character, except for a capillary nevus on its left lateral surface. The tumor, to palpation, appeared to consist of fat. From near its lower end there projected a button like protuberance, with a constricted neck and enlarged cup-shaped head. The hollow of the cup was filled with what looked like granulations, but their surface was dry and glazed; and from the center of this bright-red area there hung down an appendage about 3 inches long, slender at its origin, but widening out to a bulbous extremity. In color and consistence it was exactly like the umbilical cord, and seemed to consist of a gelatinous substance in a thin investment. An elastic sac, tensely filled with fluid, gives much the same impression to the touch, but no fluctuation was detected. The appendage was dressed with a piece of linen in the same manner as the stump of the funis. Next morning it had shrivelled, and eventually it dropped off about the same time as the remains of the cord—that is, about the fourth or fifth day. Lindsay thought there had been a spinal meningocele; the skin over it had ruptured, and, the edges of the tear granulating, had cut off the extruded portion of the sac. Lindsay has no doubt that the infant was a subject of spina bifida, although no deformity of spine could be detected by palpation. The frequency of the condition in the lumbosacral region and the presence of a large nevus made its occurrence probable. He admits the possibility of the tumor showing imperfect development of one of pygopus twins, but says that this is mere speculation. He also thinks from the manner of cure that this may have been another umbilical cord and concludes with the statement that if the decision is to be given on the probabilities he would say it was a case of cured spina bifida, but if upon the evidence of touch and sight he would conclude it was an umbilical cord. [G.C.C.H.]

The Control of Tuberculosis.—Evidence is not wanting of increase in popular knowledge of the communicability of tuberculosis and of a more general appreciation of the corollary that restriction of the disease depends in large measure upon control of the disease products. In combating the assertion that tuberculosis is becoming more common at high altitudes, where the air is pure and rare, the *Philadelphia Record* points out that this is to be attributed to the increasing opportunities for communication in consequence of the growing number of patients that congregate in such places. Statistics show that while in 1886 there were in New York City 440 deaths from tuberculosis, in 1890 the number was 397; in 1894, 316; in 1897, 295. In England and Wales the death-rate from tuberculosis has been reduced from 38 per 10,000 of population in 1838 to about 13 per 10,000 at the present day. The *Record*, further, supports the recommendations that tuberculous cattle should be killed and the sputa of tuberculous patients rendered sterile. Although regulations as to cattle exist in 20 States, they are rigidly enforced only in two, namely, New York and Massachusetts, and in these two there has been a steady decrease in the number of tuberculous patients. In the opinion of the *Record* it is necessary for Congress to enact legislation preventing the shipment of tuberculous cattle from one State to another, and laws should be passed requiring the inspection of dairies by competent veterinarians. Tuberculous patients should be instructed to burn their sputa, and the careless, the indifferent, and the ignorant should be subjected to the authority of health officials. Only by such rational measures, radical and arbitrary as they may seem, can further restriction of tuberculosis be hoped for, although personal and civic hygiene of a general character are not to be ignored. One of the noteworthy advances for which the twentieth century promises to be distinguished is the practical suppression of tuberculosis.

The Grand Jury and the Whipping Post.—A Pennsylvania judge recently expressed the opinion that the grand jury should be abolished. In his judgment the grand inquest is antiquated and useless. But now, right in the face of this grave indictment, comes a Philadelphia grand jury recommending that the whipping-post be established in this city. Can anyone say hence-

forth that the grand jury is a useless institution? This particular grand jury has had its ire aroused by the drunken wife-beaters of Philadelphia and would send all these brutes to the whipping-post. An eye for an eye, a tooth for a tooth, and a flogging for a beating, is about the right measure of justice according to the grand jury. This distinguished tribunal, however, does not specify where the town whipping-post should be set up, but we suppose at some point where the greatest crowds could be attracted. There might be a Court, not of Honor, but of Dishonor, erected on Broad Street, with seats for spectators. This would far excel in interest a Roman circus, a Spanish bull-fight, or even an American prize-fight. A few pillories and stocks might be added for the sake of variety, and a few murderers in cages, after the custom observed in China, might be put on exhibition for the benefit of small boys. The grand jury's sympathies for the victims of drunken husbands do it great honor. This city already has too many wife-beaters. But the grand jurymen have allowed their hearts to get the better of their heads. No mere atrocity of crime can justify an atrocity of punishment. Moreover, medievalism is past. Whether in thought, in literature, in architecture, or in the punishment of criminals, we should no longer resort to the customs of the middle ages. Even the grand jury itself is a relic of the past, and, as we have already said, it might as well, in the opinion of a learned judge, be abolished.

Wine, Beer, and Whisky Consumption of the Most Important Countries.—The *Allgemeine Zeitung* of July 19, 1900, publishes the following statistics regarding the per capita consumption of alcoholic beverages in different countries for the years 1898 and 1897:

PER CAPITA CONSUMPTION IN LITERS.

	WINE.		BEER.		WHISKY.	
	1898.	1897.	1898.	1897.	1898.	1897.
Great Britain	1.9	1.8	141.9	142.7	4.7	4.6
Germany	3.5	6.1	123.0	116.0	8.4	8.6
France	112.0	111.0	25.0	24.0	9.4	8.6
Russia			4.1	4.3	4.9	4.9
Austro-Hungary		12.0		45.0		10.0
Switzerland	67.0	71.0	67.0	70.0	6.2	6.2
Netherlands					8.2	8.5

Denmark			94.5	91.5	15.0	14.5
Belgium			207.0	202.0	8.7	9.1
United States	1.0	2.0	59.1	55.4	4.2	3.8

These figures are only approximate, of course, but they are nevertheless suggestive and in some instances

surprising. For example, one would expect the ratio of beer to whisky consumption to be much larger in Germany (about 15:1) than it actually is. The figures for the United States, when compared with those of other countries, impress one as fairly accurate—the whisky and beer consumption hold a relation of about 1:14.

Life-Insurance Fees.—A correspondent asks us whether a physician should allow the life-insurance companies to force him to accept a fee of less than five dollars for each medical examination, and even to exact from him without additional compensation a second examination of the urine. If this were merely a question of let or hindrance, we should unqualifiedly say that no physician should submit to such terms. Unfortunately it is a private matter between the individual company and the individual physician, and we do not see how a general rule can be made applicable. Each party to the contract is a free agent, and if the terms do not suit them both, one of them may withdraw. No physician is obliged to work for a fee that does not satisfy him, and no corporation is obliged to give more than it can bargain for. In other words, this is simply another phase of the sempiternal question of capital and labor—a question that will not stay down so long as the laborer is worthy of his hire and corporations continue to have no souls. In the coal regions of Pennsylvania at present we see this conflict in its bitterest extreme—but the law of political economy permeates everywhere, and the medical profession is not exempt from its workings. The remedy offered in trades-unionism is not always an effective one, and experience shows that trades-unionism in medicine especially is not popular or successful. Let each physician value his own services at the highest, but he must also see to it that they are worth what he asks for them. The life-insurance companies are, as a rule, shrewd enough to see that it is for their best interests to secure the best medical opinion. If they do not do so, they are likely to suffer eventually for their stinginess, and to pay for more dead men than suits their purse.

Hand Disinfection.—From the time when aseptic surgery began its mission of saving life and quelling pain, the surgeon has striven to accomplish an impossibility, namely, to discover a method of cleansing his hands which will always, and without fail, render them absolutely sterile. As shown by Welch, it is impossible to remove every bacterium from the skin, even by the most severe methods of disinfection, and chiefly because of the presence of the *Staphylococcus epidermidis albus*, which inhabits the deeper portions of the gland-crypts. After the best of antiseptic methods, a bit of skin may be excised, and the presence of this germ proved therein. Recently, the subject of hand-disin-

fection has been revived in Germany, and numbers of articles have been written by different enthusiasts making all sorts of claims for all sorts of methods. Notably among some of the eccentricities may be mentioned the hot-water and alcohol scheme of Ahlfeld, the brush, water and soap of Schleich, and Mikulicz's tincture of soap. In the *Archiv für klinische Chirurgie* (Band 61, p. 554), Vollbrecht suggests the use of a solid mixture of alcohol and soap, for which he claims all the advantages of the fluid-tinctures of Mikulicz and Furbringer, but which, being in a solid form, does not possess many of their disadvantages. In the same number of the *Archiv*, p. 463, Sarwey gives the results of an elaborate series of experiments which he and Th. Paul had carried out, and have published in the late numbers of the *Münchener medizinische Wochenschrift*. In this article is clearly shown the impossibility of rendering the hands sterile by methods in which there is no use made of a strong and vigorous antiseptic, though the germs may be greatly reduced in number by thorough washing. In the *Münchener medizinische Wochenschrift* for July 24 of this year, Krönig and Blumberg publish conclusions, based on a somewhat extensive research, in which they also demonstrate the fallacy of methods in which no strong germicide is used. But most of this literature is largely a mass of contradiction, each man finding and pointing out the errors of somebody else's work, but, with a remarkable amount of the strabismus of conceit, failing to perceive that perhaps his own vision is not perfect. The one thought which may be safely garnered from it, is that there has not yet been discovered any method of disinfecting the hands which is entirely satisfactory. This is further substantiated by the fact that the members of the surgical profession practise so many different methods and modifications of cleansing their hands that these may be truly called legion. And the surgeons of this day are beginning to recognize this fact, and in the sincerity of their endeavor have made a great stride in the advance of aseptic technic, namely, the use of rubber gloves.

Surgical Treatment of Trigeminal Neuralgia.—Although severe cases of facial neuralgia have been successfully treated by removal of the Gasserian ganglion for a number of years, the operation until now has been practised by comparatively few surgeons and some have doubted the advisability of the operation. Probably no one has done more for the advancement of the surgery of the nervous system than Victor Horsley, and an article from his pen in the *Practitioner* for September, 1900, on this subject seems deserving of special notice. Mr. Horsley reports having performed the operation for removal of the Gasserian ganglion 21 times. He advocates the operation only in very severe neuralgias of paroxysmal character limited to one side of the face. These neuralgias very often begin with one branch or division of the fifth nerve, only

later gradually invading other branches. They are frequently accompanied by other evidence of nerve-stimulation, such as secretion of tears, saliva, and vasomotor dilation of the vessels of the conjunctiva, and often also of the vessels of the face. Only in the latest stages is it accompanied by any anesthesia. With regard to the pathology of such neuralgias, he believes that they begin in the peripheral branches of the fifth nerve and then gradually, like all neurites, creep as an inflammatory process up the peripheral branches of the nerve until they arrive at the Gasserian ganglion. He gives a very thorough study of the anatomic conditions concerned, for which we can hardly find space in these columns. Hartley, in America, and Krause, in Germany, are given the credit of having independently devised the operation which Mr. Horsley considers the best, and which he designates as the Krause-Hartley method. In performing the operation Mr. Horsley does not employ Wagner's osteoplastic flap, but removes the bone altogether. The temperosphenoidal lobe is then pulled upward by a strong retractor until the floor of the skull can be seen with the foramina through which the nerve branches escape. He considers hemorrhage the source of the greatest difficulty in these operations. This may arise either from injury of the cavernous sinus emissary veins which cross the ganglion and go out of the skull through the foramen ovale and also to a less degree through the foramen rotundum, or from a rupture of one of the lateral branches of the basilar artery, these branches being sometimes of considerable size. Both of these sources of hemorrhage can be controlled by suitable pressure with long probes. After the ganglion has been freed and the divisions cut loose at the foramina through which they escape, it is seized and drawn upon, thus separating it from its attachment to the pons. Another difficulty is that the ophthalmic division which runs on the upper and outer wall of the cavernous sinus may be unseen and left behind. If the usual precautions are taken with regard to asepsis there is little risk to life from the operation itself. Out of 21 operations Mr. Horsley has had two deaths, the first in a man of 62, who died two months after the operation, from staphylococcus infection. This was quite likely contracted from an extensive syphilitic ulceration in the nose which existed at the time of operation. The other fatal case occurred in a woman of 82 years, who recovered from the operation without symptoms of shock, but a few hours after was taken with signs of apoplexy. She lived two days after operation. At the necropsy a small hemorrhage into the pons was the only source of death which could be discovered. This was no doubt caused by separation of the sensory root. Mr. Horsley has operated upon four patients over 80 years of age and does not consider age itself as necessarily a contraindication to the operation. He advises special care as to the preparation for the operation. For two days before operation the

eye of that side is washed out several times a day with boric-acid solution and the ear is cleansed with carbolic solution and boric-acid powder. The side of the head should be shaved and very carefully prepared. He advocates the use of a drainage-tube, which should be removed as far from the ear as possible. Loss of the eye is another possible danger of the operation. This resulted in one of his patients, but since adopting the following treatment Mr. Horsley has not seen trouble with the eye: The eyelids are stitched together temporarily with horse hair, the stitches being taken out at the end of the operation. This prevents the vapor of the anesthetic or any antiseptic solution getting into the eye by accident. After the operation a sheet of guttapercha tissue is fastened in a line above the outer canthus of the eye and covers the dressing so that no antiseptic can get forward to irritate the conjunctiva. In the case of the patient who lost the eye Mr. Horsley attributes the trouble to the contact of the antiseptics with the conjunctiva. As to the permanent results of the operation he has seen no recurrence of pain in any of his patients. This coincides with Krause's experience and that of many others.

These successful results reported by Mr. Horsley and those of many others by other prominent surgeons seem to indicate that the operation has been accorded a recognized place in brain surgery. Up to this date we have noticed reports of 109 operations by various surgeons in America, with very satisfactory results in most cases. The operation offers the only permanent relief in this extremely painful affection, and if properly performed there can be no doubt that the relief will be permanent. While not an operation of very great gravity in the hands of skilful surgeons it should not be undertaken by any one without a thorough knowledge of surgery and the anatomy of the parts involved, and practice on the cadaver should in every case precede operations on the living subject.

The Role of the Mosquito in the Etiology of Malarial Fever.—Those who sneer at science and scientific methods will find little satisfaction in the results of the experiments that have recently been undertaken for the purpose of absolutely confirming current theories as to the role played by mosquitos in the conveyance of the malarial fevers. Too full meed of praise cannot be bestowed upon the English investigators in India and the host of colleagues in other countries who have contributed to this important phase of knowledge. The first great step was made when Laveran discovered the plasmodium malariae, and his observations were at once authenticated and amplified by those of Italian, American, and Russian investigators. Then followed the announcement of Manson that the mosquito served as the intermediate host for the parasite and the medium for its transmission to man, and convincing evidence in support of the validity of this proposition was soon

furnished by Ross and others. For the purpose of making the demonstration complete and conclusive, two members of the staff of the London School of Tropical Medicine, Drs. Sambon and Low, went in the month of June to one of the most intensely malarial localities in Italy, where they have since lived in a wooden hut protected from the invasion of mosquitos only by mosquito-netting and wire screens in doors and windows. No antiperiodic drug whatever was employed, and the experimenters went about by day, but remained scrupulously within doors between sunset and sunrise. None of the party has suffered from malarial fever, despite the fact of their paludal surroundings and the general prevalence of the disease in those all about them. An analogous experience is reported by Dr. Elliott, a member of an expedition sent from Liverpool to West Africa, who relates that despite exposure for four months in intensely malarial localities, without the employment of any other prophylactic measure than the use of mosquito-nets, all of the members of the party remained perfectly well.

In the *British Medical Journal* for September 29, 1900, p. 949, Manson reports the successful inoculation in London with malaria of an uninfected individual by means of infected mosquitos brought from Italy, all of the details of the observation being carried out with scrupulous exactness and control. Dr. Manson's son, a healthy man, 23 years old, who had not resided in a malarial locality since childhood, volunteered as a subject for the experiment and submitted on three occasions to the bites of the imported and infected mosquitos, with the result that within a few days of the third inoculation characteristic symptoms of tertian malarial fever appeared, together with the presence of the corresponding parasites in the blood. Relief was promptly afforded by the administration of quinin. Similar observations are said to have been made in New York on a patient in Bellevue Hospital, who volunteered for the purposes of the experiment.

If any doubts have remained in the minds of informed individuals as to the part played by the mosquito in the conveyance of malaria the observations here recorded must remove the last vestige. It is, of course, not implied that there may not be other media of transmission, as, for instance, the water, but for the present at least it can be considered as demonstrated that the mosquito (*anopheles*) serves as the intermediate host for the malarial parasite. With this knowledge the indications are as clear as the certainty with which night follows day, namely: avoidance of malarial localities, destruction of the breeding-pools of *anopheles*, and protection from mosquito-bites.

Suggestions, to Writers, No. 62. Concerning Emphasis, Underlining, Stress, etc.—In an ordinary English sentence almost any single word may be chosen for emphasis, according to the meaning which

the speaker wishes to convey. As it is almost impossible, except by circumlocution, to give the sentence the exact shade of meaning desired without this emphasis, we see that emphasizing a word is an important and almost a necessary part of the function of language. We smile at the Chinese who convey wholly different ideas by the same sound through utterance in higher or lower keys or pitches—and yet by similar means, rising or falling inflections, intensity, rapidity, emphasis, etc., we ourselves carry out the same purpose. Take the sentence: *I commanded him to go.*

This may be spoken in four ways:

I commanded him to go;

I commanded him to go;

I commanded him to go;

I commanded him to go;

with four distinctly different meanings.

If instead of a period we place an interrogation mark after each we add four meanings, and if instead of an interrogation mark we add an exclamation point we have four other indications. As the unemphasized sentence differs in meaning from all the others, we thus have at least 13 clearly defined significances expressed by emphasis and inflection. This leaves out of the count other shades expressible by stress upon words, and also ignores a hundred nuances obtained by inflection, action, gesture, etc. A good actor can express a dozen or two shades of meaning by differences of enunciation of a monosyllable such as *yes* or *no*, which the printed word cannot indicate. Function, life, physiology, is thus added to the dead printed sentence, giving it a living and ever-varying phase to indicate or to keep up with which the mechanic and uniform printed forms make no attempt. The imagination of the silent reader must supply the thousandfold life-elements of the speaker, actor, elocutionist, singer, etc. To one endowed with imagination his printed form is only the crude suggester of a thought and meaning, just as ether-waves are the brute beginners, or material, which suggest the infinitely rich product of vision. One smiles at the antics and tricks of formalists and the unimaginative to express themselves by signs, accents, diacritics, hyphens, italics, and underlinings. Nothing is more ludicrous than a printed page full of words or sentences in italics, small caps, and large caps, whereby the author, in default of training or of ability to make himself understood by words as usually printed and spoken, makes up for his deficiencies by excess of force, and bawls and howls with thwacking gesture and larynx-splitting tones. The less thought a speaker has and the less he is able to express it in ordinary tones of voice, the more is he inclined to scream and roar. So it is in writing. Varying sizes and styles of type, italics, and capitals should not be used for emphasis or to lay stress upon what are deemed matters of prime importance, but solely to indicate quotations, headings, titles, case-histories, foot-notes, references, etc.

An important corollary of the inadequacy of the printed form to express all but the mere rudiments and essentials of thought and feeling, is that it cannot express phonation except in an utterly inadequate way and even then only temporarily. Sounds of letters and syllables are different in different parts of the same country and State, and are never the same anywhere for but a short time. But the uttered sound is the living thing, and will always be the master and leader. Soon or late to some approximate conformity the printed form must change or it must die. The modern printing office is a huge and complex thing with its hundreds of fonts of type, and the complexity is a great tax on education and civilization. Every hyphen, dieresis, accent, or diacritic mark we can spare lessens that expense and saves future expense and labor in dropping it when it is finally recognized as not only useless but misleading. The hyphen or dieresis is no more necessary in *infraabdominal*, *cooperation*, *zoology*, *oophorectomy*, etc., to separate the vowels or sounds, than it is in *innuendo*, *naive*, *diiodoform*, *biannual*, *dielectric*, *abiogenesis*, *coincide*, and hundreds of words in which separately-pronounced vowels follow without a consonant. If a boy is so stupid as to say *koop'-eration* and *zool'-o-je* no hyphens or diereses will help him. Is a dieresis needed to avoid the pronunciation of *reaction* as a two-syllabled word? A pupil must learn without markings that *coin* is a monosyllable, but that *coincident* has four syllables; that *coeliac* is not pronounced *ko-ell'-yak* nor coefficient *ke-fis'-i-ent*. Diacritic marks cannot teach pronunciation.

Early Diagnosis of Pulmonary Tuberculosis.—Bell (*St. Paul Medical Journal*, September, 1900) emphasizes the importance of obtaining a complete personal and family history of the patient suspected of having tuberculosis. Anal fistula or ischio-rectal abscess should excite suspicion. Clinically tuberculous patients may be separated into 3 classes: First a class presenting the symptoms of causeless dyspepsia, gradual loss of flesh, inability to bear exertion, accelerated pulse, slight afternoon rise of temperature, pale or sallow skin, slight cough; later positive physical signs and microscopic evidence of infection. Second a class consisting largely of young females presenting at first the symptoms of slight but progressive anemia, loss of flesh and strength, breathlessness on slight exertion, slight elevation of temperature, pulse small, increased in frequency and the arterial tension higher than in cases of primary anemia of the same grade; later cough, free expectoration, night-sweats and all the classic symptoms of pulmonary tuberculosis. Third a not inconsiderable class where the first warning is a hemorrhage or a series of slight hemorrhages without provocation in an individual apparently in perfect health, followed in a large percentage of cases by increased pulse-rate, considerable elevation of temperature and all the other evidences of tuberculous infection. The author says in his experience a dry, harsh, lusterless condition of the hair is of diagnostic value in relation to tuberculosis. Continuous dilation of the pupils, occasionally one more than the other, is a frequent early sign of this disease. A general discussion of the findings on inspection, palpation, percussion, auscultation, thermometry, etc., are discussed. He says of the newer diagnostic methods none give more promise than the **serum method** of diagnosis. Arolin and Courmont claim as high as 100% of reactions in cases known to be tuberculosis. [A.B.C.]

Reviews.

The Transactions of the Medical Society of the State of California. Thirtieth Annual Session San Francisco, April, 1900. Vol 30, 8vo, pp. xvii, 619. Published by the Society.

This volume makes a most creditable publication containing about 50 papers on subjects in the various departments of medicine by active practitioners. Not the least commendable feature of the transactions is the promptitude with which it has been published. The mechanical execution and the illustrations of the work are eminently satisfactory.

The Pocket Formulary for the Treatment of Disease in Children. By LUDWIG FREYBERGER, M.D., of London. Second Edition. London: Rebman, Limited, 1900.

On account of the many changes and additions in the new British Pharmacopeia, it has been deemed necessary to practically rewrite this valuable little formulary. We have already spoken favorably of the first edition of the work, and we heartily commend it in its revised form as a concise and handy compend of information relative to the treatment of diseases of children by drugs.

International Clinics. Edited by HENRY W. CATTELL, M.D. Vol. II. Tenth series, 1900. 8vo, pp. x, 300. Philadelphia: J. B. Lippincott Co.

Every practitioner will be sure to find something interesting in the 31 articles contained in the volume before us. A large number of subjects are considered from various aspects, but always in an essentially practical and clinical manner. There is no dearth, as there is no superfluity of illustrations. The colored plate, depicting kromoscopic images, is especially well executed, and the description of the apparatus and the principles that underlie its mechanism is most timely.

Beneath Hawaiian Palms and Stars. By E. S. GOOD-
NUE, Government Physician; Medical Superintendent
Malulain Government Hospital. Pp. xv, 248. Cincinnati: The Editor Publishing Co., 1900. Price, \$1.50.

This is one of three books written as the result of observations made in the course of a residence of several years in the Hawaiian Islands and describes various conditions and phases of life in these new American possessions. The influences that led to the change in government are briefly considered, and numerous facts with regard to the geographical situation of the islands, their natural resources, the character of their inhabitants, their occupations and their diseases, and the opportunities for strangers, are detailed.

Diseases of the Eye. By EDWARD NETTLESHIP, F.R.C.S. Revised and Edited by Wm. Campbell Posey, A.B., M.D. Sixth American Edition from the Sixth English Edition. With a Supplement on Examinations for Color-Blindness, and Vision and Hearing, by William Thomson, M.D. Philadelphia and New York: Lea Bros. & Co., 1900.

An extensive review of this well-known and valuable manual is unnecessary at this late date. A work that has passed through six editions needs little else to commend its practical value. On account of certain points of divergence in the views and methods of English and American ophthalmologists, the publishers have secured the services of Dr. W. C. Posey, of Philadelphia, to revise the book to conform to the best American practice, and to add descriptions of the new forms of ocular disease and of bacteria recently identified with conjunctival inflammation.

In the main, the editor has performed his task very satisfactorily, but we can hardly agree that an ophthalmic work, in which there is no mention of uncorrected ametropia or muscle-defect in the paragraphs relating to blepharitis and

chronic conjunctivitis, constitutes a "thoroughly up-to-date American text book."

Printed on thick paper, the new book is much more bulky in appearance than the previous edition, although it contains but 32 more pages, some of which are occupied by new illustrations.

Transactions of the Louisiana State Medical Society. Twenty-first Annual Session held at New Orleans, La., April 19, 20, 21, 1900.

This volume does credit to the good scientific ability and workmanship of the members of the Louisiana State Society. Among many noteworthy papers is that of Dr. Matas upon the "Growing Importance and Value of Local and Regional Anesthesia in Minor and Major Surgery." We know of no epitome of this subject that is so complete and trustworthy, and is of that remarkable excellence which the author has taught us to find in his work.

Essentials of Medical and Clinical Chemistry with Laboratory Exercises. By SAMUEL WOODY, M.D. Fourth Edition, Revised and Enlarged. Illustrated. 8vo, pp. 243. Philadelphia: P. Blakiston's Son & Co., 1900. Price, \$1.50 net.

This little manual contains a large amount of information that should render it especially useful to the medical student in his laboratory work. The text is written in a clear and interesting manner and the illustrations suffice to serve their purpose. The work is arranged into three parts, the major portion being devoted to the first, organic chemistry, and the remainder divided about equally between the second and third parts, organic chemistry, and clinical chemistry. The present edition has been carefully revised and much new matter has been added.

A Short Practice of Gynecology. By HENRY JELLET, B.A., M.D., B.Ch., B.A.O. (Dublin University), F.R.C.P.I., L.M.; University Examiner in Midwifery and Gynecology, Dublin University. With 125 illustrations. London: J. & A. Churchill; Philadelphia: P. Blakiston's Sons & Co.

In a little volume of 400 pages the author gives a concise account of gynecologic diseases and their treatment. No effort has been made to describe all accepted theories, modes of treatment and operations; and only those theories and practices which appear to rest on the surest basis in the present state of gynecologic knowledge have been presented. In its essentials the practice taught in this book is that employed in the Rotunda Hospital, Dublin, with which the author was formerly connected. One hundred and twenty-five illustrations and diagrams so necessary to a manual on this subject are introduced and add much to the value of the book.

A Manual of Clinical Diagnosis by Means of Microscopic and Chemical Methods for Students, Hospital Physicians and Practitioners. By CHARLES E. SIMON, M.D., late Assistant Resident Physician of Johns Hopkins Hospital, Third edition. Thoroughly revised. Illustrated with 136 engravings and 18 plates in colors. 8vo, pp. 558. Philadelphia and New York: Lea Brothers & Co. 1900.

This admirable volume has attained deserved success and the appreciation in which it is held is indicated by the exhaustion of two editions in four years. The last few years have witnessed a marked advance in methods of clinical diagnosis and a powerful impetus has been given to the establishment of laboratories for the pursuit of that subject, so that the book before us fills a need, which, to speak paradoxically, it has contributed to create. Medicine is progressively growing away from the merely empiric and tending toward the exact and the scientific; treatment has in some degree been subordinated to prophylaxis; and diagnosis is receiving constantly increasing attention. Into this vortex all medical men have been swept, undergraduate, postgrad-

uate, generalist, specialist. The apparatus required is, as a rule, not elaborate or expensive, the laboratory's needs not excessively large; but what is absolutely essential is technical knowledge and the investigation habit. Energy is expended in the direction of least resistance, and training and application are required that the proper direction for this expenditure is given. It remains only to be added that the volume under review is not less excellent in execution than in conception. In the 13 chapters into which it is divided it deals successively with the following subjects: Blood, Secretions of the Mouth, Gastric Juice and Gastric Conduits, Feces, Nasal Secretions, Sputum, Urine, Transudates and Exudates, Cystic Contents, Cerebrospinal Fluid, Semen, Vaginal Discharge, Secretion of the Mammary Glands.

A Manual of Obstetrics. By A. F. A. KINO, M.D., Professor of Obstetrics and Diseases of Women in the Medical Department of the Columbian University, Washington, D. C., and in the University of Vermont, etc. In one 12mo volume of 612 pages, with 264 illustrations. Philadelphia and New York: Lea Brothers & Co. Cloth, \$2.50, net.

Dr. King's manual fulfils in every particular its chief purpose, being a book of convenient size which presents, in an easily intelligible form, such an outline of the rudiments and essentials of obstetric science as may constitute a good groundwork for the student at the beginning of his obstetric studies, and one by which he is better prepared to understand and assimilate the extensive knowledge and classical descriptions contained in the larger and more elaborate textbooks. That the manual has proved of marked utility is evidenced by the fact that the eighth edition is now presented. Although there have not been many additions, yet the work has been modified in conformity with the progressive trend of obstetric thought; omissions have been supplied; errors corrected; and the text has been embellished with 41 additional engravings. Attention is called to the 3 new remedies which have been employed in the treatment of puerperal septicemia: (1) nuclein; (2) hypodermoclysis of normal salt-solution; (3) antistreptococcic serum. Nuclein is supposed to increase the number of leukocytes in the blood, thus promoting phagocytosis; in addition it is considered to increase the antitoxic and germicidal properties of the blood-serum. The author believes that although its individual value as a curative agent cannot be definitely stated, yet there is sufficient evidence of its good effects to warrant its employment. The value of saline solution is undoubted. He considers that further experience is needed to demonstrate the superiority of serumtherapy, and thinks it is not justifiable at present to use the serum alone to the exclusion of other remedies. The other methods should be used conjointly. Ether is considered as the preferable anesthetic in labor because of its safety. The author also believes that it is less liable than chloroform to lessen the force of uterine contractions. The work of the publisher has been well done, printing and paper are good, and we can thoroughly recommend this work to the student and practitioner.

Normal Histology. By EDWARD K. DUNHAM, M.D., Professor of General Pathology, Bacteriology, and Hygiene, in the University and Bellevue Hospital Medical College, New York. New (2d) edition. 8vo, pp. 319; 244 illustrations. Philadelphia and New York: Lea Brothers & Co. Cloth, \$2.50, net.

The author's postulate on the study of normal histology is summed up in the beginning of the introductory chapter, where he urges upon the student the importance of "habitually associating his ideas of structure and functional activity, until he can hardly think of what a structure is without at once recalling what it *does*." He also says that "to the conception of the body during health," which the student "has formed by this thoughtful method, he must then add a conception of the influence exerted, both on the structure and activities of the body, by abnormal conditions which disturb or thwart the usual working of that complex mechanism." Notwithstanding these statements the reader

often may forget that it is neither a work on physiology nor on pathology which he peruses, so much is said of function, normal and perverted, relatively so little of form *per se*.

Eminent authority can be named in support of this method of presenting the subject to students of medicine, not merely, according to the author, as a time-saving device, but, what is more important, as a corrective of spendthrift outlay of nerve-force. However, the morphologist may raise the question whether more is not saved in time and effort, and gained in acquisition, by simple concentration of attention on the subject, than by the method of association of ideas. Logically, knowledge of anatomy must precede study of physiology and of pathology (so also says the author) and more accurate knowledge of structure might occasionally avert complex theories of function with great advantage to the overworked student.

This book is arranged on the plan long familiar in other and older textbooks on histology and in this respect does not outdo them in merit, the author being at his best in his excursions into the provinces of physiology and pathology.

It is with some surprise that one finds the teeth described in the chapter on the skin, which is squarely against the author's theory of "logical correlation," and one cannot but wish that this same theory had led him to classify the organs and of course conformably.

The last chapter of the book is entitled "Histological Technique," which among other technical matters contains lucid instructions for making microscopic measurements, and this naturally directs attention to the omission of the magnification of all the—not original, but in the main well-chosen—illustrations accompanying the text.

Typographically, the volume is very attractive, and doubtless it will well serve the purpose for which it has been specially designed.

Medical Diagnosis, with Special Reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. DaCosta, M.D., LL.D., Physician to the Pennsylvania Hospital, etc. Ninth Edition, Revised. Pp. 966. Philadelphia: J. B. Lippincott Co

The appearance of another edition of this world-famed book, revised by the author himself, now more than a generation after the first edition was offered to the profession, is the occasion for mutual congratulation. The profession is fortunate in thus securing the benefit of ripe experience; while the author is privileged to see the fruit of his labors, not only in his own city, where he labored so faithfully and with such signal success, but also in the country at large, and even in foreign lands where his book is now a standard text in four languages.

The continued popularity of this work is due to the same causes which kept its author at the head of the profession in practice; a wide and thorough knowledge of the art and science of medicine, and a readiness at all times to prove each new departure and then accept it when its value was evident. This has been possible by reason of his adherence to the dictum laid down by himself in a recent address: "The life of a physician must be always the life of an observer and a thinker." The book itself is an admirable specimen of the publisher's art. Its form and size of page are more convenient than those of the last edition. Its type and printing are better fitted for perusal. The illustrations also reflect the general advance in bookmaking. The indexing has been amplified, which always adds to the value of a book intended for busy men.

The general clinical classification has not been changed since the first edition was issued 36 years ago. Time has demonstrated its correctness. A few special changes in classification are evident. The list of continued fevers is increased by the addition of plague, glanders, and Malta fever; while to it have also been transferred yellow fever, from periodic; and dengue from eruptive fevers. Typhomalarial fever is added, and fully discussed, under the heading of periodic fevers. This, however, the author points out is not a single disease, but a double infection. Malaritypo is suggested as a more fitting term for it.

In the section devoted to diseases of the blood, the latest clinical methods and microscopic findings are introduced.

The important subject of leucocytosis is discussed in its general and special relations.

Throughout the book bacteriologic methods and findings have been duly recognized.

Colored plates are introduced to illustrate the subjects of skiagraphy, blood changes, and malarial organisms.

A general survey of the book shows an adherence to old and tried lines, and shows the object of revision to be an effort at refining rather than amplifying. This edition cannot fail to enjoy even a greater popularity than its predecessors.

Practical Gynecology: A Comprehensive Text-book for Students and Physicians. By E. E. MONTGOMERY, M.D., Professor of Gynecology, Jefferson Medical College; Gynecologist to Jefferson Medical College and St. Joseph's Hospitals; Consulting Gynecologist to the Philadelphia Lying-in Charity. Containing 819 pages and 527 illustrations. Philadelphia: P. Blakiston's Sons & Co. Price, \$5.00.

In this day of multiplicity of textbooks on every subject, a new work must possess unusual merit to win for itself recognition and admission to the library of the busy practitioner; but we prophesy for this work a welcome reception, and a warm place in the estimation of both physicians and students, because it possesses those qualities which recommend it to busy men who want clear-cut, lucid and concise teaching, free from superfluities and theorizations which burden the mind without enlightening it. The rich experience of the author, both as teacher and surgeon, enables him to present the valuable and essential without a mass of useless verbiage or a cloud of speculative hypothesis. In this treatise there is no mere multiplication of words without knowledge; for the writer does not consider that "our felicity and happiness lie in superfluities, but rather in necessary things." The mature judgment has been exercised, and an American work for American physicians is offered to his conferees with the modest hope that it may be "the means of lightening the work of the student, of making more clear the pathway of the busy practitioner, and most of all, of benefiting suffering women through improved methods of diagnosis and treatment." The effort has been made to present a comprehensive treatise upon gynecology, giving the experience and methods of the most careful men, and to indicate which in the author's experience have been found most useful and worthy of acceptance. Each subject is considered with reference to its influence upon the entire genital tract, and the book is divided into sections rather than chapters. The plan of arrangement is unique and enables the student to study consecutively the inflammatory processes, neoplasms, or malformations of different portions of the genital apparatus, the practical or clinical rather than the anatomic classification being used. The author has found by experience that this arrangement is most effective in impressing the subject upon the student, and believes it will be preferable to one who uses the work merely to refresh his mind on any particular division of the specialty. By the employment of this classification, injuries of the perineum and cervix, as well as vaginal fistulas, are included under the section on "malformations" and denominated as acquired malformations. The plan of the book is thus: After an introduction dealing with the theories, foundation, and purpose of gynecology the following subjects are successively treated: (1) Diagnosis; (2) pelvic examination; (3) abdominal examination; (4) therapeutics: (a) medical treatment; (b) local therapeutics, and (c) electricity; (5) anatomy of the genitalia; (6) physiology of the sexual organs; (7) malformations; (8) inflammation of genital tract; (9) deviations of the pelvic organs; (10) genitourinary hemorrhage and ectopic gestation; and, lastly, genital tumors. A 12 page table of contents together with a comprehensive index of 30 pages, make the work especially useful as a book of reference. It is embellished with 527 illustrations, nearly all of which have been drawn and engraved specially for this work, for the most part from original sources; and these are so interspersed that they add much to the value and elucidation of the text. The typography is exceptionally good, errors very few, and the paper and binding show interested and careful publication.

Correspondence.

PREGNANCY SUBSEQUENT TO VENTRAL SUSPENSION OF THE UTERUS.

By J. C. RUTHERFORD, M.D.,
of Providence, R. I.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

IN the JOURNAL for June 3, 1899, I reported a case of ventral suspension of the uterus, followed by normal pregnancy and labor. To that report I wish to add that Mrs. X. was taken in her second labor at 6 A.M., March 31, 1900. The head presented with the occiput posterior. The pains were vigorous and regular, and she was delivered, unassisted, of a large female child at 11.45 A.M. Rotation of the occiput to the pubes did not take place. Her lying-in was brief and uneventful.

Examination, September 12, showed the uterus to be in the normal antverted position. The ligament attaching uterus and abdominal wall is, as nearly as can be made out by bimanual examination, about $\frac{1}{2}$ inch long.

DR. KIRKBRIDE'S SLIDE FORCEPS.

By JOHN LESIURE, M.D.,

Clinical Assistant, Department of Laryngology, Vanderbilt Clinic, New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

DR. KIRKBRIDE'S article in your issue of September 8 reminds me of a forceps devised by me for the purpose of holding glass slides during the process of fixing, staining, etc. This forceps was described and illustrated in an article which appeared in the *Medical News*, May 6, 1899, so I can claim priority as far as the idea of originating an instrument of this kind is concerned. Dr. Kirkbride in his article states: "No attempt, as far as I know, has been made to avoid the staining and burning of the fingers which so frequently occur when the staining solution is poured on the slide and heated over a Bunsen burner," so I am sure he could not have known of my attempts in the same direction. His forceps is much simpler, and as efficient, perhaps more so, than the one described by me, and is constructed upon an entirely different principle. Having felt the need which Dr. Kirkbride has expressed for an instrument of this nature in my bacteriologic and hematologic work, I welcome this improvement with much satisfaction. It is, I think, the acme of ingenuity and simplicity.

RUBBER TAPE IN MINOR SURGICAL OPERATIONS.

By M. H. MUTSCHLER, M.D.,
of Philadelphia.

To the Editor of the PHILADELPHIA MEDICAL JOURNAL:—

I WAS surprised to see in a recent number of the JOURNAL the letter "Rubber tape in minor surgical operations." I do not deny that the doctor's treatment gave a satisfactory result, but such treatment is absolutely adverse to the first principles of surgery, and should not only receive disapproval, but should be severely condemned. Such treatment is sometimes seen in large machine shops where the minor injuries are washed with some antiseptic solution, after which some form of "sticking plaster" is placed over the

wound. When these patients report to the physician the following day, they almost invariably present a very nasty smear and mass of infection. All cases of injured fingers or toes, where the accident has been of a crushing nature, and when not severe enough to warrant amputation, should be thoroughly cleansed with antiseptic solutions, after which the wound margins should be carefully brought into position, if necessary introducing a few stitches to keep the margins of wound in apposition, and at the same time leaving place for drainage. A wet bichlorid dressing should be applied, and the part placed on a splint. As it is almost impossible to remove all the dirt from a wound of this nature, such wounds should be dressed daily for the first few days. Being connected with one of the largest surgical dispensaries in this city, where we treat a large number of injuries of this class, my experience has taught me that the above treatment is the most judicious. I sincerely hope that no physician in these days of antiseptic surgery will treat an open wound with any form of adhesive plaster.

PRECOCIOUS MENSTRUATION.

By HENRY A. STRECKER, M.D.,
of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THERE have been recently reported in your JOURNAL two cases of so-called precocious menstruation. Two of your correspondents consider this name as applied to the two cases a misnomer. The fact that a child has a vaginal bloody discharge shortly after birth, does not constitute it a menstruation. As your correspondent in your issue of September 22 states, it may be due to conditions foreign to the uterus. The case that I desire to report will, I think, be accepted as a true case of "precocious menstruation." The patient is L. M., aged 3 $\frac{1}{4}$ years. Birth was normal. Shortly after birth a bloody discharge escaped from the vagina. This continued for a few days and gradually disappeared. The condition excited no special comment as I had seen it in several other cases. Eighteen months later the bleeding returned. The onset was accompanied and preceded by severe abdominal pains. The discharge lasted for two days. Two months later it again returned, ushered in by the same symptoms of pain. The following month the same condition prevailed, and also two months later. For the next five months nothing of the kind occurred, but then it made its appearance and has done so regularly every 28 days. The onset is always preceded by pain for 24 to 36 hours.

An interesting feature of the case is that the menses in the child appear on the same day as that of the mother. The face and development of the child are those of precocity. Her two brothers, both of whom are older, are what would be termed delicate children. She is stronger and larger than either and weighs more than the eldest brother, who is five years her senior. Her bones are large and her muscles are well developed. Her mammary glands are large and stand out well from the chest. At the menstrual period the complaints of pains shooting through them. Hair is beginning to make its appearance on the pubes.

There is nothing abnormal in either the mother's or the father's family. The mother began menstruating at about 15 and has been perfectly normal.

Five months ago I delivered the mother of another female child. Up to now this child has shown no abnormality. It will be of interest to observe this child and see if any such

condition of precocious menstruation will develop in her at about the age of 18 months as appeared in her sister.

324 So. 12th Street.

ERGOT POISONING.

By FRANCIS M. O'GORMAN, M.D.,

of Buffalo, N. Y.,

Second Assistant at City Hospital for Women.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

AMONG the correspondence in your issue of September 1 appears the report of a case of "Acute Ergot Poisoning," from the pen of Dr. E. S. Clouting, of Germantown, Pa. The report is very interesting to me, because a typical case of ergotism came under my observation during June. Being called about 7 P.M. in a hurry by a young husband, I found his wife in a comatose condition. Her pulse was very low (58), weak and small, respiration labored, and temperature 98°. I noticed while watching her, that the flexor muscles of her forearm underwent severe tonic contractions at intervals of a few minutes. Later on the flexor muscles of the thigh and leg underwent similar contractions. The husband told me that at the supper table she became giddy, laughed hysterically, and then seemed to faint and have a convulsion. Upon questioning him, he produced some medicine which, he said, she had been taking for four days because menstruation had failed to appear. The medicine was fluid extract of ergot, and she had taken it in dram doses every four hours. The patient was removed to the City Hospital, where she remained unconscious for about three days, minim doses of tincture of aconite, and one-eighth grain doses of morphin sulfate being given every two hours. Hot applications were applied to her body, and cold to her head continually for a week. Three days after entering the hospital, the rolling of her head and eyes ceased, but the contractions of her flexor muscles continued at indefinite intervals. Constipation was marked, but urination was free. The pupils were widely dilated, and she still complained of the light hurting her eyes. Purpuric spots appeared on her neck, arms, and limbs, which have not entirely disappeared yet. Her pulse was as low as 56, and for two weeks never went above 70, with the temperature at 98°. These facts, together with the rolling of the head and eyes, the dilated pupils, the tonic contractions of the flexors, constipation, headache, and pain in the abdomen, will probably aid in answering Dr. Clouting's question regarding vasomotor paralysis.

PSEUDOMENSTRUATION (?).

By H. BROOKER MILLS, M.D.,

of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I HAVE been very much interested in reading the four communications on this subject which have appeared during the past few months in the columns of the JOURNAL, and, with your permission, should be glad to report a case which recently came under my observation, particularly as I think it bears out the points so ably expressed by Dr. Mundé in his communication of September 22.

A. B., born at term after a normal labor of only a few hours, was the third child of healthy parents and apparently was perfectly healthy at the time of birth. At the age of one week the nurse called my attention to the existence

of what she termed a bloody discharge from the vagina, and upon separating the labia I discovered a small amount of reddish-colored liquid, but was unable to determine its origin. A day or two later Dr. W. C. Hollopeter was called in consultation, owing to my inability to find any food which agreed with the child, and his attention was called to this supposed pseudomenstruation. We examined the parts carefully and came to the conclusion that, beyond the shadow of a doubt, from our knowledge of the parents and the other children, together with the information secured by the examination, the reddish-colored liquid was blood from an abraded urethra due to the passage of uric-acid crystals. In three or four days the discharge entirely disappeared and up to the present time (two weeks later) there has been no return. After many attempts to secure some urine the nurse finally succeeded and examination showed the presence of uric acid, thus confirming the diagnosis. The parents, especially the father, suffers from the uric-acid diathesis, so that it is only natural to suppose the child should inherit this condition.

A point of interest in connection with this case is that the second child, who is now 2½ years old, almost died from several umbilical hemorrhages, which occurred immediately after the falling-off of the stump of the cord. This case was reported by me in the PHILADELPHIA MEDICAL JOURNAL of January 21, 1899.

PSEUDOMENSTRUATION.

By JOHN C. KAMP, M.D.,

of Buffalo, N. Y.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

Seeing several cases of pseudomenstruation mentioned in the JOURNAL, I wish to add a case which came under my observation and which has not been reported.

I confined Mrs. W. on the 18th day of August, 1898. Four days later I was summoned in great haste and found the mother very much frightened over a serobloody vaginal discharge from the infant. She said that the only other daughter, born to her some 3 years previous, had a similar discharge, which lasted several months, when she died. In the case of the one under my observation the discharge stopped on the third day, and there has been no recurrence.

FOOD-VALUE OF ALCOHOL.

By HOWARD S. ANDERS, M.D.,

of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

Is alcohol a "partial food"? In a JOURNAL editorial on August 18, Professor Hall's recent criticism of Professor Atwater's now famous calorimeter experiments is referred to, and the latter's correction of certain "misapprehensions and misstatements of his critics" mentioned and, if I apprehend correctly, his position as to the food-value of alcohol endorsed.

It is the logical consistency of that position that I cannot appreciate; nor, in his latest utterance, does Professor Atwater uphold the logic of his former claims so notoriously, since he states his belief that total abstinence is the best stand to take in regard to alcoholic beverages, so-called. Would he, could he consistently say that alcohol was "in a sense a food"? Obviously, here as in many other discussions—theological, philosophical and political, as well as medical—everything depends more or less at the outset upon a mutually admitted understanding of the meaning of the fundamental

and focal terms used in the statement of the question at issue; and this alcohol question will not be settled until it is settled right, including terms, propositions, evidence and inference; and whether alcohol is to be considered a food or not depends upon a generally accepted definition by competent scientific men as to what a food really is. As elsewhere, there is properly no room for hairsplitting or casuistry here.

We may agree, then, with the implied or expressed idea of a food as being a substance that, through metabolism, builds up normal structure and supplies waste of tissue, in a normal manner. But I do not desire to argue the broad question of alcohol as a food or not a food. I do not agree, however, with the Atwater mode of reasoning which calls alcohol a "partial food," simply because it appears to have one quality alone of a food, namely, that it is oxidized when taken in moderate quantities. Does that make it in any sense a food? Should the term *food* be applied to it at all, when there are *drugs* of which no less may be said than is thus claimed for alcohol? Is there really such a thing as a partial food? Rather, is it not as misleading or demoralizing as to speak of a "half-truth"? To quote the French jurist, Jacques Cujas: "What is not a whole truth is a whole falsehood, not a half-truth." But Professor Atwater would have us believe that alcohol is a partial food because it has the one property of yielding some energy as a result of oxidation in the body, and this in a negative, abnormal and narcotic way by depressing cellular activity.

The fallacy is right on the surface, too, in the editorial reference to Professor Atwater which says, in one place, that "alcohol may be called a partial food when taken in moderate quantities;" and a little further on, that "the moderate use of alcohol is dangerous," a manifest contradiction. Illogical, compromising thinking cannot truly harmonize conflicting facts and evidence.

And so regarding the teaching of temperance to children with the aid of the current textbooks on physiology. If it "is wrong to teach that alcohol in small quantities is always necessarily harmful," it is equally wrong to teach that it is in any sense a food, in the ordinarily accepted and complete meaning of that term. Perforce, in view of these alternatives, it is *neither a poison nor a food*, but stands by itself, unclassified, unless it be in relation to other facts or conditions that render its classification clear and easy. And it is precisely at this point that I wish to emphasize what I believe to be the true relative position of alcohol: it is always, naturally, essentially, rationally and ethically a *drug*, to be used, in whatever form,—the simpler and purer the better—with the cool, scientific deliberation and clear, sympathetic discrimination that morphin, nux vomica, calomel, or any other drug is or should be used; not according to the rule of thumb and fingers of the saloon drink of custom and mere tradition so common in much of our hospital and private practice.

I hold that our modern knowledge of alcohol in the human body justifies the belief that in health it is never a food in any sense, be the quantity small or large, but always a poison, biologically or physiologically speaking; that in disease it is neither a food nor a poison, but may be a suitable and helpful drug; and that neither in the last analysis or fullest synthesis, in health or disease is it a "partial food," in small, so-called moderate, or excessive quantities. Let us call it what it rightfully is, a *drug*, and *not a drink, a narcotic, and not a tonic*. It may take a generation or two before this view becomes as universal as one might wish, but I hope and believe that then it will so become.

SEPARATE URINES SIPHON.

By ANDREW J. DOWNES, M.D.,

of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

In your issue of July 21, 1900, is a letter from Dr. M. L. Harris criticising the claims in my article of June 2 on the separate urines siphon. I have used both the Harris segregator and my siphon as I prefer to call it often enough to know that the smaller caliber, simpler curve at the beak end and the absence of a spring for elevating the partition rod make the use of my instrument much less distressful to the patient at the time, and subsequently there is no irritability of the neck of the bladder which was generally caused by his instrument. In regard to the claim "the introduction of a new feature siphonage alone for the withdrawal of the individual urine," which is the essential difference between my instrument and that of Dr. Harris, I feel this is justifiable. I aim by this instrument to obtain a partitioned bladder with a fairly deep sulcus or pocket on each side from which siphons with only one opening in each withdraw urine. The single opening I consider essential and this leads from the most dependent part of the pocket. This opening has no immediate connection with the opening of the ureter, so that a little variation in the distance between the openings of the ureters makes no difference. The urine as emitted from the ureters has, I believe, sufficient gravity to descend to the bottom of the sulci prepared for it. I am aware that when a catheter is placed in the bladder with the patient in the dorsal position that contraction occurs and the walls of the bladder approximate each other, yet not I believe so closely as to prevent the few drops from the ureters going by gravity to the respective sulcus prepared for it and from whence it is immediately siphoned out and at about the rate it enters the bladder from the ureter. Intermittent siphonage is maintained as described in my article. Dr. Harris' argument as to the necessity of suction apparatus with his instrument does not apply to urine. Mine is a siphon, his is not. In developing my instrument I thought of surrounding a very narrow beak with the opening in the very end, as now, by an outer perforated shell which would conduct urine from the higher levels as it emerged from the ureter to the bottom of the sulcus, an instrument theoretically and practically the same as it is now made, but perhaps more certain. My success, however, has been such as to make me feel that it may not be necessary. I have been out of practice for three months, and, excepting a few opportunities to use the siphon in Berlin, have not paid much attention to it this summer. In Berlin I used it on a private case for Dr. Freudenburg and easily obtained purulent urine from one side and clear urine from the other. In this case, after repeated attempts, Dr. Freudenburg had failed to catheterize either ureter. I also used it on a private case for Dr. Leymann and demonstrated pus coming from one side. In Dr. Knorr's clinic, with the assistance of Dr. Bierhoff, of New York, the following demonstration was made: A catheter was placed in the left ureter and my instrument then placed in the bladder and the bladder emptied. Urine then began to flow from the right side only of my instrument, while the left kidney urine came from the catheter placed in the left ureter. This was allowed to continue for about 15 minutes. The catheter was then removed from the ureter and immediately identical urine began to flow from the left side of the instrument and at the same rate that it had come from the catheter. We had here a positive proof of the efficacy of the

siphon. A proof that it requires no suction apparatus, and, therefore, a proof of a more or less radical difference from the Harris segregator. With few exceptions I have used the urine siphon on the female; the exceptions seem to indicate that it will be as practical in the male.

This summer I learned that Dr. Alfred Neumann, of Berlin, in 1897 had made, used, and published a description of an instrument which he called "Harnscheider." It could be used only in the female. I have seen it and do not consider it very practical. It is, however, a segregator. Dr. Harris' instrument is far superior to it. I am sure mine is simpler and, in some respects radically different from the Harris instrument. Notwithstanding ureteral catheterization in both sexes has now become quite practical to experts, there are very many reasons why a simpler method of obtaining the individual urine is desirable. In the interest of renal surgery I, for one, trust that a more useful instrument even than mine may yet be produced.

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Calendar of Meetings of Philadelphia Medical Societies for the week ending October 20, 1900:

Tuesday, October 16—College of Physicians, Section on Ophthalmology.

Friday, October 19—College of Physicians, Section on Orthopedics.

Titusville, Pa., is to have a hospital. The structure will cost about \$15,000.

The Home of the Holy Child for Colored Children, of Philadelphia, is under quarantine because of diphtheria in that institution.

Philadelphia Board of Charities and Correction.—William J. McLaughlin has been appointed a member in place of Dr. Joseph Neff, resigned.

Lock Haven Hospital.—A building site of 4 acres has been given by Wilson Kistler, of Lock Haven, Pa., for a hospital at that place. A building fund is now being raised.

Public Baths.—While the 9 public baths of Philadelphia were open, from June 25 to September 30, they were used by 1,271,278 men, 19,996 women, 3,594,260 boys and 74,221 girls.

At the Philadelphia Almshouse 4 graduates in dentistry will be added to the staff of residents. One is to be chosen from each of the 4 schools of dentistry here. They are to receive no salary.

University of Pennsylvania.—George F. Barker, M.D., Ph.D., for 28 years professor of physics at the University, has resigned because of ill health. The title of "Professor Emeritus in Physics" has been conferred upon him.

Pollution of Navesink River.—The New Jersey State Sewerage Commission has ordered a hearing, October 15, for the purpose of deciding on ways and means of stopping the pollution of the Navesink River at Red Bank. The condition has become intolerable.

Druggists Aroused.—A special agent of the State Pharmaceutical Examining Board is endeavoring to ascertain the competency of drug-clerks, and also the cautions observed in the sale of poisons in Philadelphia. It is believed that an effort is to be made to have the Legislature pass more stringent laws governing the sale of drugs.

College of Physicians.—By the will of the late Dr. Alfred Sullé, of Philadelphia, the College of Physicians will receive all the medical works contained in the decedent's

library. With the exception of certain pictures and papers, the remainder of the estate is left to relatives to revert to the College of Physicians if these leave no heirs.

Episcopal Hospital.—The will of the late Charles Edward Orme, of Philadelphia, devises his entire estate, valued at \$50,000, to the Episcopal Hospital "to maintain as many free beds, to be known as the Charles Edward Orme Free Beds, as the income will support." The bequest is not available until the death or remarriage of his widow.

Obstetrical Society of Philadelphia.—At a meeting held on October 4, Dr. WILMER KRUSEN read a paper upon **Varicose veins of the vulva complicating pregnancy**, reporting a case in which the veins became as large as a fetal head during the last months of pregnancy. He also exhibited a specimen of **ovarian dermoid**. Dr. E. E. MONTGOMERY read a paper on **Methods of hemostasis** in which the use of Doyen's angiotribe was advocated, using it only for crushing a groove in the tissue along which a ligature should be subsequently applied. He does not believe in depending upon the angiotribe alone for the control of hemorrhage. The use of a sterilized catgut ligature applied to the crushed tissue is the most effective method of controlling the bleeding and avoiding any secondary hemorrhage.

Vital Statistics of Philadelphia for the week ended October 6, 1900:

Total mortality	334
Disease.	Cases. Deaths.
Inflammation of appendix 3, brain 4, bronchi 4, kidneys 13, liver 1, lungs 18, nerves 1, peritoneum 4, pleura 2, stomach and bowels 20, uterus 1, veins 1, heart 1	73
Lungs—tuberculosis of 46, congestion of 1	47
Debility 3, inanition 14, marasmus 14	31
Heart—disease of 27, fatty degeneration of 1	28
Uremia 16, Bright's disease 5	21
Carcinoma of breast 1, jaw 1, intestines 2, liver 2, lungs 1, peritoneum 1, rectum 1, stomach 2, uterus 1, sarcoma of breast 1, jaw 2, knee 1, tumor of bladder 1, uterus 1	18
Apoplexy 8, paralysis 7	15
Diphtheria	14
Convulsions 8, puerperal 1	9
Cholera infantum	8
Casualties	8
Typhoid fever	6
Old age	6
Croup 1, membranous 4	5
Hemorrhage—brain 2, uterus 2, umbilical 1	5
Brain—congestion of 1, softening of 3	4
Suicide—gas 1, shooting 2	3
Cirrhosis of liver	3
Unknown	3
Dropsy 2, abdominal 1	3
Scarlet fever	30
Pelvic abscess 1, ovarian 1, asphyxia 1, asthma 2, anemia 1, carbuncle 1, tuberculosis of the bowels 2, cyanosis 2, diarrhea 1, dysentery 1, kidney disease 1, epilepsy 1, malaria 1, jaundice 2, obstruction of the bowels 2, surgical shock 1, sore mouth 1, traumatic tetanus 1, whooping-cough 1	

NEW YORK.

Gouverneur's Hospital.—Dr. Agnew H. Hilsman is the successor to house surgeon Dr. Frank P. Leadley.

The Homeopathic Hospital, of New York, cost the city \$60,000, and recently \$149,000 has been asked for to equip and maintain it.

Tuberculosis.—At a meeting of the New York Board of Health it was stated that during the past year there were over 40,000 cases of tuberculosis in that city.

The State Forest Preserve Board of New York has just purchased 16,000 additional acres in the Adirondacks, at prices ranging from \$1.50 to \$6.50 an acre.

An Excursion for Nurses.—Mr. Elbridge T. Gerry recently took a party of 70 nurses from the New York Hospital School on an excursion up the Hudson on his steam yacht *Electra*.

New York Polyclinic Hospital.—Dr. Morrison, a graduate of Queen's, Kingston, Ont., has been appointed house surgeon of the New York Polyclinic Hospital.

Claim Against Dental Company.—A claim to collect \$2,000 damages has been made by Gustav Altenburg against the New York Dental Company because a sound tooth had been extracted in place of a decayed one.

Fraudulent Use of Soft Coal.—In New York City the Board of Health arrested 7 persons and issued warrants for nearly 100 others, who, owing to the rise in the price of anthracite coal, have violated the law relating to smoke by burning bituminous coal.

The Carnegie Laboratory of New York City, in which was prepared the pathologic exhibit for the recent meeting of the American Medical Association at Atlantic City, has, through the generosity of Mr. Carnegie, been recently refitted for elaborate bacteriologic and histologic research.

Homeopathic Home Remedy Company.—Suit has been brought against the Munyon Homeopathic Home Remedy Company by William Spiers, of Brooklyn, for \$10,000 damages for the loss of an eye which he says was injured by the explosion of one of the company's patent inhalers. The defence contends that he did not follow directions.

A Testator Objects to Chaplains.—A recent bequest of \$50,000 to the Geneva, N. Y., City Hospital contains a peculiar clause stipulating that the Hospital "shall not have an officer known as a chaplain, or have any person in its service at any time any part of whose duties it shall be to perform such services as are usually performed by a chaplain." Provision is made that in case the stipulation is not complied with, said bequest shall revert to the estate of the testator and then be given to the Rochester City Hospital.

Yellow Fever in First Cabin.—E Bertweert, one of the saloon passengers of the Ward Line steamer *Havana*, who was transferred to Hoffman Island for the customary observation, was suddenly taken sick there with symptoms of yellow fever. Dr. Doty, Health Officer of the port, ordered him sent to Swinburne Island. Later, the previous diagnosis was fully confirmed. It is the first case brought to New York in the saloon cabin this year. Dr. Doty is reported to have said the patient is as comfortable as can be expected, and that it is too early to make any prognosis.

NEW ENGLAND.

Another Hospital for Springfield.—The united protective societies are contemplating founding another hospital in Springfield, Mass.

Superintendent of Poor.—Dr. Joshua F. Lewis has been elected superintendent of adult poor by the Massachusetts State Board of Charity in place of Dr. Stephen C. Wrightington, deceased.

Chelsea Hospital.—The Government has appropriated \$45,000 for the improvement of the United States Naval Hospital at Chelsea, Mass. Larger buildings are to be provided, and plumbing and ventilation regulated.

Typhoid from Mussels.—At Portland, Me., 4 members of an Italian crew are in the Marine Hospital with typhoid fever. An investigation revealed the fact that members of the crew had been eating mussels gathered from the pile beneath the wharf. A sewer empties into the dock near the wharf.

Maine's Next Governor a Physician.—John F. Hill, the next Governor of Maine, is one of the few physicians of the country who have entered or been successful in the political field. He took his degree of M.D. from Bowdoin Medical School. This is not the first time that a physician has occupied the gubernatorial chair of Maine, Dr. Garcelon having served as Governor of the State with distinction.

New Hospital at Pittsfield.—A new hospital or at least an important addition to the House of Mercy Cottage

Hospital will soon be built in Pittsfield, Mass. The late Solomon N. Russell bequeathed the tract of land known as "Russell Ems," opposite the House of Mercy, to that corporation, for the purpose of an additional hospital. The present buildings are taxed to their fullest capacity. The old House of Mercy building will then be used as a maternity hospital.

CHICAGO AND WESTERN STATES.

Vaccination.—A death from blood-poisoning caused by vaccination is reported from Indianapolis, Ind.

The Medical Association of Colored Physicians held its annual convention in St. Louis, Mo., the first week in October.

Barber's itch is epidemic in Milwaukee, Wis., and is causing much annoyance to barbers and their patrons, and making necessary stringent antiseptic measures.

Chicago Polyclinic.—Dr. J. Rauson Pennington, formerly of the Chicago Clinical School, has been appointed to the chair of rectal surgery in the Chicago Polyclinic.

Anthrax is killing many cattle near Crow's Landing, Cal. The germ is found in the water of a canal where the cattle drink. Some weeks ago the disease existed 40 miles further up the canal.

Passengers Vaccinated.—The steamship *Nome City*, 10 days from Cape Nome, was not allowed to proceed from Port Townsend to Seattle until her 386 passengers were vaccinated. This was considered necessary because there has been another outbreak of smallpox at Nome, although the vessel had no sickness aboard.

Better Hospital Service.—The chief surgeon of the Southern Pacific's hospital department, in order to advance its efficiency, will send one of his assistants East annually to visit the leading medical institutions and study the latest methods of surgery. Dr. W. B. Coffey, of San Francisco, Cal., is the first one to enjoy the privilege.

The Indiana State Board of Health reports a great increase in typhoid fever, and diphtheria and smallpox has been reported in 9 counties. In view of these facts the State Board will send to all applicants without cost pamphlets on the prevention of diphtheria, scarlet fever, and smallpox. A pamphlet on the prevention of typhoid fever is in preparation.

Osteopathy.—The first notes in proceedings against the osteopaths in Wisconsin have been sounded in Milwaukee. The first test case will be heard in a few days. A large "College of Osteopathy" exists in Milwaukee and they have retained one of the best law firms in the State. Judge Neelan, before whom the case will be tried, is the Judge who convicted the "Christian Scientists" some months ago.

A surgical operation for kleptomania is reported from Alameda Co., Cal. The patient is a boy of 10. Some years ago he received a severe blow on the head and since then he has been a kleptomaniac and has been inclined to torture or murder his playmates. The skull has been trephined at the point injured, pressure on the brain relieved and the surgeons look for a complete moral change in the boy.

Sanatoriums for the Tuberculous.—Application has been made by the Ancient Order of United Workmen, the Woodmen, and the Odd Fellows, for permission to erect a sanatorium for the tuberculous on the Government reservation at Fort Stanton, 150 miles south of Santa Fé, N. M., where the United States Marine Hospital for the Tuberculous is located. The Government has also under consideration a plan to allot each State desiring it, ground for a sanatorium.

Brain and Brawn.—In Chicago during the last 12 months, 7,000 school children have been carefully measured and tested, and it has been found that size and strength of body give an indication of proportionate brain power. Pupils, 12 years of age, in the eighth grade average 5 inches more in height and proportionately more in weight than second grade scholars of the same age, and it is a reasonable deduction that brain power and size and strength go together.

The San Francisco Board of Health has appointed 2 food inspectors. An ordinance intended to regulate the maintenance of slaughter and packing houses and to prevent the sale of watercress and other edible vegetables growing near cesspools or on lands into which any sewage or impure matter is emptied has been adopted. Plans for the new Nurses' Home at the City and County Hospital, to cost \$2,000, have been filed and referred to the Hospital Committee.

Tax on Physicians.—In Oregon, physicians and lawyers are required to pay a license. Dr. E. B. Miller, of Portland, in commenting upon this tax, says that the public apparently has little or no appreciation of the amount of charity work done by the medical profession, that many practicing physicians of Portland do from \$1,000 to \$10,000 worth of charity work in a year, thus taking from the city a large burden. The nature of the medical profession seems to impose upon its members the duty of bearing this burden for society, and they are entitled to credit for it in summing up the amount of revenue to be drawn from them.

Tuberculosis and Public Health.—A Michigan jury is to determine whether tuberculosis is a "disease dangerous to public health." A statute of that State makes it the duty of a physician to report cases of smallpox, cholera, diphtheria, scarlet fever, "or any other disease dangerous to the public health." A physician was arraigned recently for failing to report a case of tuberculosis. The judge decided that the statute was not intended to cover tuberculosis and ruled out testimony offered to show that it is a "disease dangerous to public health." The physician was acquitted. On appeal to the Supreme Court it was decided that the question should be determined on evidence and should have been submitted to the jury. A new trial has been ordered.

SOUTHERN STATES.

Typhoid Fever.—An epidemic of this disease prevails in Washington, D. C. Impure water is thought to be the cause of the outbreak.

Galveston Sanitation.—Dr. George Loper, a New York sanitary expert, is directing the work of putting the streets of Galveston in a sanitary condition.

Hebrew Hospital.—An additional memorial fund of \$500 has been donated to the Hebrew Hospital Association of Baltimore by Mrs. Florence Eversman.

Bequests to Charity.—By the will of the late Simon Stein, of Baltimore, the Hebrew Orphan Asylum and the Hebrew Hospital and Asylum Association each received \$250.

Permitted to Practise Medicine.—The report of the Board of Medical Supervisors of Washington, for the past fiscal year, shows that 50 applications to practice in the district were made and of this number 37 passed.

A School for Colored Nurses has been established at Greenville, S. C. The course of study covers a period of 2 years. Applicants for admission must not be less than 18 years of age, and they are examined on all the English branches.

Municipal Hospital Site.—All proposals for the purchase of ground as a site for the new municipal hospital in Washington have been rejected. The prices asked are too high. Private negotiations for particular sites will now be made. The sum available is \$100,000.

St. Vincent's Hospital, at Birmingham, Ala., is nearly ready for occupancy. The electric outfit alone cost \$10,000. St. Vincent's, in its central building, has four clear stories above the basement and a roof story, and will have at the start a capacity for 200 beds. There are 40 bathrooms.

Quarantine Abolished.—The Louisiana State Board of Health has reduced by 2 weeks the quarantine against Central American ports, and after October 15 all vessels from ports on the Gulf and Caribbean, where there is no yellow fever, will have open communication with New Orleans.

Physician Sued.—Suit has been brought against Dr. Edward J. Bernstein, of Baltimore, by Henry Garlach to recover \$10,000 damages for the death of his son, who, it is alleged, was unskillfully treated by the physician.

Richmond (Va.) News.—Dr. Henry L. Smith, president of Davidson College, North Carolina, addressed a large gathering of citizens and students of the University College of Medicine, Richmond, Va., on its opening, upon the subject of the value of true science in education. Up to October 6, 1900, 230 students have matriculated. At the Medical College of Virginia, 196 students have registered. Both schools show an increase of new students over last year. Dr. Landon B. Edwards has been elected professor of clinical medicine in the University College.

CANADA.

A hospital for contagious diseases at Westmount, Montreal, to cost \$75,000, is under contemplation.

MISCELLANY.

Quarantine.—Against the yellow fever infected ports of Southern Mexico a strict quarantine is being enforced by the authorities at El Paso, Texas.

School Sanitation.—The Medical Society of Nova Scotia offers a prize of \$10 to the pupil under 16 attending the public schools of the Province for the best essay on "School Sanitation."

Free from Yellow Fever.—For the first time in 4 seasons the quarantine year just drawing to a close has been free from yellow fever in the United States, and the season is now so far advanced as to give assurance against an epidemic. At the beginning of the quarantine season the Marine-Hospital Service appointed 7 acting assistant surgeons in as many cities on the Atlantic coast of Central America at the fruit ports to put in operation quarantine measures.

Investigating Yellow Fever.—The expedition under Drs. Durham and Myer, sent out by the Liverpool School of Tropical Medicine to study yellow fever in South America, received a cordial welcome from the authorities at Washington and Baltimore, and at the special request of Dr. Sternberg, Surgeon-General of the United States Army, has gone to Cuba with the American Government expedition to study yellow fever in Havana. From this point it will proceed to Para, its original destination.

Yellow Fever Serum.—Several years ago the Mexican government made a standing offer of \$100,000 to the discoverer of a remedy for yellow fever. Experiments have recently been conducted at Vera Cruz by Dr. Angel Bellinzaghi, a young Italian specialist, under the auspices of the government board of health. The commission appointed by the board to witness the experiments has reported favorably and the physician will be given part of the prize at once. He has been asked to make further experiments in various forms of the disease at Vera Cruz, and if they are successful he will win the entire prize.

Yellow Fever in Cuba.—Private letters received from Havana indicate that much apprehension exists among the Americans there regarding the yellow fever, as the condition grows worse instead of improving. Civilian employes in Cuba seem to be subject to the disease, and in several Government offices many have been stricken. There is yet no fear of the fever spreading among the troops. During the month of September 257 cases were officially reported, with a mortality of 25%. There are now 84 cases under treatment. Many cases are not reported at all as yellow fever, because of the non-development of the albumen symptom, although all the other symptoms are unmistakable.

Insanity in the Army.—It has been asserted that the percentage of discharges from the army on account of insanity has been excessive, an alarming increase on the record of previous years. The forthcoming annual report of the Surgeon General of the Army will throw some light upon this subject and will show that there is no such abnormal prevalence.

lence of insanity in the military service as is charged. It is true there are many cases reported by surgeons in the Philippines as insane, and the men thus supposedly affected are sent home on transports, but it has been found that in a majority of these cases the disability is removed by the time the patient reaches San Francisco, and the soldier is thereupon continued in the service and sent to one of the home battalions. The surgeons attribute the alleged cases of insanity to severe mental depression, a debility of the nervous system due to acute attacks of homesickness. The report for the calendar year 1899, show that there were 188 cases of insanity among 105,546 men, of which 58 cases occurred among 42,192 men in the United States, 84 cases among 39,280 in the Pacific Islands, 14 cases among 3,727 men in Puerto Rico, and 32 cases among 29,051 men in Cuba. Of course, the small force in Puerto Rico does not justify conclusions, but taking the 188 cases from the army-at large, it will probably be disclosed in General Sternberg's report that hardly half of these cases were those of actual insanity. The results will probably show that the percentage of insanity, as a disability among the troops, is not much higher now than in previous years. There has been a great deal of interest in the subject, and one of the most important passages in General Sternberg's report will be that which deals with insanity in its relation to the foreign service now demanded of the army.—[Army and Navy Register.]

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended October 6, 1900:

SMALLPOX—UNITED STATES.

Obituary.—WILLIAM W. BROWNING, of Brooklyn, N. Y., aged 48.—JAMES W. BRYANT, of Richmond, Va., September 29, aged 79.—STEPHEN E. D. HOCRNBEEK, of Ellenville, N. Y., aged 66.—S. POTTS EAGLETON, of Ocala, Fla., September 18, aged 33.—R. F. CARMICHAEL, of the Kingston General Hospital, Ontario.—CRAWFORD IRWIN, of Hollidaysburg, Pa., October 8, aged 76.—ALEXANDER LEWIS, of Arilene, Kan., October 8, aged 67. COLONEL JOSEPH BAYSON WRIGHT, Assistant Surgeon General, U. S. Army, of Washington, D. C., October 9. Colonel Wright was the son of Brevet Brigadier-General J. J. B. Wright, surgeon, U. S. Army, a distinguished officer of the Medical Department. He graduated in Arts at Dickinson College, Carlisle, Pa., July, 1858, and in Medicine, March, 1860, the degree of Master of Arts being subsequently conferred upon him in the following year, 1861. His record of service is one extending back to the early years of the Civil War. He entered the service as assistant surgeon on May 28, 1861; was promoted to a captaincy on May 28, 1866; to a majority on July 23 of the same year; as lieutenant-colonel on April 23, 1889, and attained his final rank, that of colonel and assistant surgeon-general, on May 17, 1894. During the Civil War his service was principally in the Departments of Ohio and Cumberland, with General Grant's army in the field at Florence, Miss., and upon various executive duties as medical purveyor and assistant medical director. His long service necessarily took him to various posts and stations, chiefly in the West. He was ordered to the Military Prison at Fort Leavenworth, Kan., in July, 1884, at which place he served many years. During his more recent service Colonel Wright served as medical purveyor in charge of the large depot in St. Louis from December, 1893, until he was detailed as chief surgeon, headquarters Department of Dakota, St. Paul, Minn., November 24, 1899. At the time of his death he was on leave of absence pending his retirement on December 25, 1900.

Changes in the Medical Corps of the U. S. Army for the week ended October 6, 1900:

EKWURZEL, GEORGE M., acting assistant surgeon, is relieved from temporary duty at the Presidio and will proceed to Portland, Oreg., where he will report to the commanding officer on the transport "Thyra" for temporary duty during the voyage to the Philippine Islands. Upon arrival at Manila Acting Assistant Surgeon Ekwurzel will report to the commanding general, division of the Philippines, for assignment to duty.

ROSS, CHARLES A., acting assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will report to the commanding officer, First Battalion, Fifth Infantry, now in camp at that station, for duty with that battalion, to relieve Acting Assistant Surgeon Wharton B. McLaughlin.

McLAUGHLIN, WHARTON B., acting assistant surgeon, will report at the Army General Hospital, Presidio, for temporary duty awaiting transportation to the Philippine Islands.

WILLIAMS, ABRAHAM D., acting assistant surgeon, will proceed on U. S. transport "Ingalls" to Mayaguez, P. R., for temporary duty at that post.

BURKART, JOHN L., acting assistant surgeon, will proceed to Seattle, Wash., where he will report to the commanding officer on the transport "Port Albert" for temporary duty during the voyage to the Philippine Islands. Acting Assistant Surgeon Burkart is authorized to carry with him extra baggage (medical supplies) not to exceed 200 pounds. Upon arrival at Manila, Acting Assistant Burkart will report to the commanding general, division of the Philippines, for assignment to duty.

MURTAGH, JOHN A., acting assistant surgeon, now at the Army General Hospital, Presidio, is granted leave for 21 days from October 8.

AGRAMONTE, ARISTIDES, acting assistant surgeon, is granted leave for 15 days, with permission to go beyond limits of division of Cuba.

TESSON, Major LOUIS S., surgeon, will proceed from Vancouver Barracks, Wash., to Portland, Ore., and make sanitary inspection of transports "Lennox" and "Thyra."

TEN EYCK, Captain BENJAMIN L., assistant surgeon, is granted leave for two months on surgeon's certificate, with permission to return to the United States.

GEORGE, W. R. S., acting assistant surgeon, will proceed from Adjuntas to Ponce, P. R., for temporary duty during the absence on sick leave of Captain Benjamin L. Ten Eyck, assistant surgeon.

McLAUGHLIN, WHARTON B., acting assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will report to the commanding officer, battalion of the Twenty-fourth Infantry, now in camp at that station, for duty with that battalion, to relieve Acting Assistant Surgeon Thomas G. Holmes.

HOLMES, THOMAS G., acting assistant surgeon, will report for temporary duty as transport surgeon on the Army transport "Hancock," to relieve Acting Assistant Surgeon Robert E. Williams.

WILLIAMS, ROBERT E., acting assistant surgeon, will proceed to Fort McDowell for temporary duty.

BACON, JOHN E., acting assistant surgeon, is granted leave for one month, from October 15.

A board of officers to consist of Lieutenant-Colonel **ALFRED A. WOODHULL**, deputy surgeon-general; Major **JAMES C. MERRILL**, surgeon; Major **EDWARD C. CARTER**, surgeon, is appointed to meet at the Army Medical Museum Building, Washington, November 1, and at such times thereafter as may be necessary, for the examination of officers of the medical department for promotion.

MEARNS, Captain EDGAR A., assistant surgeon, will report November 1 to Lieutenant-Colonel **ALFRED A. WOODHULL**, deputy surgeon-general, president of the examining board at the Army Medical Museum Building, Washington, for examination for promotion.

KIRKPATRICK, First Lieutenant THOMAS J., assistant surgeon, will report November 1 to Lieutenant-Colonel **ALFRED A. WOODHULL**, deputy surgeon-general, president of the examining board at the Army Medical Museum Building, Washington, for examination for promotion.

A board of officers to consist of Major **WALTER REED**, surgeon; Major **JEFFERSON R. KEAN**, surgeon; Captain **ALEXANDER N. STARK**, assistant surgeon, is appointed to meet at Columbia Barracks, Quemados, Cuba, October 22, for the examination of officers of the medical department for promotion.

STONE, First Lieutenant JOHN H., will report October 22 to Major **WALTER REED**, surgeon, president of the examining board at Columbia Barracks, Quemados, Cuba, for examination for promotion.

KELLOGG, PRESTON S., acting assistant surgeon, will proceed from Battle Creek, Mich., to Fort Keough for duty, relieving Acting Assistant Surgeon **Muhlenberg K. Knauff**, who will proceed to his home, St. Paul, Minn., and report by letter to the Surgeon-General of the Army for annulment of contract.

HOFF, Major JOHN VAN R., surgeon, is relieved from further duty with the United States forces in China and will proceed to San Francisco, Cal., and report by telegraph to the Surgeon-General of the Army for instruction.

The date of meeting of the American Public Health Association at Indianapolis, Ind., announced in par. 23, S. O. 202, August 28, this office, to be held October 1 to 5, 1900, is changed to October 22 to 26, 1900.

CURRY, JOSEPH J., acting assistant surgeon, is relieved from further duty as a member of the board of medical officers appointed January 16, 1900, for the purpose of studying tropical diseases in the Philippine Islands.

COSTINE, EDWARD F., hospital steward, and 24 privates of the hospital corps, recently enlisted, Jefferson Barracks, will be sent to Fort McDowell for duty with the hospital corps school of instruction at that post. Steward **Costine** will report to the commanding general, department of California, for transportation to Manila, P. I. Upon his arrival at Manila he will report to the commanding general, division of the Philippines, for assignment to duty in that division.

COWPER, HAROLD W., acting assistant surgeon, is relieved from duty in the department of Puerto Rico and will proceed to New York City and thence to Fort Ontario for duty.

FRICK, Captain ERCLID B., assistant surgeon, is relieved from duty at Fort Wadsworth, and will proceed to San Juan, P. R., and report to the commanding general, department of Puerto Rico, for assignment to duty.

WELLS, Captain GEORGE M., assistant surgeon, is relieved from duty at San Juan, P. R., to take effect upon the arrival at that place of Captain **Euclid B. Frick**, assistant surgeon, and will proceed to Fort Wadsworth for duty.

PAGE, First Lieutenant HENRY, assistant surgeon, is granted leave for 14 days.

MACHON, WILLIAM, hospital steward, Plattsburg Barracks, will be discharged from the Army, by way of favor.

Changes in the Medical Corps of the U. S. Navy for the week ended October 6, 1900:

BYRNES, J. C., surgeon, is detached from the "Massachusetts," October 1, and ordered to the New York Navy Yard.

WAGGENER, J. R., medical inspector, is detached from duty at the Naval Hospital, Yokohama, Japan, and ordered to duty in charge of the Naval Hospital, Cavite, P. I.

WRIGHT, B. L., assistant surgeon, is detached from the Isla de Luzon, and ordered to the Naval Hospital, Cavite, P. I.

VON WEDEKIND, L. L., passed assistant surgeon, is detached from the "Richmond," and ordered to the Puget Sound Naval Station.

BLAKEMAN, R. S., passed assistant surgeon, is detached from the Naval Training Station, Newport, R. I., and ordered to temporary duty on the "Pensacola."

LEYA, J. F., passed assistant surgeon, is ordered to the Naval Hospital, Newport, R. I., for duty.

MOORE, J. M., passed assistant surgeon, is detached from the Naval Recruiting Rendezvous, Chicago, Ill., October 8, and ordered home to wait orders.

ARNOLD, W. P., passed assistant surgeon, is ordered to the Naval Recruiting Rendezvous, Chicago, Ill., October 8.

BURR, C. R., assistant surgeon, is detached from the Puget Sound Naval Station, and ordered home and to be ready for orders to sea duty.

DICKSON, S. H., surgeon, is detached from the Washington Navy Yard, and ordered to duty at the headquarters of the Marine Corps, Washington, D. C.

HERNDON, C. G., surgeon, is detached from the Naval Museum of Hygiene, Washington, D. C., and ordered to duty at the Washington Navy Yard.

GREEN, E. H., surgeon, is detached from duty at the headquarters of the Marine Corps, Washington, D. C., and ordered to wait orders.

GREEN, E. H., surgeon, is ordered to the "Alabama," October 16.

LIPPITT, T. M., assistant surgeon, is detached from the "Monocacy," and ordered to the Naval Hospital, Yokohama, Japan, for treatment.

Changes in the U. S. Marine-Hospital Service for the week ended October 4, 1900:

STIMPSON, W. G., passed assistant surgeon, is granted 15 days' extension of leave of absence.

HOBBY, W. C., assistant surgeon, is granted leave of absence for 1 month, from October 3.

CORPUS, G. M., assistant surgeon, is relieved from duty at Mullet Key Detention Camp, and directed to proceed to St. Louis, Mo., and report to the medical officer in command, for duty and assignment to quarters.

HUNTER, S. B., acting assistant surgeon, is granted leave of absence for 7 days.

RODMAN, J. C., acting assistant surgeon, is granted leave of absence for 7 days.

RICHARDSON, S. W., hospital steward, upon expiration of leave of absence, to rejoin station at St. Louis, Mo.

Resignations.—Assistant Surgeon **ELMER R. EDSON**, September 22; Acting Assistant Surgeon **A. G. GREENSTREET**, September 30; Hospital Steward **C. F. CROWLEY**, September 4.

Foreign News and Notes.

GREAT BRITAIN.

Charitable Bequest.—Mr. J. R. Jefferies bequeathed the sum of £1,000 for the endowment of a bed in the new Victoria Wing of the East Suffolk and Ipswich Hospital at Ipswich.

New Technical Institute in Belfast.—The city corporation of Belfast has decided to build a new technical school and has selected an admirable site in the center of the city on a portion of the grounds purchased from the Royal Academical Institution.

The Plague in Glasgow.—The number of cases of plague in Belvidere Hospital has slightly increased, the number at present being 24. The "contacts" are much fewer, being only 88. The disease seems to be lurking about Govan, a suburb of Glasgow. Every facility is still being offered the medical profession by the Sanitary Department of getting to know all about the disease. A paper on the plague was read before the Philosophical Society of Glasgow some time ago, by Dr. Alexander R. Ferguson. In it he traced the history of the disease from the third century B.C. onwards to the fourteenth century, when it is estimated that not less than 25,000,000 persons perished.

CONTINENTAL EUROPE.

Physicians Needed.—In Hungary there are thousands of villages and hundreds of small towns without a doctor within 10 miles.

Defective Hearing.—Experiments made by German physicians have shown that about 25% of all school children have some defect in their hearing.

The Hertford Hospital in Paris, which was founded by the late Sir Richard Wallace for the benefit of the sick of British nationality in that city, has now been transferred to the British Government, and a committee of management has been appointed to provide for carrying it on.

Leprosy in Germany.—A report on leprosy in Germany, published by the Imperial Board of Health, states that 22 cases of leprosy were officially known in Prussia at the end of last year, being the same number as in 1898. In most instances the disease was contracted in foreign parts. The Memel district is the only one where the disease is endemic.

The Famous Blind Oculist, Dr. Javal, a member of the Paris Academy of Medicine and director of the Sorbonne Ophthalmologic Laboratory, has been promoted to the highest rank in the French Legion of Honor and decorated with the German Black Eagle. Although he is 60 years old and has been blind for 12 years, he still continues his scientific work.

Leprosy in Portugal.—According to the *Polyclinic* it is estimated by Dr. Falcao in a recent report on leprosy in Portugal that in a population of less than five million, 1,500 are affected. The disease does not restrict itself to any one focus, the cases being scattered about the country and no district being wholly exempt. The majority are, however near the coast.

Cremation in Spain.—A new sanitary law which is now under consideration in the Cortes, having already passed the upper house, removes the ban of illegality which has hitherto, through the influence of the church, rested upon the practice of cremation in Spain. In anticipation of the passage of this law a cremation society has recently been established in that country.—[*Medical Record*.]

Cancer in Germany.—The Prussian Government, in order to make a systematic study of the subject of cancer, has prepared a paper of questions which is distributed to every registered physician requesting him to give his experience in cancer cases. The principal points are whether cancer is hereditary and contagious, whether it is connected with a particular habit, as the alcohol or tobacco habit, or whether it is more prevalent in one district than another.

Women Longer-Lived than Men.—An English weekly magazine says that statistics show that women live longer than men. For instance, in Germany only 413 out of 1,000 males reach the age of 50 years, while more than 500 out of 1,000 females reach that age. In the United States there are 2,583 female to 1,393 male centenarians. In France, of 10 centenarians 7 are women and only 3 men. In the rest of Europe, of 21 centenarians 16 are women.—[*Medical Record*.]

Sanatorium for Tuberculosis in Italy.—The Italian Minister of the Interior has invited competition for a plan of a sanatorium for poor tuberculous patients. He has recently nominated a committee to examine the plans. It includes the names of Professor Bizzozzo of the University of Turin, Professor Durante of Rome, Professor A. de Giovanni of Padua, Professor A. Ballori, director of the Hospitals of Rome, besides those of several well-known architects and engineers.

Association of Anatomists.—The Association des Anatomistes, which was founded last year, held its second meeting in Paris recently. The session was devoted to the discussion of business matters, the Association having for purposes of scientific work joined forces with the Section of Anatomy and of Histology and Embryology of the International Congress of Medicine. The next meeting will be held at Lyons in 1901, the week before Easter, under the presidency of M. Renaud. Among the 32 new members admitted were Professors Waldeyer, His, Golgi, and Eternod.

Foreign University Intelligence.—ATHENS: Dr. Constantin Savas has been appointed to the chair of hygiene and bacteriology. BRESLAU: Dr. Richard Stern has been promoted to an extraordinary professorship of internal medicine. COPENHAGEN: Dr. Oscar Wanscher has been promoted to an extraordinary professorship of medicine. MUNICH: Dr. O. Messerer, extraordinary professor of forensic medicine, has been appointed honorary professor. STRASBURG: Dr. W. A. Freund, the well-known gynecologist, is about to retire from the chair of diseases of women. The names mentioned in connection with the chair are those of Professor Fehling, of Halle, and Professor Frommel, of Erlangen.

Female Students at Zurich.—The number of women attending the University of Zurich, according to the *British Medical Journal*, is steadily increasing. Of 850 students matriculated in the last summer semester there were 214 women. Of these 128 were students of medicine, 58 of philosophy, 21 of natural science, and 11 of law. The ladies appear to give theology a wide berth, but as the total number of students

matriculated in that faculty at Zurich last summer was only 9, it is perhaps hardly fair to conclude that the study of divinity offers no attraction to what the Latin Church calls the "devout female sex." Of the total number of women students 97 are Russians, of whom 84 belong to the medical faculty.

Liman Cure.—At Odessa the Liman cure is becoming popular. The limans are sheets of water that have been isolated from the sea and converted into salt lakes. The waters are concentrated by evaporation and are thought to possess great therapeutic value. The principal salts contained in them are the chlorids of sodium, potassium, and magnesium; calcium sulphate and magnesium, or sodium bromid. A black slimy substance of animal and vegetable composition covers the bottoms of the lakes and contains iodine, bromine, sulphur, sulphuretted hydrogen, and oleic and valerianic acids. Patients bathe either in the open lakes or in baths with the water at different degrees of concentration and temperature. The diseases treated are rickets, scrofula, chronic rheumatic affections, and certain chronic skin diseases.

MISCELLANY.

The court physician to the Ameer of Afghanistan is Miss Lillias Hamilton.

Plague.—It is reported that 5 new cases of plague, with 2 fatalities have occurred in New South Wales.

Yellow fever prevails in Senegal, a French colony in West Africa. The mortality is 86% of those attacked and 15% of the population has perished. The negroes are completely immune.

A Chinese physician's fee ranges from 2 to 5d. This can be accounted for by the fact that any one can practise medicine in China.

The hospital ship *Curthage* will go to Taku via Hong Kong, and the services of 2 military signalers have been sanctioned for the same.

Obituary.—C. P. GANAPATI, of Cuddapah, India, September 22, aged 42.—DR. AYMER, of Bervic, in Kincardineshire.—A. LAMOTROUX, of the Paris Municipal Council.—MORITZ MARCUSE, of Berlin, aged 62.—ABRAHAM KUHN, of Strasburg, aged 63.—FERREIRA DE ARANJO, of Rio de Janeiro, aged 52.—ARTHUR HENRY LEETE, of Talcombe, September 21, aged 33.—MICHAEL RICHARD RYAN, at Hong Kong, September 23, aged 48.—HENRY JAMES HAVILAND, of London, September 22, aged 74.—RICHARD SARELL, of Constantinople, aged 71.

Antityphoid Inoculation.—With reference to the antityphoid inoculations in India last year the *Indian Medical Gazette* publishes some important figures. There were 1,312 cases of typhoid fever among the British troops with 343 deaths, a death-rate of over 25%. The ratio of admissions to total strength was 20.6 per 1000. There were 4,502 inoculations, and among these men there were only 9 deaths from typhoid fever. This gives 0.2% of strength. There were 44 admissions, giving 0.98% of strength. Among the noninoculated in the same corps and at the same stations, of 25,851 men there were 657 cases and 146 deaths, giving the relative percentages of admissions and deaths as 2.54 and 0.56. This is strongly in favor of inoculation.

Plague in India.—The deaths from plague throughout India are still increasing. The recent increase is chiefly in the Mysore State and in the Bombay districts. Mysore city and Poona each show a sharp attack. During the past month 141 deaths have occurred in the latter city. It was at this season that the terrible outbreak occurred last year. The authorities have issued a notice for certain of the inhabitants to vacate their houses within 4 days and stay in the health camp. Dead rats have been found lately in many places. Affected places are disinfected, but segregation has been done away with and there is no compulsory inspection. In Bombay and Calcutta the amount of plague continues about the same, Calcutta reporting 85 deaths and Bombay city 49. Cholera is decreasing nearly everywhere.

1.—H. MacNaughton Jones, after reviewing at length the correlation between sexual function, insanity and crime, reaches the following conclusions: 1. Functional disorders of ovulation are frequently attended by mental aberration, and in a proportion of cases originate the mental disturbance. The same remark applies to disorders of ovulation which have a pathologic cause. 2. In the great majority of such cases, the nervous disturbance is of the neurasthenic character, and is associated with various visceral or other neuroses. In only a small proportion does the alienation assume so grave a type as melancholia, mania, or dementia. 3. Where in an insane person, ovulation and its external manifestation, the menstrual discharge, are erratic or absent, the erraticism or absence may be a consequence of the general and insane condition, and not a causal factor in its production; but under any circumstances such abnormal menstruation appears to have an aggravating effect on the insanity, and there is sufficient evidence to support the view that when such irregularity—especially if it be due to a pathologic cause—exists, it should be treated therapeutically or by operative measures. 4. The question of a gynecologic examination of an insane woman must be a matter for the discretion of the psychologist, influenced by the gynecologic view as to its expediency from the signs and symptoms present in the sexual organs. For many reasons, as a universal practice, with our present knowledge it is not advisable. 5. Sufficient evidence is now advanced to justify the removal of the adnexa or uterus in insane women, when there are gross lesions of the former or tumors of the latter. Here, again, such operation must be advised according to the psychologic condition of the patient and the type of her insanity. 6. From a mass of evidence, including some of the largest experiences in Europe, Canada, and America, it does not appear that there is in healthfully-minded women, who suffer from diseases of the genitalia, any special risk of post-operative insanity. On the other hand, if there be a psycho-

pathic predisposition, which had existed prior to and independently of the sexual disease, there is in such cases a larger percentage of postoperative mental disturbance than follows other operations. In such women the prudence of a radical operation may have to be carefully discussed. The postoperative mental effect does not appear generally to be of a serious or permanent nature. 7. It may be generally affirmed that when mental disease of a graver type follows upon sexual disorder there has been in the woman affected an underlying and often unrecognized psychopathic predisposition; the disorder of the menstruation or the disease in the genitalia completing the chain of the vicious circle needful for the final manifestation of the mental condition. 8. The relation of aberrant sexual function or a disorder of menstruation to any criminal act ought to be taken into consideration in determining the responsibility of the woman. [W.K.]

2.—The clinical history of epileptic insanity in its early stages in the adult is that of fits for several years; then, without warning, after a fit or a first succession of fits, mental symptoms show themselves, slight confusion of ideas or temporary loss of memory, or the performance unconsciously of some purposive act. These slight mental disturbances later develop into maniacal paroxysms of an impulsive, homicidal, or generally dangerous character. In some cases hallucinations of hearing supervene upon the post-epileptic phenomena and give rise to temporary delusions. For a considerable period in the course of the disease the mental faculties remain quite clear between the attacks, but gradually dementia sets in, preceded in its early stages by irritability of temper, confusion of ideas, restlessness, and querulousness. In other cases, before the onset of dementia the paroxysms of convulsions disappear, to be replaced by periodic maniacal outbursts. The histories of 6 cases are given which corroborate the statement that the periodic paroxysms of convulsions may be replaced by periodic maniacal attacks. The histories of 5 cases of recurrent mania are appended. These cases have hitherto been considered a distinct form of insanity; but they appear to Pasmore similar to those maniacal states associated with epilepsy. The features that are characteristic of epilepsy and epileptic insanity are: 1. That the disease is markedly hereditary. 2. That it is periodic in character. 3. That between the attacks the patient is quite *compos mentis* and it is only after varying periods that dementia supervenes. 4. That maniacal attacks precede and succeed the epileptic convulsions. 5. That these attacks alternate at times with the convulsive seizures. 6. That they might replace them. 7. That the maniacal attacks have certain definite clinical features. The features that are characteristic of epilepsy and insanity as we know it, and those that are characteristic of recurrent mania, appear to have many points in common: 1. Heredity seems to play a prominent part in both and a history of epilepsy appears common to both. 2. They are both periodic in character. 3. Between the attacks the patients show the same proclivities to well-being. Epilepsy might alternate with maniacal symptoms, and mania may precede or follow epilepsy. 5. Maniacal attacks might entirely replace the epileptic state, especially when that is of the *petit mal* type. 6. The mania associated with ordinary epileptic insanity, and that known as recurrent mania, showed marked similarity in their clinical symptoms. For the above reasons recurrent mania is considered to be an epilepsy of a psychic type, therefore it is proposed to term it *psychic epilepsy* or *epileptoid mania*. For clinical purposes, therefore, we may classify the insanities associated with epilepsy into: 1. Congenital, including (a) idiocy (epileptic), (b) imbecility (epileptic). 2. Idiopathic epileptic insanity, the ordinary insanity of epilepsy as met with in the adult. 3. Hysteroepileptic insanity, found chiefly in young girls about the age of puberty. 4. Psychoepileptic insanity; (a) recurrent or epileptic mania; (b) *amnesia transitoria* and *epilepsie larvée*. [J.M.S.]

3.—The last census gave one lead-worker to every 58 of the population of England and Wales; taking the proportion of lead-workers to the population to be unchanged, there should be 18 of this class in Claybury. There are, however, among the 1,959 male patients 35 which suggest *prima facie* that the occupation of this class may be a contributory factor in the causation of insanity. That lead has a far-reaching and subtle deleterious influence upon the

nervous system is undoubted. The use of virgin lead is not common as a cause of lead-poisoning. The danger with the metal begins with the smelting; the fumes given off by the molten mass, being poisonous, are absorbed by the mucous membranes, principally of the mouth and nostrils. The skin when intact is stated to be a doubtful source of poisoning, although chronic lead poisoning has followed the use of cosmetics and hair dyes. When absorbed, the lead is said to be stored mainly in the liver, kidneys, and brain. Arterial degeneration, renal disease, anemia, privation, and drink predispose to **lead-poisoning and insanity**. The young are more predisposed, especially women. Out of 133 cases who, from the nature of their work, were liable to lead-impregnation, the following is an analysis of the mental condition: mania, 37; melancholia, 33; dementia, 19; dementia with epilepsy, 10; dementia with general paralysis, 24; general paralysis, 7; alcoholic mania, 3. Jones finds (1) that lead-poisoning is a contributory factor in the causation of insanity, and that in lead-workers there is a higher average number of general paralytics than in others of the population; (2) that there is a tendency in such cases to cardiac, renal, and arterial degeneration with complications due to syncopal or epileptiform fits; (3) that most cases present marked signs of anemia and ill health with unsteadiness of gait and general impairment of muscular strength and very frequently a history of temporary failing vision; (4) that the mental symptoms may be grouped among one or other of the following varieties: (a) those in the nature of a toxemia with sensory disturbances, which tend rapidly to get well; (b) those with hallucinations of sight and hearing, more chronic in their nature, that may be irrecoverable; (c) those resembling general paralysis with tremors, increased kneejerks, incoördination, and accompanied with listlessness amounting to profound dementia which tends to get well; (5) that in most lead cases presenting mental symptoms the tendency is to recovery, unless the patient dies early. The most characteristic mental symptoms of lead-impregnation are affections of memory, confusion, incoherence, headache, want of power to fix and sustain the attention. Depression, irritability, and suspicion are more frequent than active, restless excitement and noisy, rambling delirium. Visual and auditory illusions with terrors are frequent, but there is no reaction and resentment; fits occur in 36% of cases. The treatment of the cases reported has been mainly expectant. There is a tabulated summary of 19 cases of general paralysis. [J.M.S.]

4.—By **acute delirious mania** is meant a condition of delirium associated with a group of bodily symptoms of a typhoid type. There is extreme restlessness and weakness, feeble circulation, a dry, brown tongue, sordes of lips and teeth, and generally, but not always, a slight increase of temperature; sometimes the above group of mental and bodily symptoms appear in a previously healthy subject; at other times, and probably more frequently, they are superimposed on an existing condition of insanity. There are 3 divisions into which cases of acute delirious mania fall: (1) Those of alcoholic origin; (2) those of septic origin; and (3) those in which we are not able at present to identify any particular poison as the cause. The latter is due to a poison generated within the organism,—it is autotoxic. In a female, aged 43 years, the disease began 6 weeks prior to admission to hospital with symptoms similar to those noted on admission; her mother was "strange in her mind," a brother was a drunkard and committed suicide. When admitted the axillary temperature was below 95°; pupils were contracted but would react to light; pulse 80, tongue red and sticky at the sides, dirty-brown with yellow fur down center; lips, teeth, and palate covered with dirty slime; bladder distended; general condition very feeble. The patient lies and chatters to herself, smiles and calls out, pays no heed whatever to questions, mouths and waves her hands about, is at times noisy. She passed a large quantity of urine in the night and did not sleep; fell asleep at midday the following day and slept till 4.30 P.M., when a change was noted; she was breathing noisily and apparently unconscious; next day she was quite lively, and, when questioned as to her health, replied, "Quite well, I thank you." Twelve days later the patient died, 18 days after admission. Necropsy showed no gross lesions. In certain cases of acute delirious mania, a fairly constant change is met with in certain areas of the brain. The giant cells of the ascending frontal convolution present the most marked alterations. When stained in toluidin-blue and pressed out in Far-

rant solution or in glycerin an enormous accumulation of yellow pigment is found. The cell is generally plump and big with numerous dendrites of the usual bulk and configuration. Sometimes there is manifest crumbling of the Nissl bodies, both in the cell bodies and in the dendrites. The cells and their processes are not fragile, and probably not altered in shape. The axis cylinder stains very slightly deeper than usual. As a rule the color in the cell is so deep that the nucleus and even the nucleolus are obscured. A common feature in all sections made from the cases was a large number of free nuclei within the pericellular and perivascular spaces which were seen in all layers of the cortex. The giant-cells in section appear very much more altered than when studied in films. They are shrunken and distorted; often only an irregular, deeply-stained, pigmented mass is seen lying within a large pericellular space, and with only 1 or 2, perhaps fractured, processes coming off from it. The fracturing of the dendrites is obviously an artificial process, but it has a pathologic significance. It was seen in films that the cell retains its usual size and shape, but when subjected to dehydrating agents it appears as a shrunken, deformed mass. This seems to indicate that in this disorder the substance of the cell-body and its processes is of a more fluid character than usual; hence the greater shrinking that it undergoes when treated with alcohol. Of course this shrinking pulls the cell-body away from its dendrites, which are held by the matrix of the cortex, and thus causes them to fracture. In sections stained with osmic acid we generally find numerous tangential fibers in the ascending frontal region. By osmic acid a fatty degeneration of the nerve-cells of the second and outer part of the third layer can also be demonstrated. Fatty degeneration of the liver-cells is a very common occurrence. It is believed that all forms of acute delirious mania are of a toxic origin, but whilst some are obviously caused by the introduction of a poison from without, namely alcohol, others are caused by the absorption of septic material, whilst a third class are due to autointoxication, probably as a result of perverted metabolism, which the disordered nervous system is very likely the cause of. The fact that in these acute cases, occurring as they do in the prime of life, we almost invariably meet with fatty degeneration of the liver, an organ one of whose functions is most probably to prevent the introduction into the system of poisonous intestinal products, is in corroboration of this idea. [J.M.S.]

5.—Turner's experience in the **treatment of epileptics in colonies** is entirely limited to the working of this system, as seen at the farm-colony at Chalfont St. Peter. Provision should be made in all colonies for the education of epileptic children. The principles which have guided the author in the management of adult sane epileptics in the colony are: (a) The removal of the epileptic from town or city environment, including his removal from the sometimes unsatisfactory influence of the domestic circle; (b) regular and congenial employment in garden, fields, orchards, or workshops, under the supervision of capable persons; (c) a well-ordered and regular mode of life, with avoidance of excitement and abstinence from alcoholic liquors; (d) abundance of nourishment of a simple character; (e) the reduction of medicinal remedies to a minimal amount. The effect of the practical application of these principles upon the number and severity of the seizures, and upon general and mental conditions, may be briefly summarized: (a) The frequency of the fits is usually considerably diminished for a period after admission, a change which may be ascribed to the effects of improved hygienic surroundings. In a minority there is a temporary increase in frequency, probably due to a diminution of the potassium bromid, with which many are saturated on arrival. In the majority, the average frequency of the seizures is soon obtained. Of those who have been with them for the 6 years of the colony's existence, it may be said that they maintain a surprisingly constant average, both in the frequency and the severity of their seizures. (b) In the majority of cases an amelioration in the severity of the attacks has been seen; in a minority no material alteration is observed, while in a few there has been a distinct increase in severity. (c) In a very small minority there has been a steady downward tendency towards dementia, apparently the natural course of the disease in these cases, as it was associated with increased severity and frequency of the fits. In the great majority of cases no such mental deterioration has been observed. The average mental state is very constant. Many of the colonists are

capable of work requiring individual alertness and tact, while most are able to do good work under supervision. (d) It is scarcely necessary to do more than mention that under the influence of good food, regular meals, and improved hygienic circumstances, the general physical state undergoes material improvement. But apart from the influence which the colony system has as a remedial agent upon the duration or course of epilepsy, it has also to be regarded as of immense utilitarian value. It affords the means of giving employment to a class of the community who have great difficulty in finding work on account of their peculiar malady; it provides that kind of work which is most suitable for the slow, torpid nervous system associated with this disease; as the work usually performed is scheduled and under direct supervision, the nonimaginative and debilitated have as good a chance of success as the alert and imaginative, and that which is perhaps of most value lies in the general moral effect which the system exerts upon the individual colonists. If interest is taken in his work, in his mode of life, and in his amusement, the confirmed epileptic is capable of becoming quite a useful citizen. At the commencement of epilepsy, usually during puberty or in early adolescent life, the brain should receive that all-round rest which can only be obtained by withdrawing the patient from school or college, by lessening to the utmost the more severe forms of exercise so agreeable to the young, and preferably also by removing him temporarily from social intercourse with those of his own age. In the majority of cases which improve or get better the cure should only be spoken of in relative terms, for it has to be borne in mind that long intervals amounting to several years may elapse between seizures, and also that a dose of bromid at bedtime may keep down the explosive tendency for many years. Corner was much struck by the great waste of money and labor entailed by sending epileptics and trained high-grade imbeciles home after the period of their training since the value of their work when at home is very little—about 10% of that done under supervision. The speaker would divide the cases into 3 classes: (1) Those who when trained require supervision in a home; (2) those who might be made well enough to earn a livelihood in the outside world; and (3) an intermediate class who could be made practically self-supporting in suitable surroundings. Andriezen urged the importance of classification in obtaining practical results. There are sane epileptics in whom cure is impossible because the lesions begin in intrauterine life. There are idiots and imbeciles of low, medium, and high grades; there are epileptics with grave mental perversion and criminal instincts (epileptic paraphrenia), and finally there are epileptic phrenopaths in whom the epilepsy was a late symptom in life, and might often be an acquired disease. The low-grade epileptic idiots and imbeciles require the provision of custodial institutions, cheap, and managed on a large scale. They are uneducable and unproductive patients. The epileptic imbecile of higher grade and the feeble-minded epileptic require farming and industrial institutions. They are educable and trainable, and can with proper supervision be made to a great extent self-supporting, though if allowed to be in the world at large they cannot earn enough to live, as their labor has too little market value. They also tend to deteriorate and to perpetuate vice and crime, and to breed a bad progeny if living at large, and this should be prevented. Sane epileptics can be treated at home or in hospital as out-patients, according to their means. Epileptics with tendencies to violence, brutal impulsiveness, murder, and postepileptic automatism of a dangerous kind require sequestration and careful watching. Cases of psychical epilepsy proper may be associated with scholarly ability and even artistic talent. [J.M.S.]

6.—The article is only of interest to those practising under the lunacy laws of England. [J.M.S.]

7.—In order to determine the therapeutic value of animal extracts in mental disease, the fallacy of calling a "recovery" what may become only a temporary remission of symptoms; attributing to an extract mental recovery, improvement, or retrogression when these effects are in reality due to the natural course of the disease; and of ascribing to an extract benefit which is really attributable to psychotherapeutics in some form or another must be considered. To ascertain the pharmacologic actions of animal extracts in the insane, one is not justified in coming to final conclusions unless they have been obtained from various

animals, made up in different pharmaceutic forms, and administered by the stomach, subcutaneously or otherwise. The author administered thyroid extract in 130 cases of chronic or incurable insanity, 85 females and 45 males. There were 160 separate administrations of the drug; of these 120 were with large doses, 10 with moderate doses, 20 with small doses, and 10 with commencing small doses, gradually increased to moderate or large. In the case of large doses the equivalent of a sheep's gland was given daily for a week; pyrexia was absent in 15%, present in 85%. Loss of weight was constant in all cases weighed within 4 days of the cessation of the drug, and amounting on an average to 6 pounds. The loss was usually followed by a gain in weight, which did not set in till after the cessation of the drug. Increased perspiration and hyperemia, followed by desquamation and a healthier appearance of the skin, were common. Diminution of the hemoglobin was the most frequent change noted in the blood; decrease of the red blood-corpuscles came next in frequency, and a slight degree of leukocytosis was often present. The thyroid gland and the spleen were not apparently affected in size. Sensory symptoms in the form of pains and tinglings in various parts were common. Motor tremors and ultimately weakness were also common. The pulse was invariably increased in rate, usually by 30 or 40 beats, and became softer, and finally it became weak and irregular, and gave the signal to stop the drug in the majority of cases. Thyroid was well borne by patients with valvular disease of the heart, but very badly by those with fatty heart-disease. Pulse tracings showed distinct evidence of diminished tension. The respirations were increased constantly, usually by 6 per minute. The appetite was usually diminished during the drug, but considerably increased afterwards. Thirst was commonly increased toward the end of the treatment. In 25% of cases thyroid dyspepsia occurred, necessitating the stopping of the drug in 10%, the dyspepsia is of the nature of a catarrhal irritation produced by iodothylin, possibly by its iodine. Menstruation was frequently more profuse than usual during treatment. The daily amount of urine was usually increased, slight transitory albuminuria was produced in 10% of the cases. Total dissolved solids were markedly increased, the increase amounting generally to $\frac{1}{4}$ of the previous average daily quantity, the urea, similarly, was much increased, usually by $\frac{1}{4}$ of its previous quantity; the phosphoric acid was also markedly increased, especially during the earlier period of the treatment, the increase amounting usually to $\frac{1}{3}$ of its former average level. The increased phosphoric acid is probably in part derived from the metabolism of the nucleoprotein of the dry extract. Moderate doses, equivalent to $\frac{1}{4}$ of a sheep's gland, continued daily for 2 weeks, were given in 10 cases; and in 20 cases small doses were given, equivalent to from $\frac{1}{4}$ to $\frac{1}{16}$ of a gland. In these cases the physiologic effects produced were essentially similar in kind to those produced by large doses, differing usually only in degree. The preceding phenomena indicate that thyroid extract in the insane acts as a powerful metabolic stimulant, or more accurately as a katabolic stimulant. Small and moderate doses were tolerated well by all. In the case of large doses, the drug was borne badly by those under 20 years, and much more so by those over 60, the former showing special tendency to lose much weight, the latter to exhibit failure of the pulse. Out of 130 patients treated, 12 recovered, 29 were improved, and 89 were unimproved. Experience indicates that the thyroid treatment of insanity is more efficacious in women than in men, as in a table of cases it was seen that the best all-round results were obtained in the insanities connected with childbearing. Parathyroid extract was administered to 3 female patients. The pharmacologic effects were practically negative, with the exception of a slight increase in pulse-tension. The therapeutic results of parathyroid in the 3 cases were negative. Thymus extract was administered in 2 cases of insanity, both males. One a case of melancholia of resistive type and the other a case of general paralysis. The doses given in both cases varied from 60 grains on the first day to 90 grains on the second day, to 120 grains on the third day, continued for a fortnight, each patient receiving in all during this period 1,590 grains of the dry extract. The temperature rose in both cases and there was a loss in weight of 6 pounds in the general paralytic and of 5 pounds in the melancholic during the first week of the drug; but during the second week both patients regained what they had lost

and the melancholic gained an additional 5 pounds after the cessation of the treatment. No mental improvement was noted in either case, but in both there was distinct physical improvement. **Pituitary extract** was administered in 4 cases of insanity, 3 males and 1 female. The daily doses employed varied from 24 to 72 grains, and were continued for from 1 to 2 weeks. The temperature rose in 2 cases and was unaffected in the other 2. Three of the patients lost from 1 to 2 pounds each during the first week of treatment, but all 4 ultimately gained in weight. The pulse in the 2 general paralytics became distinctly stronger toward the end of treatment. The bowels became more and more regular in action during the second week in one case. All patients were unimproved mentally, but the 2 general paralytics were improved physically. **Cerebral extract** was administered in 19 cases of insanity; 16 women and 3 men, the daily doses varied from 15 to 90 grains. The temperature in $\frac{1}{2}$ the cases was subfebrile; in the others it was unaffected; weight was unaffected in all except 4 cases, in which there was a loss followed by a gain which set in either during the later course of the drug or afterwards; 4 patients became more excitable, talkative and impulsive; respirations, except in one case, were increased; nausea and vomiting were noted in 2 cases, diarrhea in 1. Menstruation appeared "irregularly" during treatment in one case, and in another case, a puerperal patient who had been amenorrheic ever since her confinement 9 months before, it appeared on the seventh day after the cessation of treatment. In the urine there was a slight increase in the total solids and in the urea. Dry brain extract tends to produce more particularly pyrexia and increase in urinary solids, indicating a slight increase in proteid metabolism, which is possibly due to the richness of nucleoproteid and nitrogenous matter in the extract. Of 19 cases reported, 14 were unimproved, 3 improved (all females), and 2 recovered. Those who recovered or improved mentally were also benefited physically. **Choroid plexus abstract** was administered in 2 male general paralytics, the daily doses varied from 10 to 50 grains. There were no pharmacologic effects, except a temporary slight loss in weight in one patient. Therapeutically the results were negative. **Suprarenal extract** was administered by the stomach in 4 cases of insanity, the daily doses varied from 15 to 120 grains. The temperature was unaffected in 3 cases and lowered in a fourth. The weight increased in 2 cases, was unaffected in one, decreased slightly in one, but regained on cessation of the drug. The blood was unaffected in one case, but in 2 cases the hemoglobin was slightly increased, the red corpuscles being slightly increased in the one and slightly diminished in the other. The pulse diminished in frequency in 3 cases and blood-pressure was increased. The respirations were slightly diminished in one case. The total solids, urea, and phosphoric acid were slightly diminished. The mental state in 3 cases was not changed; in one case there was a distinct cessation of excitement, during treatment. **Dry splenic extract** was administered in 2 female cases, the daily dose varied from 15 to 90 grains. There was evidence of a slight stimulation of proteid katabolism, followed by an anabolic reaction, effects in no way specific, but accountable for by the nucleoproteid in the dry extract. Therapeutically, both patients, adolescent and climacteric melancholics, showed a slight temporary improvement, physically and mentally, but soon afterwards continued much the same as before treatment. **Dry orchitic extract** was administered by the stomach in 8 cases of insanity, the daily doses varying from 15 to 120 grains. The temperature was continuously raised in 5 cases. Weight in 4 cases was diminished; the loss in weight was followed by a gain, which usually set in before the drug was stopped. In 2 cases there was a distinct increase in the water, total solids, urea, and especially in the phosphoric acid of the urine; in the other cases the increase in phosphates was usually present though less marked. Menstruation was unusually and severely profuse in 1 female adolescent, though occurring at the usual period; mental excitement occurred in 2 general paralytics, in one amounting to temporary acute mania, 3 patients were slightly improved mentally; the other patients were unimproved mentally, but 2 of them, as well as the 3 previous cases, were improved physically. **Dry ovarian extract** was administered in 36 female cases, the daily doses varying from

15 to 120 grains. Temperature was raised continuously in $\frac{1}{2}$ of the patients. The weight was mostly unaffected, sometimes increased by 2 to 3 pounds, but often temporarily decreased by 4 to 5 pounds, the loss in these cases being usually followed by a gain. The hemoglobin and red corpuscles were slightly increased or slightly decreased in a few cases. Menstruation was occasionally more profuse than usual at the regular periods, and in 5 cases it occurred irregularly during treatment, and in one case it reappeared 14 days after the cessation of the treatment, having been in abeyance for 8 months. The urine showed a slight increase in total solids, affecting the phosphates more than the urea. Mental excitement occurred in $\frac{1}{2}$ of the cases, and an increase of vigor occurred distinctly in 2 prematurely senile cases. Two patients made a recovery long after treatment, and probably independent of it; 4 cases mainly stuporous were temporarily improved, the others were unimproved. **Uterine extract** was administered in a case of puerperal mania which had subsided in severity, but was becoming stationary and relapsing in tendency. The therapeutic effects of uterine extract were negative, but the patient made a good recovery two months later, when menstruation became reestablished. **Mammary extract** was administered in 2 cases, one a puerperal maniac, who had become stuporous and stationary, and the other a lactational, still in the acute stage, the drug appeared to cause no change in the blood, pulse, respirations, or in the mental condition in either case. Both patients, however, eventually recovered. These investigations lead to the conclusion that those animal extracts that consist mainly of simple proteids and albuminoids, merely have a dietetic value; but that those animal extracts that are rich in nucleins and nucleoproteids produce, when given by the stomach in sufficiently large doses, a temporary stimulation of cell-katabolism with a subsequent anabolic reaction, this being evidenced by the common increase of the water, total solids, urea, and phosphoric (and uric?) acid in the urine; by the general tendency to a subfebrile pyrexia; and, perhaps most important of all, by the initial loss in weight, followed by a gain. This initial katabolic stimulation, with its resultant anabolic reaction, is the explanation of the physical improvement or "tonic effect" which occurs in a fair proportion of cases, and which, if pronounced, may be accompanied by mental improvement, and even by mental recovery. In this sense, therefore, these substances may be termed metabolic tonics, and it is probable that in the living body those organs which are naturally rich in nucleins and nucleoproteids produce, in virtue of the metabolism of these substances, similar distant "tonic" effects upon the general cell-metabolism. In the administration of animal extracts in diseases generally, it is of the utmost importance to recognize the fact that many of them (apparently those rich in nucleins and nucleoproteids) may produce this tonic effect. Apart from the general tonic effect upon cell-metabolism, it is extremely doubtful whether each organ possesses a specific internal secretion in the sense intended by Brown Séquard. Some organs probably have such an "internal secretion;" for example, the active principle (sphingogenin) of the suprarenals which powerfully increases muscular contraction and apparently diminishes tissue oxidation. So also the thyroid has an active principle (iodothylin), whose specific effect is to stimulate cell-katabolism or tissue oxidation, for in this respect thyroid extract stands far above all others, and when it is administered in large doses the anabolic reaction never sets in until after the cessation of the drug, whereas in the case of all the other "metabolic" extracts which have been used an anabolic rebound generally sets in during the continuance of the drug. [J.M.S.]

S.—Whitwell reports a case which appears to present a disproportionate evolution between the cardiovascular and nervous systems; and in the case of the latter, though sufficient blood supply was apparently present to carry on the vital organic change of mere growth, the progressive cytoplasmic changes and complex internuncial communications representing the educative intellectual life of the individual failed to be evolved. A second class of cases is one in which congenital or early infantile heart disease of serious type is present. In 2 reported cases the condition of puberty or early adolescence remains as almost a fixed one, and to this basis in each case is added its special individual symptom coloring varying with education, heredity, and environ-

ments. These, it appears, are practically cases of pubertal or early adolescent insanity, existing at a period other than, and later than usual, as a result of serious congenital or early-acquired valvular disease of the heart, the permanent condition being one of physical and psychical immaturity. A still more common set of psychic symptoms to be found in connection with abnormal cardiac conditions is met with in some cases of mitral disease, especially stenosis, more frequently and more typically occurring in females. A case is reported that would be commonly known in an asylum as either mania or melancholia. The condition is merely the symptom reflex of a condition of irritable weakness. The cardiac condition associated with certain cases of seility appears to be one of asthenia, with its associated erethism, and the balance of evidence would appear to suggest the view that the cardiac was the primary condition, the mental symptoms being but an exaggeration of the mental condition typically present in acute cardiac asthenia. [J.M.S.]

9.—In states of acute mania the blood-pressure is low, whereas in the majority of cases of melancholia the blood-pressure is raised; in other words, with the affective disorders of the mind there is an alteration in the tonicity of the vasomotor system. It was hoped that in some way the data presented by Craig might assist in indicating the line of treatment likely to be suitable in different types of disorders, but the weight of evidence goes to show that altered blood-pressure is more a symptom in, than a cause of, mental disorder. All evidence at the present time shows that the low blood-pressure indicates restlessness. [J.M.S.]

10.—Smith has met with no case in which it could be said that there was a characteristic polyneuritic psychosis apart from alcoholism. [J.M.S.]

11.—Muscle is in part "autotonic," and in part dependent for its tonus on the nervous system. Muscle tone is dependent on every portion of the reflex arc, and loss of either centripetal or centrifugal nerve-impulses profoundly modify it. There is a seeming want of accordance between physiologists and clinicians as to the effect of transverse spinal lesions, the former stating that transection (after the disappearance of shock) leaves the reflexes increased, whilst the latter find that complete transverse crush of the cord produces the opposite effect. Halliburton believes that the difference of results obtained by physiologic experiments on animals and clinical observations on man with regard to the effect of total transverse lesions of the cord on reflex action are due partly to the fact that a crushing lesion is a different thing from a clean cut with a knife, for no doubt a considerable area of gray matter is injured also. It may also be that the gray matter in man is particularly susceptible to shock. Muskens said that the relation which undeniably existed between muscular tonus and the tendon phenomena was not a direct one. Although as a rule the sharpness of the tendon reaction increased with increase in tone of the muscles concerned, yet in many instances exaggeration of tendon phenomena accompanied markedly subnormal muscular tonus. He regards tendon phenomena as being dependent on the nutrition and irritability of the muscle-fibers, the passive tension of the muscle, and the muscular tonus. Apart from the muscle itself, other factors concerned are nerve impulses from the cerebrum, the cerebellum, and the spinal cord. He does not regard tendon phenomena as reflex, but rather as directly excited by mechanical stimulation. [J.M.S.]

12.—In the cat and monkey the author has previously shown that the abolition of the afferent impulses which normally impinge upon the anterior cornual cells through the posterior roots, is accompanied by the change known as chromatolysis. This fact, in conjunction with the law established by Nissl, indicates that the normal life of the cell depends not only on the integrity of the parts of its own neuron, but on those which are immediately related to it. Complete section of the spinal cord is accompanied first by chromatolysis, and later by atrophy of the cells of Clarke's column, while the cells of the anterior horn remain intact even after a period of 150 days. Division of an anterior root is followed by chromatolysis in most of the cells at the outer part of the cord, whilst those situated most internally remain normal. This observation supports the contention of von Lenhossek that they are not root-cells, but commissural in nature. Speaking generally of the value of the Nissl method, the author has never found the condition of chromatolysis except

in morbid conditions, and hence he is convinced of the significance of its presence in cells. At the same time the reaction appears to be subject to certain limitations; it varies with the species of animal, with its age, and with the nature of the interference produced. He does not think it can be regarded as absolutely trustworthy in attempts, therefore, to delimitate nuclei. [J.M.S.]

13.—In birds, when uric acid is the most important end-product of nitrogenous disintegration, the source has been given a secondary place. The author fed and injected subcutaneously nucleins, nucleic acid, and alloxur bases to geese, turkeys, ducks, and hens, and found that on giving the 2 first mentioned substances there is a more distinct increase of uric acid than in mammals, and may be as distinct an increase in phosphoric acid. The rise in the excretion of P_2O_5 is greater than could be accounted for from the organically formed phosphorus absorbed, and one gets a leukocytosis more or less of the same type as in mammals. The blood of a hen under the influence of nucleic acid shows a much higher percentage of P_2O_5 than that of a normal one. The author cannot speak at present of intracellular changes in the case of birds after nucleic acid, nor of the effects of the alloxur bases, but there seems to be little doubt that the formation of uric acid from nuclear disintegration may be an important one in birds as well as in mammals. [J.M.S.]

14.—Anderson discusses the mode of entrance of atmospheric air into the pulmonary lobules and infundibula. Experiments suggested that the rate of entrance of air into the alveoli was exceedingly slow and hence, that the alternate rarefaction and compression of the alveolar air was by no means inconsiderable. [J.M.S.]

15.—Pembrey, Passmore, and Clayton report 4 cases of heat-stroke. The observations show that after the "heat-stroke" the skin was dry and hot, and there were no signs of sweat. The surface temperature was 3.5° to 5.5° F. above the normal temperature of the skin. The deep temperatures were 103° and 99.8° . One of the cases was one of so-called "heat exhaustion" with profuse sweating, collapse, and subnormal temperature 95° . Mitral incompetence was present, and possibly dates from the "heat-stroke." The observations are too few and incomplete to justify conclusions or theories, but they show that the cases of so-called "heat-stroke" are complex and obscure. With a high internal temperature and no sweating the temperature of the skin becomes abnormally high, and the body is warmed throughout. The heart appears to be affected, or it may be that men with weak hearts are more readily affected by the heat. There may be profuse sweating, with collapse and subnormal temperature. [J.M.S.]

16.—In a series of experiments carried out on dogs by Thompson, it was shown that ether caused an increase in the amount of urine secreted and a slight increase in the total quantity of nitrogen, whereas chloroform caused a diminution in the amount of urine and in the amount of nitrogen contained therein. Mixtures of these drugs caused very variable results. [G.B.W.]

17.—Bixton and Levy have carried out a research on the effect of ether on the kidneys, including experiments on animals and evidence gathered from clinical statistics. They do not believe that an initial rise of the blood pressure is a constant effect of ether-narcosis, and also take exception to the statement of Kemp and Johnson that a suppression of urinary secretion begins in the early stages of the narcosis and is due to a "specific ether effect," i. e., an ischemia of the parenchyma of the kidney, though it sometimes develops later on in the narcosis. They believe that the decrease in the amount of urine secreted during the anesthesia is due rather to the depletion of the watery constituents of the blood of patient preparatory to and after the operation by purging, vomiting and abstinence from fluids. They also claim that there is little evidence tending to show that ether exerts any deleterious influence on the kidney parenchyma. The albumin found in the urine of some dogs after ether, narcosis is due rather to the "specific effect" than to any pathologic change in the organ. [We are inclined to discredit the value of the above results, as they seem so contrary to generally adopted opinion of the influence of ether on the normal kidney. It has been distinctly demonstrated that ether is capable of producing in dogs and rabbits a temporary cloudy swelling of the parenchyma of this organ even when narcosis has lasted but a short while, and although this con-

dition does not permanently injure the kidney, we can scarcely bring ourselves to believe that the albumin sometimes found in the urine of dogs after etherization is due to an ischemia of that organ. Besides, ether does not produce an ischemia, but a marked congestion of the parenchyma. G.B.W.]

20.—Waller has invented an instrument which he calls a **digital sphymograph**. It consists of a rather stiff fixed spring and a movable support between which the tip of a finger is inserted; the movements imparted to the spring by the pulsatile elevations of the finger nail are magnified about 50 times by the lever, and, if desired, may be recorded on a smoked cylinder or glass plate. [J.M.S.]

21.—After an investigation of the changes in volume of the submaxillary gland accompanying secretion Bunch draws the following conclusions: 1. Changes in volume of the submaxillary gland may be brought about both by variations in the flow of blood to the gland and of secretion from the gland. 2. Cardiac inhibition, whether brought about by vagus stimulation or by drugs, is followed by shrinkage of the gland. When this shrinkage is brought about by vagus stimulation, it is followed after the stimulus has been removed by an after-dilation of the gland. 3. Stimulation of the chorda tympani causes diminution in the volume of the submaxillary gland, followed by an after-dilation. 4. After the administration of a dose of atropin sufficient to paralyze the secretory fibers of the chorda, excitation of the chorda causes dilation of the submaxillary gland. 5. Sympathetic stimulation causes shrinkage of the gland, and a maximum effect is obtained when the chorda has previously been subjected to repeated excitation. 6. Continuous stimulation of the chorda after blockage of the gland duct causes a maximum dilation of the gland. 7. The amount of secretion poured out as a result of chorda stimulation is chiefly if not altogether derived from the fluid in the gland cells, or, at least, from the extravascular portions of the gland. [J.M.S.]

1.—In the treatment of eczema, an iron and magnesia mixture with a little nux vomica, or an alkaline bitter mixture with an aperient if necessary, and regulation of the diet as far as possible, should be administered. In acute inflamed cases ointments which contain 10 grains of acetate of lead, 10 grains of calomel, 20 grains of oxid of zinc, 20 grains of ointment of nitrate of mercury, and 1 ounce of vaseline can be used. Occasionally Lassar's paste, 3 drams each of zinc oxid and starch, 10 grains of salicylic acid and 1 ounce of vaseline may be necessary. When the weeping and inflammation are excessive a powder thickly dusted on is sometimes effective, half an ounce of starch, 2 drams of oxid of zinc, and 1 dram of powdered borax or boric acid. The zinc-gelatin treatment consists of half an ounce of gelatin, 3 drams of oxid of zinc, 1 ounce of water, half an ounce of glycerin, and 10 minims of ichthyol can be added. The mass melted in a glue-pot and painted over the diseased area, forms an elastic, protective, and soothing covering. In all cases, immediately before applying any of the above, the affected parts should be well bathed with a very dilute antiseptic lotion. If preferred a lotion containing half a dram of creolin to a pint of

soft boiled water can be used. In dry eczema and where there is but little inflammation tar ointments are usually very efficacious. Soap is generally detrimental in eczema, especially in the acute form. It is a mistake to use strong ointments. Although the constitutional element in psoriasis is of more importance than in eczema, external treatment is comparatively of much greater use in this disease. Thyroid gland in the majority of cases has no effect. The external application of chrysarobin undoubtedly removes the efflorescence quicker than anything else. It should be used in the form of a solution, to be rubbed in only on the patches which are situated on the extensor surfaces. Forty grains of chrysarobin, 10 grains of salicylic acid, and one ounce of solution of gutta-percha (in chloroform), this forms a film which, when dry, does not stain the linen. For other parts of the body a strong tar or creolin ointment may be used, *e. g.*, one dram of creolin, 10 grains of ammoniated mercury, and an ounce of vaseline, also with the addition of from 10 to 20 grains of salicylic acid. For psoriasis of the scalp, the most efficacious treatment in my experience is an ointment containing a dram of ammoniated mercury and $3\frac{1}{2}$ drams each of soft soap and vaseline to be well rubbed in every night. **Impetigo** is a disease easily cured by ammoniated mercury ointment. The crusts should not be removed by poulticing. Warm oil or a weak, warm, antiseptic lotion ought to be sufficient. If pediculi are present, a thorough nightly washing with soft soap and hot water immediately before applying the ointment should be instituted. **Acne** is a common affection which can be cured with certainty and in comparatively short time by a judicious combination of internal and external remedies. The majority of cases are benefited by the tonic and aperient iron and magnesia mixture between meals, others by an alkaline bismuth mixture before food. In all cases an ointment which contains 30 grains of sulphur, 10 grains of ammoniated mercury, 10 grains of sulphide of mercury, and an ounce of vaseline should be used. The quantities in particular cases may be varied and oxid of zinc may be added if there be much inflammation. Before its application the patient should bathe the face with hot water and a 10% ichthyol soap well lathered on. But a still more important part of the treatment is the cautious application to each pimple of the tiniest drplet of pure carbolic acid, just liquefied with a little water. In **ringworm of the scalp** the following measures are efficacious: The scalp is to be shaved every fortnight, and calico skull caps to be worn day and night, an ointment consisting of one dram each of pure carbolic acid and salicylic acid to the ounce of vaseline is to be well rubbed in with a stiff brush night and morning over the patches, and the rest of the scalp slightly smeared over with the same ointment. Twice a week the scalp should be lathered with hot water and a soapy mixture containing 2 ounces of soft soap, 2 drams of glycerin of carbolic acid, and 2 drams of glycerin of boric acid, to be followed immediately by an application of the ointment. Once or twice aweek, if possible, immediately after the washing, a special pump which forces in by atmospheric pressure any parasiticide liquid which you may wish to use may be employed. [J.M.S.]

3.—During 1899 there were 1,316 cases of diphtheria in the wards of the Park Hospital; there were 275 cases of postdiphtheric paralysis and paresis, so that in about one case of diphtheria out of every 5 cases the patients suffered from paralysis or paresis. Out of 275 cases there were 174 cases that occurred between the ages of 3 and 8 years, equalling 63.2% of the total number. There were also 40 cases between the fifth and sixth year of age, equalling 14.5% of the fatal cases for all ages, which is in excess of any other period of life. Cardiac paralysis is clinically characterized by (1) heart-failure, (2) vomiting, (3) blueness of the skin and the mucous membrane, and (4) general coldness of the extremities in the final stage. Of 61 cases the average date upon which the symptoms appeared was the seventh day; the average duration of life after cardiac paralysis was first clinically noted was 4 days. There seems to be one particular kind of chart which occurs in the majority of cases of cardiac paralysis. For example, a patient, aged 6 years, was admitted on the fourth day of the disease with a temperature of nearly 101° F., which fell to 100° on the fifth day, then on the sixth day there was a drop to 97°, and though the temperature nearly rose to normal again for a

short time it kept near the 97° mark till the ninth day of the illness, when it was below 97° and death occurred. Large numbers of these cases show early and great swelling of the cervical glands, generally bilateral. There were 21 cases, or 7.6%, of diaphragmatic paresis and paralysis. Diaphragmatic paralysis rarely occurs without some other paralysis. Of 21 cases, 11 terminated fatally. The palate and the diaphragm; the palate, the internal rectus, the muscles of deglutition and the diaphragm; the palate, the ocular muscles, and the diaphragm; the larynx, the palate, the external rectus, and the diaphragm; the muscles of deglutition, the internal rectus, the ciliary muscle, and the diaphragm; the right external rectus, the flexors of the neck, and the diaphragm; the palate, the external rectus, and the diaphragm were some of the combinations of paralysis noted. There were 110 cases in which the palate alone was affected, which equalled 40%. [J.M.S.]

4.—Guiteras reports the results of treating 150 cases of gonorrhea with mercuriol, which he states is a combination of nucleic acid with mercury. The drug was first used in a strength of .25%, later increased to as high as 5%. The average strength best borne by patients was 2%. Complications resulted in only 2 cases; 1 of gonorrheal rheumatism, 1 of epididymitis and posterior urethritis resulted in only 1 case. Guiteras believes that the drug acts as a germicide, destroying the gonococcus, lessening the severity of the inflammation and tending to prevent complications. When gonococci are no longer found, if there be still some shreds in the urine it is better to change to a mild astringent solution. [M.B.T.]

5.—Bullmore does not believe that beriberi as it is seen in England is infectious or contagious; in fact, he does not consider that it is beriberi such as is met with in foreign countries. He puts forward the theory that the disease which reaches England is due to an alkaloidal poison fanned into flame by the disarranged digestion of sailors who are kept on improper diet, and that by properly dieting the vessels and supplying the captains with iron and digitalis tabloids the disease in all probability would be reduced to a considerable extent, if not stamped out. The necessity for the proper dieting of persons on board vessels is, of course, no original suggestion. Such precautions have answered admirably in the Japanese navy, and the author sees no reason why the British sailor should not have a similar fortunate experience. [J.M.S.]

6.—A woman, 46 years of age, had suffered for some years from chronic emphysema, chronic bronchitis, and heart disease. She had been in the habit of using drugs of various kinds to excess; from midnight to midnight 16 drams of paraldehyde was used and in the next 9 hours 3 drams more was taken. About 2 hours later 2 ounces more was taken. Unconsciousness, profuse perspiration, rather deep cyanosis, intermittent pulse, and shallow breathing, about normal in time, were noted and death occurred about 3 hours after the administration of the lethal dose. [J.M.S.]

7.—The case of a man who was suffering from vomiting and intense burning pain in the stomach and bowels is reported. When "in drink" 4 days before he had swallowed three-pennyworth of rat-killer. Immediately after swallowing it he complained of violent pain in the stomach and sickness. He was given salt and hot water, after which he was very sick and vomited freely and expressed himself relieved. On the next day he was a little better, although he felt far from well. When he was seen the patient's temperature was normal, he was quite conscious and coherent, and his pulse was 90. He complained of thirst, constant vomiting, and great pain in the stomach and abdomen. An examination of the vomit proved it to consist wholly of altered blood of a very dark color. His stools were also very dark and pitchy in character. He died a week after swallowing the poison. At autopsy the whole of the neck in its entire circumference, back and sides, bore the appearance of having been stained in a deep solution of Prussian blue, the color being most intense and brilliant; it was not mottled, but uniformly stained. The arms and legs showed an icteric tinge; their superficial veins looked as though they had been injected with a solution of Prussian-blue paint and were most beautifully mapped out. The stomach contained half a pint of liquid blood; it was deeply colored blue; it showed softening and ulcerations in patches and it was thickened in other parts. The whole of the intestines showed signs of an

irritant poison; they were deeply pigmented with the color, and the contents were dark and pitchy. The transverse colon was intensely inflamed and the fat of the great omentum showed bright extravasations of blood and was most striking in appearance. The heart, liver, and kidneys showed signs of commencing fatty degeneration. The lungs and the liver were deeply colored blue. The brain was rather anemic, soft, and almost diffident in parts. A diagnosis of phosphorus poisoning was made. [J.M.S.]

8.—A girl 15 years old had 94 warts on the right hand. She was revaccinated on June 1st. The operation was successful, but no effect was produced upon the warts until 7 weeks after, when, to use the description of the patient, the warts gradually "disappeared," leaving temporary white spots, and when the patient was seen, on August 30th, she had no trace of them. [J.M.S.]

9.—Two cases of resection of the lung for gangrene are reported. A man of 32 had been ill only 3 months with cough, expectoration, loss of flesh and an elevated temperature. There was dulness over the bases of both lungs posteriorly; the expectoration had a very offensive odor and separated into 3 typical layers. The seventh rib was resected, a portion of gangrenous lung removed and fetid pus evacuated. The patient rallied for a time, but died 4 days after the operation. In a second case a woman of 23 entered the hospital for pneumonia of the base of the right lung. Her illness continued without a crisis, and symptoms of gangrene of the lung developed. A portion of the eighth rib was excised in the post-scapular line. A large amount of pus and gangrenous sloughs were removed, iodoform emulsion was injected and an iodoform gauze plug inserted. Progress toward recovery was slow. Some time later tubercle-bacilli were found in the expectoration. The ultimate result is not given. [M.B.T.]

10.—A woman of 36, who had never had convulsions, was struck on the head by a policeman while intoxicated. After 2 weeks in prison she had an epileptiform fit. She gradually recovered and for 4 months was in fair health. Then the convulsions appeared again and the patient became progressively worse until she appeared moribund. The skull was trephined, but no evidence of tumor or bone lesion could be found. A drain was inserted and the wound closed. The convulsions continued 3 days, gradually diminishing in frequency and severity. Since this time there has been no return and the patient is now quite well. [M.B.T.]

Tuberculous Disease of the Middle Ear.—Milligan (*Transactions International Otolological Congress*, August, 1899) says the causes which predispose to this disease are: Hereditary tendency, unhealthy environment, unsuitable feeding, exposure to infection from tuberculous relatives, and the presence of tuberculous nasopharyngeal adenoids. He calls attention to the great difficulty of finding the tubercle-bacilli in the discharge from the ear; but better results are obtained by inoculating a guinea-pig with a small particle of diseased bone or other tissue removed from the pathologic area. The complications which may be feared are meningitis, tuberculous enteritis, and general marasmus. He separates the cases into nonoperative and operative. The first includes small children and others not sufficiently strong to stand an operation. When operation is done it must be performed very thoroughly as the effort to remove all diseased bone is well nigh impossible. The author's conclusions are as follows: 1. Primary tuberculous disease in and around the middle ear is of fairly frequent occurrence, and that it most usually attacks the children of the poor, especially the poor of our large cities. 2. That a generalized tuberculous infection may arise from a primary focus within or around the middle ear. 3. That the prognosis of such cases is not very favorable, at least 40 to 50% of the cases succumbing even after operative treatment has been undertaken. 4. That in many of the cases operative treatment is contraindicated owing to the extent of existing diseases and the asthenic condition of the patient. 5. That when operative interference is possible the main object should be to scrape away all the foci of disease and to provide efficient drainage. 6. That the best and most reliable means of establishing the tuberculous nature of the disease is by means of properly conducted inoculation experiments. [A.B.C.]

Original Articles.

GENERAL SUMMARY OF THE CASES OF TYPHOID
FEVER TREATED IN THE JOHNS HOPKINS HOS-
PITAL FOR TEN YEARS.*

By WILLIAM OSLER, M.D.,

Professor of Medicine, Johns Hopkins University.

DURING the ten years to May 15, 1899, 829 cases of typhoid fever were treated in the medical wards of the Johns Hopkins Hospital. The patients have been under my personal care, or, in my absence, under the care of Dr. Laffleur (to October, 1891), Dr. Thayer (October, 1891, to October, 1898), and Dr. Fletcher, my present first assistant. Not a little of the value of these records is due to a uniformity in the methods of observation, of record and of treatment, which cannot be reached in large general hospitals with four or five different medical services.

The following statistical details relate to age, sex, race, etc.:

SEX—631 cases were males and 198 were females.

RACE—729 cases were white and 100 were colored.

NATIONALITY.—Of the 729 whites, the nationality was as follows: Americans, 348; Germans, 200; Irish, 39; Bohemians, 30; English, 28; Poles, 21; Russians, 19; Scandinavians, 15; Lithuanians, 5; Scotch, 4; Italians, 3; Finns, 2; French, 2; Danes, 2; Swiss, 1; Austrian, 1; Welsh, 1; Dutch, 1; Hungarian, 1; West Indian, 1; Syrian 1; not given, 4.

AGE.—Five to fifteen, 99; fifteen to twenty, 159; twenty to thirty, 393; thirty to forty, 125; forty to fifty, 40; fifty to sixty, 6; sixty to seventy, 6; not given, 1.

SEASON.—The admissions in each month were as follows: January, 37; February, 15; March, 13; April, 27; May, 16; June, 24; July, 91; August, 169; September, 169; October, 122; November, 96; December, 50.

LOCALITY.—From the city of Baltimore, 590 cases; from Baltimore county, 139; from Maryland, outside Baltimore county, 29; from outside Maryland, 60; from steamers, 7; not given, 4.

MORTALITY.—In the 829 cases, there were 63 deaths, a rate of 7.5%. This represents the total death-rate of all the cases admitted to the hospital in which a positive diagnosis of typhoid fever was made. It therefore includes the group of cases met with in all general hospitals, to which patients are frequently admitted in a moribund condition, or so ill that death occurs within three or four days.

TREATMENT.—In the two previous reports I have dealt fully with the method of treatment, and to it I have nothing to add. It consists in:

1. A careful and thorough system of *nursing*, to which, as much as to any other single feature, I attribute the comparatively low rate of mortality for a general hospital. Our proportion of nurses to patients is above the average. We have been fortunate in having as head nurses in the wards unusually able and devoted women, who have made the nursing of the typhoid fever patients their particular study. To Miss Hampton, to her successor, Miss Nutting, to the head nurses, and to their assistants, I am personally under a lasting obligation.

2. *Diet*. Milk, diluted with limewater, and egg albumen form the standard diet of the febrile stage. We rarely order artificial foods. The milk has not often to be peptonized, and we have had on the whole singularly few gastric complications, and comparatively few instances of serious bowel trouble. The patients are given in addition an abundance of cold water.

3. *Hydrotherapy*, either the full tub at 70°, or, if occasion requires, ice-cold sponges. Full details of this are given in *Studies* No. II.

4. *Drugs*. As a rule no medicines are given. If the pulse becomes rapid and feeble we give alcohol in the

form of good whisky, and strychnia, if necessary, in full doses. We use no antipyretics, and no intestinal disinfectants. Special complications, of course, require and receive appropriate treatment.

SYMPTOMS, COMPLICATIONS, ETC.

SYMPTOMS OF ONSET.—No features are more uncertain or indefinite in hospital histories than those relating to the onset of the disease. The patient is generally brought in by friends or relatives, who know very little about the case; there may be no statement from the doctor, and very often the patient himself is not in a condition to give an intelligent account of how his trouble began. The following is an analysis of the symptoms of onset as presented by the 829 cases: Headache, 595 cases; loss of appetite, anorexia, 414 cases; diarrhea, without medicine, 322 cases; with medicine, 21 cases; cough, 233 cases; abdominal pain, 27 cases; chilly sensations, 213 cases; vomiting, 209 cases; chills, 200 cases, of which 107 had a single chill, and 93 cases had two or more chills; epistaxis, 182 cases; malaise, 169 cases; constipation, 152 cases; general pains, 128 cases; nausea, 114 cases; sweats, 114 cases; backache, 99 cases; vertigo, 45 cases; delirium, 31 cases; stiffness of the neck, 30 cases; sore throat, 20 cases; pain in the right iliac fossa, 6 cases; 8 complained of deafness at onset; 1 of hiccough; in 4, one of the early symptoms was bleeding from the bowels.

THE RASH.—Rose-spots were present in 656 cases, 80% of the 829 cases.

THE FEVER.—In 592 of the 829 cases the rectal temperature registered 101° and over. Between 104° and 105° there were 329 cases; between 105° and 106° there were 240 cases; between 106° and 107° there were 27 cases; at 107° and over there were 6 cases.

THE PULSE.—There were 345 of the 829 cases with a pulse of 120 and over. Between 120 and 130 there were 168 cases; between 130 and 140 there were 72 cases; between 140 and 150 there were 59 cases; between 150 and 160 there were 13 cases; above 160 there were 33 cases.

DIARRHEA.—We have already stated that there was diarrhea at onset in 322 cases before the patient entered the hospital. During the stay in hospital, 163 of the 829 cases, *i. e.* 19%, had diarrhea at some time or other in the course of the disease, and 290 cases, 34%, presented constipation. This remarkably small percentage of cases with diarrhea may in part, at least, be attributed to our practice of not disturbing the bowels with laxatives or antiseptics.

SPLEEN.—As I stated in *Studies* No. II, we place much more reliance upon palpation than percussion in estimating an increase in the size of this organ. The left hand is placed on the side, the fingers well behind on the ninth, tenth and eleventh ribs, the palm of the hand over the splenic region itself. The patient is then asked to draw a deep breath. As he does, the fingers of the hand press forward, the palm of the hand laterally, and the diaphragm during inspiration presses downward and forward, so that by these movements, if the spleen is at all enlarged, the edge appears at the costal margin, where it can be readily felt by the fingers of the right hand, which are placed just below the costal margin between the parasternal line and the tip of the tenth rib. It is well to make the palpation just as the abdominal walls relax, following their recession quickly. In many cases the edge of the spleen can be seen tilting over the fingers of the right hand. It is well to remember that in children the edge of the spleen may sometimes be felt best as low as the tip of the tenth rib. In 591 of the 829 cases the spleen was palpable, 71%.

CHILLS.—In *Studies* No. II there is an article on the occurrence of chills in typhoid fever, considered under the headings of (a) at the onset of the disease; (b) at the onset of the relapse; (c) as a result of treatment; (d) with the onset of complications; (e) septic chills during convalescence in protracted cases; and (f) chills due to concurrent malaria. In the third series there were nine additional cases of chills:

RELAPSE.—We recognize two varieties: First, a genuine relapse, in which there is a reinfection after a distinct and definite period of apyrexia; secondly, the intercurrent relapse, in which, after the temperature has fallen nearly to normal, or after the morning temperature has been at 99° or 99.5° for three or four days, and there has been a decided

* From the forthcoming *Studies on Typhoid Fever*, III. *Johns Hopkins Hospital Reports*, vol. viii.

hull in the symptoms, the fever again rises, and the patient goes through all the features of another attack. The conditions under which relapse occurs are not, I think, as a rule, within the control of the physician. The sources of the reinfection are doubtful. The typhoid bacilli linger in the adenoid tissues of the mucous membrane for a long time, and Dr. Mark Richardson has shown that they may be found in the stools even after a considerable period of apyrexia. We know, too, that they remain for a long time in the mesenteric glands and in the spleen. The interesting observations by Chiari, amply confirmed by others, that typhoid bacilli may remain in the gallbladder for an indefinite period, suggest that this may sometimes be the source of reinfection. Errors in diet may be associated with gastric disturbance, and the passage of a large number of bacilli from the bile-ducts into the intestines.

We are still really without full knowledge of the causes of relapse, but the frequent occurrence is a positive indication that immunity in typhoid fever is slowly acquired, and not reached at the period of apyrexia.

Incidence of Relapse.—In the 829 cases there were 86¹ relapses, a percentage of a little more than 10. In this we have included the intercurrent relapse.

The periods of complete apyrexia in the third series were as follows: 3, 9, 7, 5, 3, 5, 10, 4, 7, 8, 9, 4, 4, 23, 8, 1, 6, 19, 8, 4, 16, 15, 11, 10, 7, 4, 1, 36, 4, 7, 8, 13, 3, 3, 2, 8, 11, 5, 8, 8, 11 days.

POSTTYPHOID VARIATIONS OF TEMPERATURE.

The special care and the frequency with which the temperature is taken in our typhoid-fever patients (every two or every four hours), has brought out some interesting points. These may be considered under the following heads:

I. **THE SUBFEBRILE STATE IN CONVALESCENCE.**—In children, in nervous patients and in very protracted cases the general symptoms may improve, the tongue become clean, the appetite return and everything may look favorable, but the thermometer may show a daily rise to 100° or 100.5°, continuing for ten days or even three weeks, and may be a source of no little anxiety. If the spleen is not palpable, if the tongue is clean, the appetite and strength returning, and the urine free from typhoid bacilli, the best plan is to stop taking the temperature, let the patient sit up, and begin to give solid food. In some persons, particularly in children and in nervous subjects, the normal diurnal range of temperature may be between 97.5° and 100°. In a number of instances of this kind I have never seen any ill effects from the plan suggested.

II. **HYPOTHERMIA.**—Our records have taught us that low temperatures are very common in two diseases—malaria and typhoid fever. In the latter we see it—

(a) *As an effect of the tub, particularly in the third week.* Following the bath for an hour or more the rectal temperature may not be more than 97°. This is an every day occurrence in the wards.

(b) *Spontaneously in the third and fourth weeks,* at the period of marked remissions, the temperature may sink as low as 97°. The lowest temperature I remember to have seen during the spontaneous remissions of the disease was in a case which I saw with Dr. Delano Ames. On the twelfth day of the disease the patient had a very severe hemorrhage, which had reduced the temperature to 95°. He subsequently did well, but the attack was protracted, and in the fifth and sixth weeks there were extraordinary variations in temperature. Thus, on the thirty-sixth day the temperature fell from 102.2° at 11 A. M. to 94.5° at 1 A. M. on the following morning. It then rose 8° by 10 A. M. on the thirty-eighth day, but dropped again to 94.7° by 6 A. M. on the following day. He made a good recovery.

(c) *Following hemorrhage.* Here the temperature drop may be 8° or even 10°. It rarely falls below 98°, though I have one record showing 95°. The temperature may remain low for 24 or 36 hours.

(d) *Persistent hypothermia during convalescence.* For a week or 10 days, or longer, more particularly after protracted cases with great emaciation, the temperature may be 97° or 96.5°, and for days the maximum may not reach 98°. This is quite a common event, which is illustrated by some scores of our charts. It is of no special significance.

¹ This number includes also Cases 7147, 7218, 8148, and 10,657, omitted inadvertently in *Studies* N. 11.

III. **RECURRING PAROXYSMS OF CHILLS AND FEVER.**—In *Studies* No. II I have dealt quite fully with the subject of chills in typhoid fever, and have given a number of illustrative cases. It is not sufficiently recognized that in the protracted convalescence paroxysms of fever with chills may recur at intervals for several weeks, and this in the absence of any signs whatever of localized trouble.

COMPLICATIONS AND SEQUELÆ.

HEMORRHAGE FROM THE BOWELS.—There were 50 cases in the 829 in which blood appeared in the stools, in large or in small quantities, a percentage of 6. Of these 5 cases died, a percentage of 10.

PERFORATION.—The question of perforation in typhoid fever is discussed with great fulness in the papers by Dr. Finney and Dr. Cushing in this number of the report. In the series of 829 cases there were 23 instances of perforation, a percentage of 2.7. Of these 3 recovered after operation.

Hæmatemesis.—F. R. H., male, aged 22 (Hosp. No. 14,933), admitted January 9, 1896. Vomiting of blood on twentieth and twenty-first days.

PHLEBITIS.—There were 16 cases of phlebitis of the veins of the leg in the 829 cases, a percentage of 1.9. Of these only 2 occurred on the right side, in both in the popliteal vein. Of the 16 cases of phlebitis 7 occurred in the femoral vein, 4 in the popliteal, 4 in the long saphenous, and 1 in a superficial varicose vein of the left thigh.

PNEUMONIA.—We may divide pneumonia in typhoid fever into two groups, according to its appearance with the onset, during the course, or toward the termination of the disease.

Pneumonia at Onset.—The interesting feature of this form, the so-called pneumotypoid of the French, is that the cases may present all the characteristics of ordinary croupous pneumonia, no other diagnosis may be reached, and it may not be corrected until autopsy. In *Studies* No. I, page 29, the history is given of a remarkable case of this character, in which clinically we had no suspicion that there was any other disease than pneumonia, but the autopsy showed characteristic typhoid fever. Two other cases occurred in this series.

Pneumonia During the Course.—This forms a frequent and very serious complication of the disease, of which there were 15 cases in the 829.

URINE.—*Albumin* was present in 616 of the 829 cases, 74%.

Tube-casts were present in 391 of the 829 cases, 47%.

Diazo reaction was present in 543 out of 796 of the cases, 68%. The test was not made in the first 33 cases treated in hospital.

ACUTE NEPHRITIS.—Although albuminuria is so common in typhoid fever, accompanied also by tube-casts, it rarely is a serious condition, and indicates only the mildest possible grade of disturbance in the function of the kidney. In a more aggravated condition where the albumin is in larger amount, hyaline and granular casts and red blood-corpuscles are abundant, we have to consider it an acute nephritis. There are two interesting features of the typhoid nephritis. There is rarely dropsy, and it clears up as a rule completely. We have had no instance in the series, nor do I remember in my experience a single case in which a chronic nephritis followed the acute attack.

ORCHITIS.—One of the rarest complications of typhoid fever is orchitis, of which only 2 cases occurred in the series of 829 cases. Eshner² has collected 42 cases, a large majority of which, 29 cases, occurred during convalescence.

HERPES.—The statement is usually made that herpes is very rare in typhoid fever, but it was noted in 29 of the 829 cases, and probably occurred in a great many more. So frequent is herpes in malarial fever that its presence is often an important diagnostic suggestion.

For additional complications the reader is referred to the forthcoming fasciculus.

Sun-Baths.—An establishment for the giving of sun-baths has recently been opened in Strelau, a suburb of Berlin, and is extensively patronized. Many Berlin physicians prescribe these baths for nervous complaints.

² PHILADELPHIA MEDICAL JOURNAL, 1888, 1.

A REVIEW OF THE HISTORY OF CARDIAC PATHOLOGY, WITH ESPECIAL REFERENCE TO MODERN CONCEPTIONS OF MYOCARDIAL DISEASE.*

By ALFRED STENGEL, M.D.,

Professor of Clinical Medicine, University of Pennsylvania.

ONE is tempted at the end or beginning of a century to indulge oneself in reflections on the progress of knowledge to become retrospective, to estimate advances, to review with a feeling of superiority and pride of achievement the ignorance of the past, to dwell with fond fancy on the enlightened intelligence of the present, and finally, perhaps, to animadvert upon the problems of the future. Whether any real good is ever accomplished by such mental attitudes, and whether a consideration of the past and present ever leads to any significant advances in the future, is an open question, but at all events you will admit that it is a commendable feeling that prompts one to indulge in this diversion.

I have selected as a subject worthy of your attention the development of knowledge regarding Cardiac Pathology, because, as we shall see, this lies at the very root of all medical progress. The revival of medicine had its origin in the epoch-making discovery of the circulation, and our science reached its highest development with the acquirement of accurate knowledge regarding the vascular system.

Modern medicine, then, may be considered as having an age of about three centuries. The first or seventeenth century was taken up with the establishment of general principles and methods which have served as the foundation of subsequent advancements; the second or eighteenth century was given to the development of these principles and to the accumulation of many details of unclassified knowledge; while the third or nineteenth century established the science of medicine upon a foundation which would justify its classification among the exact sciences.

The diffusion of general knowledge through the perfection of the art of printing, the multiplication of universities and institutions of learning, and above all else, the greater freedom of the people, serve to make the opening of the seventeenth century the epoch of the revival of learning, and brought to an end forever the dark ages of fanaticism, ignorance, and oppression.

It is difficult to picture to the mind the condition of medicine at that time, but it is sufficient to point out that the medicine of the sixteenth century, like the medicine of the second and third centuries, was absolutely dominated by the teachings of Hippocrates and Galen, though supplemented and perhaps in some measure improved by the mystical, delusional theories and methods of Paracelsus. A better idea may be obtained of the character of the medicine of that period by a review of the teaching as practised in the University of Heidelberg.

The first professor, whose teaching was confined to therapeutics, followed certain books of Galen, namely, "de methodo medendi," "de ratione victus acutorum," "de compositione medicamentorum sec. locos," and "de ratione curandi per sanguinis missionem;" the books of Trallianus; the third book of Aeginetus; and the works of Rhazis. The exact distribution of his lectures was: (1) A short description of the names and

definition of disease as given by the Greeks and Arabs, Latins, and to some extent by the Germans; (2) the nature of the disease, because without a knowledge of this a correct cure would be impossible; (3) the signs and indications of disease of the parts affected; (4) the prognosis according to individual experience and with reference to the prognostic aphorisms of Hippocrates; (5) the cure of disease, giving the general indications and the special indications, with particular reference to the practice of the Arabians—Avicenna, Rhazis, Serapion, etc.; and (6) the prevention of disease. The second professor taught pathology. In the first fourteen months he discoursed on the sixth book of Galen concerning the different causes of disease and of symptoms, and in the next ten months on the causes of fevers, and in the twenty-four subsequent months on local diseases, etc., etc. The third professor, who taught physiology, discussed the elements, temperaments, liquids and powers of the body, with anatomy and medical botany, and performed anatomies on human subjects as well as on animals. The fourth professor taught surgery, and used as his guides Hippocrates, Galen, and Tagault, and to some extent in the course of time he relieved the anatomical professor.

The first professorship of anatomy was established in Strasburg in 1652, and at The Hague in 1668. The dates of establishment of anatomical theatres were: Dresden 1617, Strasburg 1671, Bremen 1685, Edinburgh 1697.

Practical bedside teaching was first undertaken privately by Otto Heurnius and Ewald Schrevelius in Leyden in 1636, and by Albert Kyper in the same place in 1648, but was discontinued on account of the lack of interest of the students for this new method of teaching. It was first successfully carried out by de la Boc Sylvius in 1658 at Leyden.

The scientific tendency of medicine was to some extent stimulated by the notable philosophical contributions of Francis Bacon (1561-1626), though the *Novum Organum* of the latter did not actually exercise a great influence upon the scientific world until the present century. Probably the *Principia* of Rene Descartes, published in 1664, had a more immediate effect upon the scientific world. The philosophical teaching of Locke, and the scientific writings of Glisson and Isaac Newton during the same period, and the mathematical influence of John Kepler and of Galileo, were among the other influences that were potent in forming new methods of teaching and of study.

It is remarkable that during this period of awakening into intellectual activity, the practical branches, or the teaching of practice itself, was still clouded with all the mysticism of the previous and preceding centuries. The teaching of the great Belgian physician, Jno. Baptist van Helmont, of Brussels (1578-1644), was paramount. Helmont first studied philosophy, then theology and magic under the Jesuits, then jurisprudence, natural history, and finally medicine. The practical application of medicine and even of surgery was distasteful to him, and he naturally fell into the consideration of mystics. Like his great master, Paracelsus, his teaching lacked all consecutiveness and was clouded with impenetrable obscurity.

Not until the end of this century was the practice of medicine wrested from the guidance of the mystics by the practical sense, the wide experience and attainments of Boerhaave, of Leyden, while in England a still more powerful influence was exercised by the writings and

* An address in Medicine, delivered before the Wisconsin State Medical Society, June 21, 1900.

the teaching of Thomas Sydenham (1624-1689), the most notable figure in the history of medicine in England, and one who has been deservedly called the English Hippocrates. The influence of Bacon is strongly marked in the writing and in the methods of Sydenham. The early life of Sydenham is more or less obscure. His first visit to Oxford in 1642, his departure the next year to join the Parliamentary army, in which he reached the rank of Captain, his reentry into Oxford in 1645, and his graduation as a Bachelor of Medicine in 1648, are facts that have been established. He later visited Montpellier and there received the bent for the Hippocratic method which is apparent even in his latest writings.

It will be observed that ancient medicine consisted essentially in a knowledge of certain anatomical facts and in an abundance of theories and crude beliefs, whose publication and subsequent perpetuation by men of undoubted great ability almost passes belief. Outside of anatomy there was only the vaguest speculation regarding the physiology of life and the nature of disease. It is, therefore, not unnatural that in anatomy the revival of medical learning found its first expression. Practically nothing had been added since Galen, and medical progress was absolutely at a standstill throughout Europe, though a few progressive spirits remained in Arabia, Africa, and Spain. The revival of anatomical knowledge, or rather the birth of modern anatomy, was found at the University of Bologna, which reached its highest state in the thirteenth and fourteenth centuries, and which was the mother school from which Padua and Naples sprang. As in many other movements that have had powerful consequences, it was the intelligence, energy, and genius of one man who gave to this movement so powerful an impulse that its progress was subsequently irresistible. The credit for this achievement is due to Mondino, Professor of Anatomy, at Bologna, who first gave anatomical demonstrations in 1315 and attracted a large number of earnest pupils, who carried to every quarter of the world the spirit and the method of their master. It will be remembered that among the ancient Greeks, the practice of dissection had been carried on to some extent on human subjects, while the prosecution of anatomical research in the lower animals had been more extensive. Subsequent to this era, however, the religious beliefs of the Arabians, who formed the only progressive school of medicine, and the practical slumber of all intellectual effort in Europe, had caused a cessation of advancement, and the revival of anatomical investigations at Bologna under the guidance of Mondino was, therefore, the starting point of a renewed activity. Isolated facts were gathered through the labors of various anatomists of lesser prominence during the fourteenth and fifteenth centuries, but it remained for the sixteenth century to bring forth Vesalius, the real father of modern anatomy. Andreas Vesalius was born in Brussels in 1515, but studied in Venice, and was engaged in teaching at the latter place in 1536. Subsequently he was called to Padua, where he completed his successful career. He was the first among the anatomists to approach the subject from an entirely new standpoint, not accepting the dogmas of Galen, or attempting merely to fulfil or complete the teaching of the latter, but founding an entirely new anatomy from personal and original observations. It is interesting to note, however, that even Vesalius could not entirely escape the influence of Galen, and caused two muscles to be drawn in his

plates, though he could not find them in his dissections. Galen had seen them in dissecting lower animals.

It is in the study of the circulation of the blood that we find the real springs of origin of modern medicine in its strictest sense.

The ancient belief was that the arteries were channels for the conveyance of air or spiritus. Galen in the second century first showed that the arteries contain blood and not air, as had been taught since Praxagoras and Erasistratus. It is certain that the ancients knew something about the movements of the blood in the body as has frequently been pointed out. Homer refers to the flow of blood, Plato speaks of it, and the experience of battlefields was frequently cited, but there is nothing to show that any one had a distinct conception of the systematic movement of this flow through definite channels and in a regularly continued direction. In 1559, Caesalpinus first used the term "circulatio," but this probably was applied, as one critic remarks, in the same spirit as a French policeman says "circulez."

Sylvius recognized the valves of the veins in the sixteenth century, Fabricius ab Aquapendente described the heart-valves, and Vesalius recognized that the inter-ventricular septum is complete, though he still accepted Galen's "invisible pores," by which intercommunication might take place between the ventricles.

Servetus (1531) could not believe in this form of communication, and on this account and because of the large size of the pulmonary veins, concluded that there must be some communication between the pulmonary arteries and veins in the lungs. He was thus the first to have any suspicion of the actual circulation of the blood. Realdo Columbus (1559), had somewhat similar views as Servetus. The complete demonstration of the circulation, however, was left for Harvey, the most notable figure in medicine in the seventeenth century. William Harvey was born at Folkestone, near Dover, April 1, 1578. He received his early education at Canterbury, and then entered Cambridge. At the age of twenty-one, he visited Padua, and studied under Fabricius, Casserrius, Minadous, and Servetus during two years. He received the professorship of Anatomy in 1615, and was physician to James I, in 1623. His first public discussion of the circulation of the blood took place in 1619, but his book entitled "*Exercitatio anatomica de motu cordis et sanguinis in animalibus*," etc., appeared in 1628. He became physician to Charles I, in 1632, and during his attendance upon the King, prosecuted important studies in the comparative anatomy of reproduction. The publication of Harvey's views on the circulation divided the medical world into two opposed schools, those who supported his views and those who opposed them, and in this connection it is necessary to observe that there was still a point of incompleteness in the circulation according to Harvey's notions. He had not been able to demonstrate the capillaries, and therefore assumed "porosity of the flesh" or tissues as the necessary connecting link. The capillaries were finally demonstrated after Harvey's time by Malpighius.

The influence of Harvey's discovery and demonstration was soon manifested in the establishment of accurate knowledge regarding certain fundamental principles of physiology and in a reliable view of anatomy. One of his contemporaries, Francis Glisson, of London, laid perhaps the first foundation of the modern conceptions of physiology in his principles of the irritability of tissues, an expression which he used to illustrate not

merely a contractility or contractibility, but a responsiveness to impressions or irritations of a general sort. His observations were carried much further, and were perfected in the beginning of the eighteenth century by Haller, who may be regarded as the founder of modern physiology. Contemporaneously with Glisson, Morgagni, of Padua, established pathological anatomy, having gathered together in his monumental work "On the Seats and Causes of Disease," all the reliable facts known to that time, and having added innumerable personal observations of the greatest exactness and merit. To this day, the volumes of Morgagni may be consulted with profit, and frequently surprise even informed pathologists by the accuracy of his observations.

As it was the discovery of the circulation that gave the first powerful impetus to modern medicine, it is not inappropriate that I devote my attention now to the consideration of the evolution of our present conceptions of cardiac pathology.

Some attention was given to the anatomy of the heart in the works of Hippocrates, though it must be considered doubtful whether these observations originated with Hippocrates and not with some of his followers. Galen's knowledge was considerably more extensive. Hippocrates and Celsus taught that the heart could not be diseased, but Galen observed pathologic conditions in the hearts of animals and discussed the possibility of their occurring in man. Galen, however, did not recognize the muscular structure of the heart, an anatomic fact which was first established by Steno in the seventeenth century. The valves of the heart had been recognized somewhat earlier by Fabricius ab Aquapendente (1574) and the imperforate character of the ventricular septum a little later by Servetus. After Harvey's demonstrations, scattered observations on the anatomy of the heart were made by Bonet, Valsalva, Vieussens, Lancisi, and Albertini; but the most important of all by Senac in France, and Morgagni in Italy. The former developed knowledge regarding cardiac disease in a clinical as well as a pathological way, but Morgagni was the first great exponent of the pathology of the heart as he was the founder of all pathology. Little, however, was known regarding the relation of the heart diseases to clinical symptoms, though Lancisi had indicated a connection of cardiac disease and asthma, though Vieussens had described quite accurately the character of the pulse in aortic regurgitation, and though Albertini recognized the alteration in the apex beat occasioned by hypertrophy and pericardial disease. In a pathologic direction, Vieussens observed the congestive effects of mitral disease, Morgagni appreciated the effects of pericardial effusion and adhesion, of enlargement of the heart and of aortic aneurysm. Harvey had long before reported a case of rupture of the heart, isolated cases of myocarditis were described by Beniveni, Bonet, Morgagni, and Senac. Fatty degeneration, or more probably fatty infiltration of the skeletal muscles had been seen by Haller, but was more carefully observed by Vieq d'Azyr, the physician of Marie Antoinette. Aneurysm of the heart had been described by Massa in 1534, and aneurysm of the aorta had been recognized during the life of a patient by Vesalius. Peripheral aneurysms had been mentioned by Galen, Paulus, Aribasius, Atius, Actuarius, and Avicenna, but none of these had recognized aneurysm of the heart or the great vessels.

All of these were, however, merely scattered obser-

vations, buried in the works of the masters and of no consequence so far as the general medical mind was concerned. Throughout the eighteenth century, clinical observations of sudden deaths and of stagnations of the circulation, of asthma with cardiac disease, and of swellings or dropsies, replaced ignorance with a confusion out of which the genius of Corvisart finally rescued medical science. Jean Nicholas Corvisart des Marets was born at Veuziers in Champagne on February 15, 1755. He became distinguished as the physician of Napoleon I, who said of him that he was the most brilliant and the most incorruptible of his followers. He had the merit of recognizing the great value of Auenbrugger's neglected method of percussion, which the now celebrated but then unknown Viennese clinician had published in 1761. Auenbrugger had applied his method in cardiac disease, and had indicated its applicability in the recognition of pericardial effusion and enlargement of the heart; but the systematic application of percussion to diagnosis was effected by Corvisart. Apart from his clinical achievements, he classified the observations of his predecessors and in particular called attention to the nature and causes as well as the symptoms of active and passive aneurysm of the heart, or as we would say today—hypertrophy and dilation; he described more accurately than his predecessors the various forms of pericarditis, recognized the relation of apoplexy to cardiac diseases, and discussed the pathology of acute vegetative endocarditis and of contractions and distortions of the valves following this condition. He appreciated the importance of congenital lesions of the heart in the production of cyanosis and the nature of thrills due to stenosis. One method of exploration of cardiac disease was, however, unknown to Corvisart, though his contemporary, Laennec, immortalized himself by its discovery before Corvisart's death. One day in crossing the garden of the Tuileries, Laennec was interested by a group of children who amused themselves by placing one end of a short piece of wood to their ears and scratching the other end, thus causing a peculiar transmission of sound. This led to his discovery of the art of auscultation, which he published in his work entitled "Medical Auscultation" in 1819, just two hundred years after Harvey's first public demonstration. With the introduction of two such valuable methods as Auenbrugger's percussion and the auscultation of Laennec, means were furnished for the rapid increase of knowledge regarding the diseases of the heart. Up to the time of Corvisart's death the valves of the heart had received very little attention, but soon after, through the clinical and pathologic studies of Bretin and his more illustrious pupil Bouillaud, the importance of the valves was appreciated, and cardiac diagnosis was further enriched by the works of Hope, Testa, Burns, and Kreysig.

In the way of a rapid review of the subject to this date (the early years of the nineteenth century) let me recall that the father of medicine, Hippocrates, and his pupils knew practically nothing of the functions or structure of the heart and that they denied the possibility of diseases of its structures; that Galen first indicated the probability of diseases of this organ, though he did not recognize the muscular structure and therefore had no possible conception of the real nature of cardiac disease; that through fifteen centuries little or nothing was added to Galen's ignorance; and that the first light to break in upon this obscurity was cast by Harvey's brilliant demonstration of the circulation

of the blood. After Harvey, little by little anatomic, physiologic, and finally pathologic facts of importance were added, and were eventually classified and amplified by Morgagni. Diseases of the heart were, however, little more than interesting curiosities, whose clinical relations were guessed at but never understood till the eminent French physician Corvisart brought a wealth of learning and abundance of experience to the task of clarifying the obscurity and classifying a mass of ill-digested knowledge. With Corvisart, however, the conception of cardiac disease stopped short of recognizing other than in a vague way the causes which operate to produce the diseases which he was able to describe so beautifully. The merit of making an important addition, the recognition of the potent part played by valvular disease, is Bouillaud's, and to him is due the credit of establishing notions regarding the pathology of the heart that have endured to the present day, and which it is one of my purposes in some measure to combat.

The role of the heart-muscle, and it is this to which I desire to call especial attention, was, of course, appreciated to some extent in the classification of Corvisart and was discussed by Bouillaud, though neither of these authors had a true conception of the prime importance of this part of the cardiac mechanism, Corvisart, because of his limited knowledge of the significance of hypertrophy and dilation, and Bouillaud, because of his too earnest advocacy of the importance of the heart-valve. For the former, cardiac disease was an obscure condition without definitely ascertained causes, for the latter it represented only mechanical problems immediately connected with valvular disease. It would not, however, give a just notion of the state of knowledge at the beginning of the century, if no further allusion was made to knowledge regarding the existence of muscular disease of the heart. I have before remarked that several of the older anatomists described cases of myocarditis, and in a study of the literature the frequent occurrence of the term "carditis" at first sight gives the impression that inflammation or disease of the substance of the heart was well recognized. Such a view, however, would exaggerate the state of knowledge, even at the time of Corvisart, for it was not until some years after the appearance of his work that Laennec pointed out the fact suspected by Corvisart, that in many, if not the most instances, this condition termed "carditis" was simply purulent pericarditis with secondary affection of the superficial layers of the muscle. Fatty disease of the muscles had been recognized as I have said by Haller and Vicq d'Azyr, but not of the heart. Observations of similar change in the heart-muscle were, however, recorded by later anatomists, and Corvisart, though he himself never observed such, refers to instances described by Kerkringius and Bonet. In each of these instances the condition seems from the descriptions to have been that of fatty infiltration or overgrowth. Another case is referred to by Morgagni in his third letter, article 20.

Fibroid change had now and then been alluded to by older writers, though the nature of the condition was not understood. Here again I must return to Corvisart, who states: "The *induration*, of which I am here speaking, must not be confounded with a thickening of the parietes of the heart sometimes acquire in aneurysm of the first species. Here, the fleshy fibers, though thicker and firmer, retain all their contractility, while the morbid state under examination is distinguished by

the more or less partial loss of muscular contractility; besides, this state is very seldom attended with any dilation.

"I have frequently noticed the *induration* of the muscular tissue of the heart; but in these numerous cases the induration has attained to different degrees. The following case which was inserted in the *Journal de Medecine* (Ventôse, an 9) will give the most remarkable example of this affection that I have seen."

The case referred to was that of a woman, aged 55, who succumbed to an evident cardiac disease with some anginoid manifestations. The heart-muscles were of unusual firmness, especially the wall of the left ventricle, which was twice its normal thickness and "actually formed a fleshy, very elastic sounding-box when struck, as if we had struck upon a sort of cornet." The author points to the peculiar weakness of the pulse in this case in contrast with the great size of the heart, and very properly calls attention to the difference between this induration and true hypertrophy.

In another place he suggests the occasional occurrence of insidious carditis without symptoms, basing this opinion upon his discovery of lesions suggesting a healed carditis; but it is most likely that the cases he refers to were instances of chronic pericardial adhesions.

Accurate knowledge regarding myocardial disease, however, dates from the middle of this century and must be credited among others to the observations of Hasse, Rokitsansky, Bochdalek, Dittrich, and Virchow. In the same group must be placed the name of Gairdner, who long ago suggested the relation of arterial disease (coronary sclerosis) to myocardial degenerations, and that of Weigert, who first established this relationship in a convincing manner. Finally Bamberger in 1857, in discussing the consequences of fatty disease of the heart-muscle, introduced the term "insufficiency of the heart," and this gave the first impetus to a new conception of cardiac pathology, that which seeks in the mutual relationship of cardiac power and circulatory obstacles the explanation of clinical conditions. This impetus had its consequences in a careful clinical study of the heart under various conditions of strain and the writings of Allbutt, Myers, Seitz, and DaCosta established a clinical picture of cardiac disease without valvular lesions. The absence in some cases of pathologic lesions in the muscle of the heart was emphasized by Niemeyer in his often-quoted statement "that it is not always possible by means of the microscope to recognize all the alterations of the muscular fibrillae that diminish the functional power of the heart."

Subsequently Bollinger and his pupils in Munich described a peculiar form of enlargement of the heart which was very frequently met with among beer drinkers. This condition consisted in a uniform enlargement of the organ occasioned by muscular hypertrophy without valve disease, arterial disease, or interstitial nephritis. The term idiopathic enlargement or hypertrophy had previously been introduced to indicate forms of hypertrophy not occasioned by valve disease. Undoubtedly many instances of supposed idiopathic hypertrophy are in reality cases of fibroid degeneration or interstitial myocarditis, with which hypertrophy of the muscle-fibers is constantly associated. In proof of this view, I may cite the interesting example of enormous enlargement of the heart described by Quain, at first as a simple hypertrophy, but many years subsequently when he had made microscopic examination, as an instance of fibroid disease with coincident hyper-

trophy. In the Munich cases, however, accurate microscopical examination of portions of the heart-muscle showed no evidence of degenerative or inflammatory disease. It must be questioned, however, whether the more rigid systematic sectioning after the method of Romberg would not in many of these instances have shown some disease of the heart.

The occurrence of acute degenerative lesions of the heart was first indicated by Stokes in 1854, when he described the effects of typhoid and other fevers upon the heart-muscle, but the accurate study of the myocardial degeneration occurring after fevers is more particularly due to the observations of von Zenker. It is unnecessary in this place to enter upon a detailed description of the various forms of degeneration that have been described in fevers and in other conditions. I may, however, name among these conditions parenchymatous degeneration or cloudy swelling of the muscle-fibers, the hyalin transformation of Zenker, fatty degeneration with various forms of destruction of the fibers, atrophy of the muscle-fibers in association with interstitial myocarditis, and the segmentation and fragmentation of the fibers which has occupied so much attention of late. Until quite recently the opinion was generally held that the form of disease occasioned by infections is usually degenerative. The investigations of Leipzig pathologists, including Romberg, Krehl, Pässler, Kelle, and others, have shown that acute myocarditis is the condition usually produced and that this form of disease of the heart-muscle is practically always present in fatal cases of diphtheria, scarlatina, typhoid fever, and other acute infections. In cases in which the symptoms during life have indicated distinct disturbance of the heart's action, the changes in the heart-muscle have been correspondingly marked, but systematic studies have shown many instances in which there were no clinical symptoms and in which even the macroscopic inspection of the organ presented no evidence of disease, and yet in which the microscopic examination of serial sections has discovered localized or diffuse myocardial change. The termination of these conditions cannot, of course, be studied directly, but all analogy would indicate that the recovery from inflammatory and degenerative lesions of the myocardium of this sort could only be in resolution or the development of fibroid areas. If this were true, an explanation would be offered for the development of some of the cases of chronic myocardial degeneration of fibroid character whose etiology up to the present time has been obscure. It is not to be supposed, however, that all instances of fibroid heart have this origin. The interesting contributions of Dehio of Dorpat may be cited in this connection. Dehio described the fibroid changes of the heart with particular care and applied the term "myofibrosis" as descriptive of the condition. Further he advances an interesting theory of etiology of the fibroid change in these instances. It will be recalled that Thoma constructed a theory which has been widely accepted as explanatory of the fibroid areas or patches in fibrosis or atheroma of bloodvessels. According to this theory, the localized nodules of the arteries represent attempts on the part of fibrous tissues to strengthen, by their hyperplasia, spots of weakness occasioned by degenerations of the muscular tunics. In the same way Dehio suggests that when the muscle of the heart has become weakened through degenerative disease or functional insufficiency, hyperplasia of the fibrous tissues of a conservative character takes place and main-

tains for a time the resistive power of the heart-walls against dilation. Eventually, the fibrosis becomes insufficient to withstand the intracardial pressure and the remaining muscle-fibers themselves suffer in consequence of the pressure of the invading fibrous tissue, which was in the first instance designed for their preservation and support. Attractive as this theory seems, it cannot be regarded as more than hypothetical.

While there are instances of fibroid and fatty degeneration of the heart-muscle which are obscure in their etiology, the very great majority of instances are clearly traceable to the influence of disease of the coronary arteries, and advanced myocardial disease may usually be assumed to be but one of the expressions of general or local arteriosclerosis. The causes of the latter have been more or less definitely fixed. Whatever ignorance there may still remain regarding the ultimate manner of action of these influences, it is certain that syphilis, alcoholism, laborious occupations with exposure, and gout are among the conditions that are capable of hastening the involution processes of old age in the arteries and of developing the exaggerated form of arterial disease known as atheroma. Among the favorite localities of this process, the root of the aorta and the coronary arteries take high rank, in consequence of which a starvation of the heart-muscle sooner or later follows and degenerative lesions are developed.

The degree of coronary sclerosis, of course, plays a very important part in the extensiveness of the muscular degeneration, but there are other influences that must be taken into account. In the first place, the thought suggests itself that a heart, which has been the seat of infectious myocarditis in early life, and which has, in consequence, been left to some extent damaged in structure, though still quite capable of adequate function, would in later years suffer degenerate change as a result of moderate grades of coronary disease. In the second place, it is not improbable that inherent weakness of the heart, a condition which may be assumed to exist, though it is difficult to demonstrate, may render the muscles more liable to degenerative disease than a normal one. We are but approaching the threshold of knowledge regarding this matter of primitive functional weakness of organs. There does not seem much doubt, however, that some individuals are born with weak stomachs, nerves, livers, brains, or hearts. That influences, which, in the normal man are capable of causing disease of these parts, should more readily affect the congenitally weak organs is a self-evident proposition.

Finally, I wish to call attention to a matter of some and perhaps of great importance. The experiments of Romberg and Pässler have shown that, in the course of infectious fevers, circulatory weakness is especially due to central depression or paralysis of the vasomotor mechanism, and in but a secondary degree to the existence of myocardial disease. In the later stages of such diseases when the fever has subsided, and convalescence has begun, the vasomotor disorder becomes of less consequence, while the organic muscular disease is all-important. There does not seem much doubt of this, even leaving experimental demonstration out of the question. Closely allied with this subject is the matter of disproportion in the cardiac power, and the general needs of the system. Experimental and clinical investigations have demonstrated what at first sight seems most doubtful, that fatty degeneration and overgrowth of the heart affect its functional activity comparatively little; yet there are many instances in which obesity with

fatty heart is attended with signs of a maximum grade of cardiac asthenia. If the size and weight of the heart in these cases is taken into consideration, and compared with the general body-weight, it will be evident that the cardiac power is relatively, though perhaps not actually, deficient. The same thought applies to the investigation of the circulation and of the cardiac power in persons of unusual height. It has been the clinical experience of others and of myself, that men above 6 feet in height suffer greatly from circulatory weakness during and after typhoid fever, and it has often been observed that tall soldiers are less enduring than those below the medium height. The explanation is possibly to be found in the greater demand made upon the heart rather than any special deficiency of that organ.

This brings me to speak of another matter connected with the functional activity of this organ, viz., regarding the so-called reserve power of the heart-muscle. In the condition of entire health, the power of the heart is sufficient to cope with ordinary demands, and on occasion to fulfil unusual demands without unpleasant consequences. When physical strains are placed upon the organ with sufficient frequency, increase of power may be developed, but only in proportion to increased size, or hypertrophy; similarly, when diseases of the heart-muscle, the valves, or the general system have increased the difficulty of circulation, hypertrophy of the heart ensues, but only sufficient to counterbalance the unnatural obstacles. In other words, the reserve power is practically wanting. As a matter of fact, I believe that the fully compensating heart does possess a certain amount of reserve, but this is undoubtedly much less than that possessed by the normal heart. With continued increase of the circulatory impediments, or as a consequence of intercurrent diseases, there must finally come a time when the reserve-power is consumed, and the power fails for even ordinary demands. Evidences of continuous cardiac insufficiency then become so plain that they cannot be overlooked. Before that event, however, the reserve-power may suffice to prevent disturbances, and the patient is unaware of the existence of a cardiac or circulatory weakness.

The nature of this loss of reserve power of the heart is, however, a matter of pure speculation. As I have before noted, Dehio regards the fibroid changes of senility and of cardiac disease as a conservative process designed to strengthen a weakened muscle, and Rosenbach advanced a similar theory. Whether this be true and explicable on the theory that degenerative changes or purely vital processes first weaken the muscle, or whether on the contrary the fibroid change is the primary cause of the loss of cardiac power, it may be taken as an established fact that in nearly all cases of cardiac disease, including acute inflammations of the endocardium and pericardium, in chronic valvular disease and the so-called idiopathic enlargements, disease and consequent weakness of the heart-muscle is the essential lesion from the point of view of progressive insufficiency of power. This consideration necessitates a change of attitude toward these diseases. The predominating importance of the mechanical impediments in the form of the valvular lesions or arterial obstructions, which has so exclusively engaged attention since the time of Bouillaud and Freysig, must be abandoned, and the heart-muscle must hereafter be given a greater share of attention in prognosis and treatment. The diagnosis of the future, as Jürgensen remarks, will not be endocarditis or pericarditis, but pancarditis. An

objection to this term might be recorded, as proofs are wanting that the condition of the muscle is an inflammatory one, but the general thought is uninfluenced by this exception.

It is necessary to add a few words regarding the role of the nervous system. The tendency of recent times has been to minimize the importance of the intracardiac ganglia and the central nervous mechanism, and to assign a greater importance to the automatic contractility of the muscle. His and his associates have demonstrated the rhythmic contractions of embryonic hearts at a time when the intracardiac ganglia and the nerves have not yet developed. The important function of the nervous mechanism is a regulatory one; heart-rhythm is more immediately dependent upon the nervous integrity than is heart-power.

Having pursued this subject to such length let me recapitulate in a few words the succession of events which I desire to establish. At the beginning of the century the occurrence of cardiac hypertrophy under certain conditions was recognized, but the causes of the hypertrophy were not even remotely guessed at; the mechanical influences that operated to produce dilation were somewhat more clearly appreciated. Bouillaud first established the importance of valvular lesions as the causes of hypertrophy. Subsequently the effects of functional overwork in developing cardiac enlargement followed by irritability and weakness were appreciated, and still later the frequent occurrence of organic lesions as the foundation of these weakened states. Only in the last decade has the frequency of myocardial change in infectious diseases of all sorts been appreciated, and the relations of the general vasomotor system and the functional demands to cardiac power been properly understood.

We find ourselves then at the present day confronted by an entirely new problem, the search for the ultimate causes of muscular weakness and degeneration of the heart, fully realizing the multiplicity of causes that play a part. This is no unimportant task, for experience and statistics alike indicate a growing frequency of disorders of the circulation. Hirsch points out in his *Geographical Pathology* that the number of cases of disease of the heart increased enormously in France at the end of the eighteenth century and in the troubled times of 1830; as well as in Italy in the revolutionary year of 1848, and in Sicily, in 1860. Though the increase during the French Revolution could with much probability be ascribed to the prominence of Corvisart and his teachings, it is not unlikely that the troubled times and the general unrest of mankind played an important part. Were this the case, and were it fully established that physical overwork operates to cause cardiac disease, we should naturally expect to find an increase in circulatory diseases in these modern days of active life and wasteful expenditure of nervous energy. The statistics of our census seem to bear out this view, though I am free to admit the unreliability of statistics of any source in matters of this kind.

DISEASES OF THE CIRCULATORY SYSTEM, INCLUDING HEART DISEASE.

The census of 1850 showed..... 991 per 100,000 deaths.
The census of 1860 showed.....1999 per 100,000 deaths.
The census of 1870 showed.....3460 per 100,000 deaths.
The census of 1880 showed.....3971 per 100,000 deaths.
The census of 1890 showed.....5569 per 100,000 deaths.

It must, of course, be admitted that such figures are likely to be misleading for several reasons. In the first

place, as is pointed out by Dr. Billings in his general review of the statistics of 1880, such diagnoses as dropsy, asthma, etc., which formerly figured so largely in census reports, have disappeared, and the causes of these symptoms have become more generally known, with a consequent increase in the number of circulatory diseases. Again, it is likely that obscure cardiac diseases are more frequently recognized as such than formerly, but when all of the facts are considered, it is not improbable that the number of diagnoses of cardiac and circulatory diseases has suffered diminution as well as increase through wider knowledge.

The opinions of physicians of large clinical experience seem to establish a fairly presumptive claim to increase in the frequency of cardiac disease. One factor of importance in this connection is that of average longevity, and while the statistics in this connection are little less reliable than those above cited, it seems more than probable that the average length of life has increased materially during the present century. On this assumption it would be easy to understand that cardiac diseases (at least those of a dangerous sort) had increased during the same period. It is needless to enter into this subject more extensively; my reason for introducing it at all was to emphasize the importance of attention to the form of disease under consideration, as it is quite likely that the purely muscular diseases have increased more extensively than valvular disease.

In taking up the discussion of the clinical side of cardiac disease, I do not wish to enter upon any consideration of valvular disease, though the relations of the cardiac muscle to the valvular deficiency is of the utmost importance; but it is of even greater consequence for us to appreciate the frequency of cardiac diseases affecting the heart-muscle in particular. Valvular diseases are not readily overlooked, because even in the beginning when active symptoms are wanting, a casual examination may disclose the nature of the disease by reason of the presence of murmurs. In muscular diseases of the heart, however, it is unlikely that any physical signs would be present during the earliest stages, and the disease approaches in an insidious manner and cripples the cardiac power before the clinician becomes aware of the nature of the patient's malady. If, however, anything is to be accomplished in the way of medical aid, it must be in the forming stages, before the degenerative lesions have increased to such a degree that an arrest of the process would leave the cardiac power insufficient for the ordinary needs of the circulation. In the closing paragraph of his book on cardiac disease, Corvisart points out the uselessness of treatment as far as the cure of the local conditions is concerned, and expresses the hope rather that the future may disclose means of early recognition and at the same time of prophylaxis whereby the frequency of cardiac disease may be reduced. I have alluded to the frequent occurrence of myocardial lesions in the course of the acute infectious diseases. It is very evident to the student of pathology that complete resolution cannot occur in such cases unless the organ is placed under the most suitable conditions; that is to say—unless the maximum amount of rest is enjoined. It follows that if we are to reduce the frequency of muscle-disease of the heart in later life, we must see to it that the convalescence of the acute infectious diseases of childhood and of early manhood is conducted with great care. I have often observed that young men after typhoid fever suffer more or less circulatory weakness and insta-

bility for as much as a year or eighteen months after their recovery. It is altogether likely that during this time the lesions of the myocardium, as well as other lesions throughout the body, are undergoing slow resolution, and it follows that any excess in the way of mental or physical strain during this period might delay or stop all effort at resolution. After an apparently complete recovery, it seems not improbable that the myocardium still may remain in a morbid state insufficient to cause clinical symptoms but sufficient to initiate progressive disease in subsequent years when strain has begun to tell upon the organism as a whole.

The onset, however, of such myocardial disease is always insidious, and after its full development and clear recognition it will usually be impossible to determine the exact date of beginning. There is one set of phenomena, however, which is of great importance and which probably more often foreshadows the developing disease than any other symptoms. Unfortunately these signs are of so vague and indefinite a character that they do not suffice to localize the disease in the absence of other indications. I am now referring to the peculiar loss of vitality and strength which characterizes most of the cases of progressive myocardial degeneration. This is so gradual in its development that it is more often ascribed to increasing cares and to advancing years than to the real cause. Most of the patients suffering with the disease under consideration are above middle age and the majority of them are of the male sex. The more pronounced instances occur in men who have led active business lives, and who have subjected themselves to repeated or continuous strains. When we see in such persons a falling off in activity, a disposition to be less interested in affairs, a loss of strength of a purely physical kind, especially when the individual shows some loss of color, a premature grayness of the hair, and that peculiar yellowish-whiteness of the face, combined with slight injection of the venules, which is so characteristic of atheroma as to be called the atheromatous facies, we are justified in suspecting a deep-seated, vital, morbid process, and should not overlook the heart as a frequent seat. As an instance of the indefiniteness of onset, I recall the case of a physician who died of angina, and who had been suffering for some months with vague symptoms indicating progressive loss of vitality. His daughter, who had watched him very closely, and who really suspected the serious nature of his disease long before his physician, noted his disinclination to assume tasks which formerly seemed easy, and in particular called my attention to an occasion when her father had remained at home on account of the weather, which was not more than ordinarily severe, and which in previous years would have caused him no inconvenience. He was not suffering with any acute trouble at the time, and his daughter's reference to it was simply to illustrate his gradually increasing loss of energy.

It would be impossible, however, from symptoms of the sort above indicated, to arrive at a positive diagnosis of myocardial degeneration. They would serve only to indicate a progressive malady of a serious kind. The first and most significant localizing sign to which I wish to call attention is irregularity in the pulse and in the heart action. Intermittency and irregularity of the pulse may be due to reflex disturbances taking their origin from the stomach or other organs, or they may be the consequence of overuse of tea, coffee, tobacco, or alcohol; but in persons above the age of 40, such

explanations of the occurrence of cardiac arrhythmia should be accepted only with the greatest care. Much more frequently it will be found in the course of time that the reflex disturbance or the toxic cause of the irregularity was simply a spur to the more serious organic disorder of the heart which was the essential cause of the irregular action.

Some attention has been paid of late to a disproportionate weakness of the pulse as compared with the apex beat. This has been referred to as a sign of dilation of the cardiac chambers in consequence of myocardial weakness. There can be no doubt of the correctness of the clinical observation—that in many instances of progressing myocardial weakness the pulse becomes excessively weak, while the apex beat remains strong, and sometimes indeed becomes extraordinarily vigorous and extensive; but this sign is not often present in striking form in the early stages.

In the same connection I would call attention to the fact that abortive systolic efforts on the part of the ventricle are not infrequent even in the earlier stages of myocardial disease. These occur in their most pronounced type in the later stages of fibro-fatty heart, but may, as I have just said, occur even in the beginning, particularly if care is taken to examine the heart's action after prolonged effort or after nervous strain. At such times the disturbances of action are heightened and an early diagnosis may thus be assured. In the more pronounced cases, it will be found that the cardiac sounds indicate a much greater frequency of ventricular systole than the pulse, as many of the contractions are insufficient to produce a palpable pulse. In the less pronounced types there is merely a weakness of some of the pulse-beats, so that apparent intermittency is occasioned. In such instances the sphygmograph may show the slight or abortive systolic efforts.

Another symptom of importance, and one which has not been especially described, is the tendency to relaxation of the skin. In many cases of myocardial trouble, I have found that for some time prior to the development of distinctive symptoms, there has been a tendency to a relaxed state of the skin with copious sweat, which has sometimes occasioned diagnoses of rheumatism, post-influenzal debility, etc. Whether this phenomenon be a vasomotor reflex, whose ultimate purpose is relief of the heart from strain, or whether the condition may be the result of extended peripheral vascular weakness is an unimportant matter from the clinical point of view. The symptom, however, is significant, though by no means indicative of a definite malady. I mention it here only because of its obvious relations to other vascular phenomena, though it is far less significant of an underlying cardiac disease than are the other vascular symptoms to which I have referred.

I have before made reference to a pallor as among the symptoms of increasing cardiac weakness, but I wish to dwell upon this more particularly. In advanced cases of myocardial degeneration, and especially in those cases dependent upon arteriosclerosis, the color of the skin grows progressively more pallid, and in the face this has an almost characteristic distribution and appearance. The first evidences are seen about the mouth and nose and over the temples and in front of the ears, and the pallor is apt to be increased by general fatigue and nervous depression. A sudden fright in particular is likely to cause a distinct change of color, and this may persist for a long time instead of rapidly disappearing as would be the case in an individual in

good health. In the later stages the pallor increases in extent, and eventually the whole face is involved, though as a rule some color is preserved in the cheeks until a very late stage in the disease. This change of color, together with the change of disposition caused by a gradually increasing loss of vital energy, leads to such a marked general change in the individual that sooner or later the family, and finally the friends and acquaintances are struck by it. All of these changes, however, are so gradually produced, and are so frequently ascribed to increasing cares or increasing years, that the real underlying cause is apt to be overlooked until a stage has been reached at which the most casual observer is shocked into an appreciation of the serious condition of affairs.

I wish to make allusion to another vague, indefinite, and only very slightly reliable symptom, viz., the variability in the specific gravity of the urine. This is marked in cases in which there is widespread arteriosclerosis. It is less likely to occur in other forms of myocardial disease. I have, however, been frequently struck with the changing specific gravity of the urine in persons with increasing arterial sclerosis, at a stage of this affection when albuminuria and other more definite indications of interstitial change in the kidney have not yet made their appearance. Of course it is scarcely necessary to refer to the fact that the amount of liquid consumed by patients to some extent governs the excretion of urine, and therefore the specific gravity of this fluid. It is, however, a matter of daily clinical experience that normal persons, living a uniform life, excrete urine of more or less uniform specific gravity. When, however, arterial disease has begun, I have frequently observed a marked variability, so that while the morning urine is not rarely heavy, giving a specific gravity of from 1.010 to 1.025, the evening specimen showed a specific gravity of from 1.005 to 1.010, notwithstanding the fact that the amount of liquid taken had not been abnormal. This tendency to rapid excretion of liquid, to which the term tachyuria has been given, is not among the recognized symptoms of early arterial disease, but I am convinced from clinical observation that it will be found to exist in most instances.

One other symptom, or set of symptoms, occurring in the earlier stages of myocardial disease requires special mention. I refer to the gastric phenomena. I recall several instances of men who have suffered with fibro-fatty heart, and who have finally died in anginoid paroxysms, who have presented among the earliest manifestations gastric disorders of one sort or another. To some extent gastric disease in cardiac affections is the result of sluggishness of the circulation and congestion of the mucous membrane of the stomach and gastrointestinal tract. This explanation is especially true of valvular disorders, and in particular of mitral disease. It is, however, of subordinate importance in the myocardial diseases which we are now considering. In the latter cases the gastric symptoms occur so early, are so variable, fluctuate with such marked rapidity, and are of such a character, that another explanation must be invoked. The close relation of the stomach and heart in their innervation needs only to be mentioned. It is on account of this nervous connection, no doubt, that myocardial diseases are frequently attended with painful disorders of the stomach. In one striking instance that has come under my notice, the patient suffered with typical gastralgic attacks for some time and was treated with the idea that the disease was

primarily a gastric disorder. Subsequently the gastralgic attacks became transformed into typical paroxysms of angina pectoris. I have since observed this in several other marked cases.

Next in importance is nausea, which, though far less distinctive than painful seizures, is a great deal more common in the early stages of chronic myocardial disease. It may persist for a long time without vomiting or it may be accompanied by vomiting, but in either case relaxation of the skin and marked weakness of the pulse are usually associated. I have always felt that these gastric paroxysms are attended with relaxation of the abdominal vasomotor mechanism.

In the later stages of myocardial disease, increasing dilation of the chambers of the heart occasions murmurs and changes in the size of the heart which cannot be overlooked by even the most careless observer. Coincidentally with these physical signs, marked symptoms such as dyspnea or cardiac asthma, swelling of the feet, and later, general anasarca, albuminuria, and venous stagnation, proclaim a cardiac disease, but it is unnecessary to refer to these symptoms in detail. A diagnosis at this stage of the affection can have no other value than as confirming or correcting previous impressions. If the treatment is to be of any value, it must be applied in the early stages of the disease.

It is my firm belief that many of these cases may be arrested in the earlier and less serious stages, and that perhaps some restitution may be effected. This, however, presupposes early recognition, and rigid dietetic and general prophylactic measures of treatment. The patient himself does not realize the seriousness of the disease, nor does the physician recognize the existence of the trouble in the early stages. Alertness to the danger and frequency of the condition, however, cannot fail to make its recognition more frequent, and it has been my object to indicate some of the earlier signs, though I am well aware that a positive diagnosis is usually impossible prior to the time when the disease has become incurable and unmanageable.

FRACTURE OF THE CARPUS.

A Study of 52 Cases of Injury in which One or More of the Carpal Bones were Involved.

By G. G. ROSS, M.D.,

of Philadelphia.

Assistant-Surgeon to the German Hospital,

AND

M. I. WILBERT, Ph.D.,

of Philadelphia,

Director of the Radiographic Laboratory at the German Hospital.

MODERN man is largely dependent on his manual dexterity to provide himself and those dependent on him with the absolute necessities and as many of the luxuries of this world as his abilities will admit. It is largely due to this manual dexterity that the more civilized races have been able to make the rapid strides in the mechanic arts that have played so important a part in the development of the resources of the world. The usefulness of the hand is largely dependent on the radio-carpal articulation, or wrist-joint. This is a condyloid articulation with a very wide range of motion, both laterally and also in an anteroposterior direction.

This joint being somewhat complicated, is subject to

a variety of injuries and diseases, all of them more or less difficult to diagnose or to differentiate. Among the more common injuries, what is commonly called "a severe sprain" is probably one of the most unsatisfactory so far as diagnosis and treatment are concerned. This diagnosis is made to fit any case with a history of injury, and in which there is no easily distinguished fracture and no extensive laceration of the muscular and fibrous

FIG. 1.—Diagram from radiograph No. 1757. Shows simple fracture of scaphoid in right wrist, accompanied by some displacement of the fragments.

tissue. While in many of these so-called sprains the wrist is restored to its normal condition in a reasonable length of time, there are, however, others that give more unsatisfactory results, have a very prolonged convalescence, and a persistent, or sometimes an acquired, interference with full use of the joint. These latter cases are sometimes classed as cases of chronic rheumatism. A careful study of a number of these so called cases of "severe sprain of the wrist" that have come under our observation during the past two years, has brought us to the conclusion that many of them are really more or less extensive fractures of one or more of the carpal bones.

The clinical features of a fracture of the carpus are not definite nor well defined. The usual history is that of a fall or of having been hit on the palm or sometimes on the back of the hand. Pain is usually present, though seldom severe. There is generally more or less swelling, and while it can hardly be considered characteristic, the swelling is usually persistent and more marked on the dorsal surface. Crepitus is rarely obtained, as might be expected from the anatomic relations of the carpal bones. There is seldom much if any deformity, although in cases in which there is much impaction, and in which the annular ligament is involved, there is a decided broadening of the wrist. The function of the wrist is always more or less interfered with, due largely to the pain, and in cases of impacted fracture to the mechanical interference of the fragments.

It is generally recognized that the same amount of force applied in different directions will produce different results. This physical truism also applies to injuries about the wrist. Every physician who has met with any number of these cases, must have had his

FIG. 2.—Diagram to illustrate the angles at which a fracture of the carpus or one of the long bones is likely to occur.

attention called to the fact that a comparatively slight fall will sometimes cause a very severe fracture of the bones of the forearm at the wrist, while at other times a similar fall, or what would ordinarily be considered a more dangerous one, will not give any evidence of having caused serious damage to any part of the joint.

It is among these latter cases that we usually find, on more careful examination, a fracture of the carpus. Fig. 1 will illustrate a case of this kind.

The patient, a young man 35 years of age, fell from a bicycle several days before applying at the hospital for treatment. He gave a history of having struck an obstruction while riding along a country road, and of having been thrown off his wheel; as near as he could remember he struck on the palm of his hand. The wrist did not pain him much at the

Fig. 3.—Diagram from radiograph No. 1759. Fracture of the os magnum, scaphoid, and styloid process of the radius.

time, as he claims to have remounted his wheel and ridden home, a distance of 12 or 14 miles. The wrist getting steadily worse, he was induced by one of his friends to paint it with iodine. This did not relieve the pain, and the following day he decided to consult a surgeon. When examined at the German Hospital he presented a wrist that was decidedly swollen and painful. A careful clinical examination did not reveal any evidence of a fracture. On account of the nature of the accident, and also on account of the pain and swelling it was thought advisable to make an examination by means of the x-rays. The resulting radiograph showed a transverse fracture of scaphoid, with slight impaction.

This leads us to say a few words as to the mechanics of these fractures.

The mechanics of a fracture of a carpus are closely related to those producing what is commonly called a Colles' fracture, the two occurring under very similar conditions, and with but a slight variation in the direction of the applied force. Fig. 2 will illustrate this point. If we allow the line A, B to represent the hand as it strikes the ground, then in case the arm should form the angle as described by A, B, D, we would probably, as the result of the fall, have a fracture of the lower end of the radius, for, as will be readily seen, the impetus or force would be transmitted by the metacarpal and carpal bones squarely, striking the lower end of the radius at an angle which generally results in a chipping off of a more or less extensive portion of this bone.

In case, however, the forearm and hand describe the

Fig. 4.—Diagram from radiograph No. 2256.—Fracture of the scaphoid and semilunar, accompanying a fracture of the lower articulating surface of the radius, and a fracture of the styloid process of the ulna.

angle A, B, C, with the hand either in full extension, or full flexion, it will be easily seen that we would have the bones of the forearm placed to the best advantage, and in this case we would have one of two things, either a fracture of one or more carpal bones, or a fracture or luxation about the elbow.

In children we are more likely to have the injury about the elbow, while in adults, in whom the elbow has become more solid, the damage is more likely to occur at the lower extremity. Here it is a fracture of the scaphoid that is the most common of the simple fractures of the carpus. This fracture may vary from a so-called sprain-fracture, caused by the tearing away of a very minute splinter of bone by the attached ligament to a complete transverse or impacted fracture of the bone itself. The latter fracture is no doubt caused by the os magnum being forced into the scaphoid, striking that bone on the lower or inner side of the arch, thus breaking it in the line of least resistance.

The fractures of the other carpal bones are no doubt caused in very much the same mechanical way, practically hammered or split in half between 2 other bones that for the time being are stronger, or have a relatively more favorable position in reference to the direction that the lines of applied force are traveling. The carpal bones that have been found injured in this series of cases are the scaphoid, the os magnum, the semilunar, and the cuneiform, either in combination or alone. The number of times that the scaphoid seemed to be the principal bone involved was in 18 out of a total of 33 acute or recent cases.

Every one will admit, that, to be able to treat any injury or disease in a rational or satisfactory way, it is of the greatest importance to know exactly the nature or location of the injury or disease. With a complete

Fig. 5.—Diagram from radiograph No. 2796. Shows a sprained fracture of the scaphoid in left wrist, and an old ununited fracture of the styloid process of the ulna in the right wrist.

and satisfactory diagnosis the rational treatment of an injury is very much simplified. This is to a large extent due to the confidence that is inspired by knowing exactly the ultimate results to be obtained by treatment. The reason, no doubt, that more of these fractures have not been recognized, even by means of the x-rays, is that many of them are somewhat obscure, the lesion not being extensive and there being little or no displacement. The lines of fractures are sometimes more or less hidden, and are seldom easily recognized in the somewhat complicated shadows cast by the normal carpal bones.

The safest, or rather the only, way to get a satisfactory picture or positive information, is to take both wrists on the same plate under precisely the same conditions. This may be readily accomplished by covering one-half of the holder containing the photographic plate by a piece of sheet lead. In this way we can expose one wrist on the uncovered portion of the plate, then by covering up the exposed portion of the plate, and moving it so as to bring the unexposed portion to occupy exactly the same position under the tube that the exposed portion had, we can obtain a radiograph of the other wrist, in practically the same plane. If we now develop this plate sufficiently to bring out all the minor details, we will have a negative that may be readily studied, and by carefully comparing the two

wrists bone for bone, we can easily distinguish and detect even comparatively slight differences. This plan is illustrated in Figs. 1 and 5. These diagrams are outline drawings from the original negatives, and demonstrate the advantages of the plan very well.

There are several minor details that we must not lose sight of. A very slight change in the relative positions of the wrists will produce a corresponding change or

FIG. 6.—Diagram from radiograph No. 2097. Shows a comminuted fracture of the scaphoid.

apparent difference in the shadows of the resulting radiograph. Even normal wrists may show a slight difference in the development of the various bones or in their densities. We have seen several cases in which, even after a number of years, no bony union had taken place between the fragments. A case of this kind is apt to be mistaken for a recent fracture unless we take into consideration the history and also the clinical symptoms.

Fracture of one or more carpal bones may accompany a fracture of any of the related long bones of the hand or wrist. Or, as in several cases that we have seen, the fracture of a long bone may be secondary to that of a carpal bone and may be produced by muscular energy, such as a fracture of the styloid process of the ulna. This latter fracture is probably produced in a similar way as is the corresponding fracture when it accompanies a fracture of the lower end of the radius. The injury of one or more carpal bones, in connection with a fracture of one of the long bones, was noted in 9 cases. Figs. 3 and 4 illustrate cases of this kind. Both of these injuries resulted from falls from a considerable height. Fig. 3 is taken from a radiograph of the right wrist of J. R., 42 years of age, who fell from the roof of a shed, a distance of 12 or 14 feet, striking the palm of his hand. In this case the force was probably a glancing one, and the direction seems clearly indicated by the three bones involved, the os

FIG. 7.—Diagram from radiograph No. 2345. Comminuted and impacted fracture of the scaphoid, caused by a blow on the palm of the hand.

magnum, the scaphoid, and the styloid process of the radius. Fig. 4 is from a radiograph of the left wrist of J. S., 23 years old, who was admitted to the German Hospital on October 21, 1899, with a fracture of both wrists. The right wrist had an impacted fracture of the radius and a fracture of the styloid process of the ulna, while the left wrist, in addition to the fracture of both

long bones, showed a fracture of the scaphoid and the semilunar.

Writers on the subject of fractures, as a rule, content themselves by speaking of fractures of the carpus as being very rare, and usually caused by direct violence, such as a crush between heavy weights. According to the observations that we wish to record here, neither of these remarks can be accepted as being absolutely correct. We have seen in less than three years, 52 cases in which one or more of the carpal bones had undoubtedly been injured at some time, and in which the patients were at the time suffering pain, or were being inconvenienced by the injury or its effects.

The patients who applied for treatment within two or three weeks of the initial injury, we may class among acute cases. These numbered 33, or a total of more than 20% of all the fractures involving the bones of the hand and wrist, and nearly 5% of all the fractures that were treated at the German Hospital during that time. Of the chronic cases, 19 in number, some were of more than twenty years' standing. One case in which the wrist had been sprained nearly 25 years ago, still showed the initial lesion to have been a fracture of the scaphoid. In this latter case there was apparently more or less motion between the two fragments, and this probably accounted for the persistent pain and inconvenience complained of by the patient.

As to the statement that fractures of the carpus are

FIG. 8.—Diagram from radiograph No. 2847. Fracture of the scaphoid, also shows a deformity of the ulna following a fracture of that bone, and likely to be mistaken for a pathological condition in a clinical examination.

usually caused by direct violence, the histories gathered from 52 cases give but 9 in which there is a clear history of a blow or crush at the carpus. Five gave a history of having been struck on the palm of the hand, the missiles varying from a steamhammer in one case to a baseball bat in another. In 19 cases the patient gave a history of a fall on the palm or back of the hand, the distance in each case not being more than about six feet. In 13 cases there was a history of having fallen either a considerable distance, or from a moving object. In 6 cases no definite or satisfactory history of the initial injury is on record. The latter are among the chronic cases in which the radiograph was taken to discover the cause of a persistent ankylosis or necrosis. Among the patients enumerated, there were 15 males and 7 females. The right wrist was involved in 30 and the left in 22 of the cases, while the age of the patients varied from 15 to 66 years.

The following table gives the approximate ages of the patients when under treatment:

Age.	15-19.	20-29.	30-39.	40-49.	Over 50.	Total.
Acute...	6	11	5	7	4	33
Chronic	2	6	4	3	4	19

A cursory glance at the appended age-table of the cases reported here will impress us with the fact that this injury would seem to have a tendency to occur during the age of an individual's greatest usefulness, or at the time of his greatest earning capacity, so that, from an economic point of view, the proper treatment of these cases should be of great importance.

A few cases to illustrate the various types of injury will not be out of place here.

Fig. 5 illustrates a case of "sprained fracture," an outline drawing from the radiograph of J. S., 66 years of age, who, several days before he applied at the hospital for treatment, was run into and knocked down by a bicycle. He complained of considerable pain in the left wrist, especially on motion; the wrist was also slightly swollen. A radiograph of the left wrist showed a separation of a very small fragment of bone from the outer edge of the scaphoid, while the accompanying radiograph of the right wrist seemed to show a fracture of the styloid process of the ulna. Here is a case in which the simple "say so" of the radiograph would be misleading. Upon inquiry it was found that the patient had sprained his right wrist some 30 years before, the joint was a long time in regaining its usefulness, but, as the patient put it, "had given him but little trouble of late years."

Fig. 6 represents a comminuted fracture of the scaphoid, the history as recorded in the case-book is terse. J. B., 30 years of age, while chasing a horse, fell over a dog, striking on the palm of his hand; supposed to have sprained his wrist.

Fig. 7 shows an impacted fracture of the scaphoid. The patient in this case was at work at a steamhammer, and in

thrititis at the wrist-joint is rare. The x-rays, in these cases, are also of great value, by showing the ulceration or destruction of the cartilages. Even in well-advanced cases when there has been more or less destruction or necrosis of the carpal bones themselves, the resulting radiograph would still distinguish between an old fracture through the body of a bone, and a necrotic process following the destruction of the cartilage surrounding the bone. In the case of a fracture we would have a more or less clean break of the bone, with inflammatory exudate surrounding it, while in the case of rheumatoid arthritis, we generally have a more or less irregular breaking down of several of the carpal bones.

The arthritis following the prolonged immobilization of the wrist-joint, for a fracture or other injury about the lower end of the forearm. This, unfortunately, is a form of arthritis that is not infrequent with the general practitioner, who, in many cases seems to think that it is necessary to tie up a fracture at the wrist for six weeks or two months so as to get good union between the fragments, before allowing the patient to use the arm. In these cases the radiograph usually shows a more or less general diffusion of inflammatory exudate throughout the carpus. This, of course, may ultimately break down and will then present the same necrotic appearance that we see in the advanced cases of rheumatoid arthritis. The history of an injury, or the finding of an old fracture of one of the long bones at the wrist, will aid materially in distinguishing this form of arthritis from either of the others.

In fracture of the carpus there is seldom any displacement, consequently no replacement is necessary; and while it is undoubtedly true that the injury is seldom extensive, still the recognition of the lesion is of great importance, so as to be able to prevent by rational treatment the sequels that are likely to follow injuries about a joint.

A word as to the treatment—the wrist must be kept quiet for from two to three weeks, so as to allow the repair of any injury to the soft tissues, then careful massage should be used. This in fractures of the carpus is of very great importance, as it has a tendency to facilitate the absorption of inflammatory exudate that is generally thrown out quite freely at the seat of fracture, and especially if the fracture involves a joint.

SOME PHASES OF THE TUBERCULOSIS PROBLEM IN COLORADO.¹

By S. G. BONNEY, A.M., M.D.

Professor of Medicine, University of Denver; Visiting Physician, St. Luke's Hospital.

THE present interest attached to this subject, with its vital relation to pulmonary invalids as a class and to the resident population of Colorado as well, renders it fitting and opportune to call attention to a few practical considerations concerning the rationale of the problem and methods of solution.

There exists in Colorado not only an appreciation of the communicability of tuberculosis and the necessity for rational preventive measures, but also, unfortunately, a somewhat unreasoning fear as to the dangers of direct infection, despite strict conformity to recognized precautionary steps. There has developed an increasing

FIG. 9.—Diagram from radiograph No 1993. Old fracture of the scaphoid, with displacement of fragments and considerable inflammatory exudate or callus, involving the styloid process of the radius.

putting up his hand as a signal to stop the machine, was hit on the palm of the hand by the falling hammer.

Fig. 8 is probably particularly interesting only from the peculiar callus or growth on the ulna, the result of an old fracture of that bone 17 or 18 years before. The fracture of the scaphoid in this case is a simple one, though there is more than the usual deformity. The patient gave a history of falling on the palm of the hand, and complained of much pain. In this case the physical examination was misleading, as the callus on the ulna was mistaken for an acute condition.

Fig. 9 is an outline tracing from an old case of injury to the scaphoid. The patient, L. L., 35 years of age, came to the hospital on July 7, 1899, with a history of having sprained his right wrist some 9 or 10 years before, by falling on the palm of the hand. At the time, the wrist was very painful, and it has given him more or less trouble ever since. He has been treated repeatedly for what was supposed to be rheumatism. During the past 2 or 3 years the joint has become progressively worse, and when admitted to the hospital was much swollen, inflamed and practically ankylosed. The patient said the joint had been in this condition for several months, and that he has not been able to use the hand for several years. The diagnosis in this case was an arthritis caused by persistent irritation and the consequent inflammation of the joint. There was also some necrosis and breaking down of the fragments.

There are two forms of arthritis that are apt to be mistaken for one following a fracture of the carpus. These are:

Rheumatoid Arthritis.—Here the previous history is of great importance, an initial attack of rheumatoid ar-

¹ Read before the American Climatological Association at Washington, D. C., May, 1900.

popular prejudice against the ordinary association with the consumptive, and a beginning sentiment against the further importation of individuals afflicted with the disease. The early feeling of apprehension among the people with reference to what appeared a somewhat mysterious but ever-present danger of contagion has grown to a sense of alarm. The agitation originally conceived through scientific knowledge applied to public health, is giving birth to a somewhat ill-proportioned and ignorant crusade. There result embarrassing difficulties in the way of securing adequate accommodations for the consumptive, and much unnecessary humiliation, with lack of moral encouragement, to those entitled to every sympathetic consideration.

Have the actual exigencies of the situation been sufficient to justify in the interests of society the development of a somewhat immoderate professional attitude and an intolerant popular sentiment? Is it not well to propound a deliberate inquiry from an impartial standpoint relative to their causes and justification?

My position is defined with emphasis in hearty support of the admirable efforts of the health authorities, and with contempt for the indifference of those who refuse to cooperate in the rigid enforcement of regulations tending to the restriction of the disease. I am not in sympathy, however, with an agitation not warranted by the facts and tending to create alarm. While the attraction of our climatic conditions has become a serious question for our resident population, it is apparent that the present local sentiment is but partially justified by actual conditions.

Public attention has been repeatedly drawn to statements emanating from the Health Departments relative to the increasing number of cases of pulmonary tuberculosis reported to have originated in Colorado. Unequivocal interpretations have been promulgated by some physicians to the effect that the source may be ascribed to direct contagion, and that as a logical deduction tuberculosis is likely to become an important indigenous disease in Colorado, entailing future ruinous effects upon her communities. I am unable to accept the evidence presented to substantiate the alleged increase of consumption contracted in Colorado, and submit that the data as yet introduced are altogether too meager to warrant such conclusions.

Some years ago, in presenting a paper before the Colorado State Medical Association, I protested against a popular premature verdict concerning this subject. In support of my position then taken and, I believe, now to be confirmed, I will refer very briefly to portions of my previous article, with such statistical addenda as have been furnished subsequently.

"A review of the material offered as evidence to establish the large proportion of cases developed in Colorado to those contracted elsewhere, indicates that the chief source of information is found in the records of the Denver Health Department. In the annual report for 1896 it is stated that the number of deaths during the past year from tuberculosis developed in Colorado 'is a little more than $\frac{1}{4}$ of the total tubercular death-rate.' It is also noted that the percentage of deaths from tuberculosis contracted in this State has been progressively increasing. In 1893 the proportion is stated to be 11 $\frac{1}{4}$ %; in 1894, 13.7%; in 1895, 15%; in 1896, 18.4%."

Later reports from the Health Department show the proportion in 1897 to be 18%, and in 1898 19.7%. The source of information upon which these statistics have

been compiled has been the returns upon the death certificates.

"I must insist that the *percentage of deaths* is by no means a fair criterion of the proportion in Denver of cases said to have developed in Colorado to those contracted elsewhere. The pulmonary invalid from a distance, with hopeless prognosis, is usually advised to return to his home. Comparatively few of such cases, fortunately, are permitted to die in Denver, removed from family and friends. The proportion, then, of 1 to 6 does not properly apply, as might be inferred, to the existing cases of tuberculosis in Colorado.

"It is easy to demonstrate the fallacy of the alleged rapid increase in the percentage of deaths from tuberculosis contracted here.

"It is apparent that a change may be effected in a given ratio by a change in *either* of its terms. In other words, the percentage of deaths from tuberculosis developed in Colorado may be increased from year to year by reason of an increase in the number of such deaths, the total tubercular death-rate remaining unchanged. Likewise, the proportion is increased if the number developed in Colorado is constant, provided the entire death-rate from tuberculosis is diminished.

"While the figures of the Health Department show the *percentage* to have very rapidly increased, the actual number of cases originating in Colorado is but slightly larger for the four years, while the total number of deaths from tuberculosis is considerably less; thus, of course, effecting an increase in the proportion, but possessed of no further significance. Thus in 1893, the total number of deaths from tuberculosis is reported as 435, of which 49 are specified as contracted in Colorado, establishing the percentage of 11 $\frac{1}{4}$ %. The next year the total number was 377, a diminution of 58, while the number contracted in Colorado was 51, an increase of but 2 cases for the entire year. It is obvious at once that the increase is entirely insignificant, yet the proportion is published as being 13.7%, a gain of 2.5% in the deaths, originating in Colorado for the year."

An analysis of the statistics for 1895 and 1896 gives practically the same results. The number of deaths in 1896 is but 2 more than for 1895, and but 17 more than for 1893, in spite of an increase in that time of 26,000 in our population. Yet the percentage is much increased in 1896 on account of a diminution of 60 in the total tubercular death-rate.

It is of much interest to note that the statistics for 1899 recently furnished by the Health Commissioner are decidedly at variance with those previously reported, and serve to some extent as an official refutation of the alleged rapid increase of pulmonary tuberculosis in Colorado.

Despite an increase of 50,000 in the population of Denver since 1893, the number of cases specified as having developed in 1899 is but 4 more than in 1893, and the percentage of such cases to the total deaths from tuberculosis is but 9.9, about one-half of that reported for the three previous years, and less than any proportion which has been determined since 1893. The compilation of these statistics was based upon the same official sources of information and with the employment of the same methods as in previous years.

The practical significance of a material annual increase in the population has not been considered in the system of computation thus far employed. Admitting the possibilities of error necessarily attending any method of determining the relations of indigenous

consumption, I can suggest none more satisfactory than the proportion of such cases to the population. Accepting the figures of the Health Department relative to the population of Denver, and the number of deaths from primary tuberculosis during the past seven years, the percentage of such deaths per one thousand inhabitants is found to vary but little from year to year, the proportion being less in 1894 than in 1893; in 1896 slightly less than in 1895, and in 1899 0.30% as compared with 0.36% in 1893.

A factor of no inconsiderable importance is the strong inherited susceptibility of a portion of the younger population in Colorado. Manifestly, in view of the special predisposition, such infant cases should not be recorded as instances of deaths from indigenous tuberculosis. A great majority of these are cases of tubercular meningitis, recognized as developing largely from previously infected bronchial glands rather than from external sources.

While, at first thought, observations concerning tuberculosis in the native born appear particularly conclusive, it becomes apparent that they possess but little significance in support of the supposed evidences of an alarming and widespread dissemination of the disease through direct contagion. It seems proper, therefore, to emphasize the fact that, of all the cases reported to have died from tuberculosis contracted in Colorado during the past 7 years, nearly one-fourth were in children under 4 or 5 years of age, 85% of whom died of tuberculous meningitis. In 1897, out of a total of 88 cases of indigenous tuberculosis, 22 were under 4 years, and 19 died of tuberculous meningitis.

A further consideration is the absence of proof that cases, reported to have developed in Colorado, were actually contracted there. Much testimony has been adduced in recent years, demonstrating the extraordinary frequency of unsuspected tubercular infection. Under changed conditions in subsequent life, an active process supervenes, as the individual resistance is lessened. In view of the large number of people who come to Colorado to remain indefinitely with invalid relatives and friends, frequently undergoing hardships and privations themselves, and thereby diminishing their resistance, is it not highly probable that some may develop an active condition from an infection previously latent? The fact that an individual exhibits physical signs of tuberculosis 1 or 2 years after arrival is no evidence that the disease was originally contracted in the State. No case should be thus recorded without recourse to a diligent investigation concerning the history. While, under certain conditions, direct contagion is an accepted possibility in Colorado, as elsewhere, I submit that a reasonable interpretation of official data fails to indicate that consumption contracted there is actually increasing to any extent. If it is, it remains to be demonstrated by statistical observations not as yet introduced.

On the other hand, much clinical testimony has been presented, tending to establish the relative infrequency of such cases. As far as I have been able to observe from the experience of others and my own, there has been in almost every case abundant reason for the development of the disease by virtue of marked inherited taint, the presence of some recognized predisposing cause, environment, occupation, or special exposure. In view of the foregoing considerations, I protest against dogmatic statements relative to the danger of contagion and the spread of tuberculosis in Colorado.

It must be remembered, however, that the influx of consumptives in all stages of the disease and in every condition of financial distress, constitutes an economic problem not to be ignored. The somewhat indiscriminate character of the cases sent to Colorado is not such as to appeal to popular welcome, nor inspire sympathetic and mutually cordial relations. Unfortunately it is the advanced case that is more frequently observed. Many come to the State as a place of last resort, having vainly sought improvement elsewhere.

A reference to my own statistics, previously reported, shows 71% of all the cases to arrive with distinct evidences of tubercular infection in each lung, with a total average period of delay before arrival following the development of the disease of a little over eighteen months.

A large class with no conception of their individual needs, and with mistaken ideas as to conditions found, are hurried to Colorado, impoverished financially, expecting to secure immediate employment. Many are compelled to work for a pittance in order to supply the most pressing necessities; others are doomed to disappointment even in this, and are obliged to seek assistance in order to return home, or become a charge to the State.

Serious hardship is reflected upon the resident employee and his family in being forced to compete with the cheap labor of the unfortunate consumptive in his desperate strait. The frequent spectacle of hopeless cases removed from home, family and friends, tends to inculcate public pessimism and unbelief in the possibility of ultimate arrest of the disease in general, to retard charitable impulses and interested efforts for the relief of those less seriously afflicted.

At the same time the struggle for work and the meager compensation allotted a portion of the population, added to an exaggerated notion of the practical dangers of contagion, serves to awaken a sense of resentment, and to impair to some extent natural humanitarian instincts.

It can hardly be said that the consumptive with such limited resources profits materially from the hardships unwillingly imposed upon others. Whether successful or not in securing employment, the battle for him is necessarily against great odds, and the ultimate disastrous results afford a further commentary upon a state of affairs deplorable, and to some extent avoidable. With added care and discernment on the part of physicians elsewhere as to the character of cases referred, local conditions may be materially modified by a comprehensive system of public instruction and a conservative legislative control.

The first requisite should be compulsory notification and a properly conducted registration of all cases of tuberculosis. This does not imply isolation, personal humiliation, or interference with social or business pursuits. Quarantine for such a disease is neither desirable nor practicable in the interest of either the consumptive or the general community. To be in a position to receive competent instruction from some responsible source, either directly or, when feasible, through the medium of the attending physician, entails no hardship for the consumptive and affords added protection to himself and the public. Whatever burdens might be imposed upon the pulmonary invalid by reason of such a procedure would result purely through public misconception as to the manner in which the infection is conveyed, and exaggerated ideas as to the every-day dangers of contagion.

For such erroneous popular impressions, which have thus reacted to delay the practicability of more thorough protective measures, the medical profession is to some extent responsible, and should in turn apply the remedy; i. e., the inculcation of more complete knowledge. With a capable and humane enforcement of notification and registration laws, there can be directed toward the consumptive and his family and the general public distinctive and separate methods of instruction. The invalid, through whose active and personal cooperation alone can success be attained in the effort for public protection, can be furnished with carefully prepared circular information, explaining the dangers of infection and reinfection, and describing in detail all necessary preventive measures, with an emphatic and insistent appeal for their observance. It is the infected individual to whom special efforts of this nature should be directed, rather than to the community, which is only influenced thereby to an inflamed public sentiment without the accomplishment of practical benefits.

For general distribution, official information should be essentially of a reassuring character. The public should receive instruction from responsible sources concerning the comparatively few methods of possible infection. Full explanation should be made of the exceedingly slight danger of contagion from an intimate and prolonged association with the consumptive under certain precautions, compliance with which prevents him from becoming a source of danger to the community. It should be made clear that the disease never results from a single exposure; that the infection is comparatively slow and incremental in character. Emphatic announcement should be made of the fact that the mere presence of the bacillus is not the sole factor in causing the spread of tuberculosis; but that an element equally potent and necessary is the individual predisposition; that without lessened general resistance and increased vulnerability of the tissues, the soil is not receptive to the bacillus and to infection.

To maintain a high degree of resistance in those already predisposed, and establish greater immunity for all, the argument should be advanced in favor of greater individual attention to mode of life, occupation, and environment, including the hygiene of the home, and a degree of governmental inspection and control, with especial reference to the construction and ventilation of public buildings, churches, schoolhouses, theaters, libraries, tenement-houses, factories, commercial establishments, and conveyances.

The question of legislative interference with marriage and other matters involving the liberty of the consumptive, and disturbing his relation to his family and society, should receive no mention in official public communications as being at present both impracticable and unwarranted. A problem so delicate can never be fairly adjusted by recourse to arbitrary legal enactments based upon the medical principles of marriage selection and social aspect of procreation. More properly is it within the province of the physician in his advisory capacity to exert such an influence as may be indicated in his own judgment and justified by circumstances.

It is not too great an assumption to hope that, with the adoption and intelligent elaboration of such a supervisory and educational system, there may be afforded adequate protection for the community without an abatement of kindly and humanitarian feelings toward a large, afflicted class of our fellow-beings.

RUPTURE OF SYMPHYSIS PUBIS DURING PARTURITION, WITH REPORT OF CASE.¹

By G. A. HIMMELSBACH, M.D.,

of Buffalo, N. Y.

Assistant Attending Physician of Buffalo General Hospital.

In presenting this brief paper, I shall make no attempt to advance anything new or original, but simply to review the clinical history of the case, with some few references as to the literature on the subject. The details of the case will suggest to you the fact, that we as physicians are too often unmindful and, I might say, too heedless, of the possibilities of what at first appear to us normal cases of obstetrics.

Rupture of the pelvic articulation is not new, for it has been known in medicine since the time of Hippocrates. The accident, however, is of unusual occurrence, and this may account for the dearth and brevity of references I have been able to find.

Several able authorities have written monographs on this theme, but, I am sorry to say, that it is too frequently overlooked by obstetrical writers generally.

Probably the most complete work on the subject in the English language is an essay by Dr. Frederick G. Snelling, in the *American Journal of Obstetrics*, Vol. II, No. 3, February, 1870. Parvin says that the accident occurs in labor only in rare instances, and is known as "rupture of the joint." This is preceded by a physiological condition of softening of the articular surfaces, causing a relaxation of the joint. Osteomalacia predisposes to rupture of the joints, but the accident is quite rare in the rachitic pelvis. Pelvic contraction and great size and solidity of the fetal head, and unfavorable position have also been mentioned as causes. He mentions one instance where this accident resulted from the remarkable growth of the trunk of the child, requiring forceps for delivery. I find that in many instances the lesion has been attributed to the use of forceps. Havajewicz found that in 23 cases of separation of the symphysis, forceps had been used in 16.

Renny reports three cases, one in which forceps was used, and in the other two delivery was spontaneous. Ulsamer believes that rupture of the pelvic articulation from forceps is much more frequent than is reported.

Relaxation of the pelvic ligaments during the gravid state also contributes. Someone has said that it occurs, especially in women who have had pregnancies follow one another in rapid succession.

Pategrat says that sometimes there is really no rupture of the articulation, but merely a stretching of the pelvic ligaments. Stoltz, in connection with this, regards the relaxation of the pelvic ligaments as a result of a pathologic process, because the physiologic relaxation in most pregnant women could not possibly produce so wide a separation of the symphysis, as to render parturition more easy. It is then really of a pathologic nature and occurs either spontaneously or suddenly upon the employment of force, or in consequence of extraordinary natural efforts.

In 1875, Ahlefeld collected 100 cases of lesions of the pelvic joints, and in 1888, Schultz added 18 more to this list. Fordyce Barker has an excellent presentation of the subject in his work on "Puerperal Diseases." Trousseau has written an able paper on "Loosening of the Pelvic Symphysis." Snelling states that a certain degree of relaxation of the symphysis occurs in many

¹ Read at the sixteenth annual meeting of the New York State Medical Association, May 8, 1900, at Buffalo, N. Y.

pregnant women which may be regarded as physiologic.

Barker says the ligaments lose their firm and resilient qualities, the synovia is greatly increased and presses the bones asunder; the pelvis becomes incapable of sustaining the body and so gradually yields to the weight above; or some slight and insignificant movement of the patient suffices to precipitate the rupture. He also says there are so many distressing sensations incident to the lying-in period, that if the affection be but slight and nonpersistent, it is most natural to attribute it to the puerperal condition or to some uterine displacement or irritation. Women themselves are so accustomed to vague pelvic and uterine and lumbar pains, that they almost regard them as a natural heritage, and themselves assist in deceiving the physician by ascribing them to the uterine system. In a great majority of cases where this has gone to the extent which constitutes a pathologic condition, the characteristic phenomena are first manifest during the puerperal period.

There is no anatomic reason, so far as is known, why the one sacroiliac symphysis should be more susceptible to the rupture than the other, but from the investigation of Schauta, the accident most frequently involves the pelvic symphysis first, and next in order the right sacroiliac articulation. Rarely the two sacroiliac articulations are affected without the pubic. My case, as will be seen in the appended history, agrees with Schauta's experience, in the fact that both the pelvic symphysis and the right sacroiliac symphysis were injured at the same time.

Renny reports a case in which labor ended without any indication of the injury, but which was made known in some movements of the patient a short time afterward, there having been a "silent rupture." In this respect you will observe that my case again agrees perfectly in that there was no indication of injury, usually manifest by a sudden violent pain in the joint, and moreover there was no accompanying crack or snap commonly heard by those present. Should the injury not be detected at the time of the occurrence or while the patient is in bed, it is recognized when she gets up and attempts to walk. If she succeeds, Trousseau states that she waddles and drags one leg after the other. When the injury is suspected a direct examination of the joint with two fingers or with a thumb and fingers will detect it. It is also stated that if the pelvic articulation is injured, the lower limbs, when the patient is recumbent, will be everted.

In the treatment of this condition, two principles must be observed: first, antisepsis; and, second, immobilization.

Parvin says, if this accident occurs in labor it is important to redouble antiseptic precautions to avert all danger of infection. Dührssen has recorded 33 cases in which suppuration in the joint followed the injury.

The essential treatment, however, is a firmly applied bandage encircling the pelvis, which must be applied sufficiently tight and in such a way as to bring into contact the separated surfaces of the symphysis. A roller towel is a good improvised bandage. The union of the joint may take place in from 10 to 14 days, but sometimes several weeks or even months are required.

The following is a report of my case:

H. G., aged 25 years, primipara taken with pains October 14, 1899, at 10 o'clock A.M. I was called at 10.30 P.M. and found her pains strong, and every 6 to 8 minutes. On

bimanual examination, the external os admitted the index finger freely. The head was found presenting, with sutures and fontanel indicating the first position. The bony pelvis to the examining hand appeared sufficiently large to freely admit the passage of the child without offering any unusual obstruction. No exact measurements, however, either with the hand and finger or the pelvimeter were taken. The vulval outlet appeared very small and the parts rigid and unyielding. At 1.30 A.M. the os had fully dilated and the head began to descend. The pains were strong and at short intervals; the head soon rested on the perineum, and here it remained fully $1\frac{1}{2}$ hours, or until 3.20, when a male child was born; the third stage lasted only 5 minutes. Uterine contractions were good and, all told, a very slight blood loss. Upon inspection a slight median laceration was found, which was restored with silk with a perfect result.

Thus far the labor with the exception of the apparent vulval atresia was to all appearances normal and uneventful. I called at 11 o'clock the same morning and found the patient comfortable, except that she complained of the usual muscle-soreness, which I concluded was from the terrific strain. The next morning I found the patient lying on her back and was told by the nurse that she had found considerable difficulty in turning in bed. I paid little heed to this complaint, thinking that it was simply due to fatigue or muscle-tire. On the following morning, however, the nurse again called my attention to the fact of her patient's disinclination to move, and at the same time said that the soreness was localized to two areas, one in the pubic region and the other in the right hip posteriorly; and, moreover, the nurse wished me to explain to her why every time her patient attempted to turn on to her side, a loud crack or snap was heard, as if two bones were forcibly separated.

The snap was audible at a distance of several feet from the bed, and was not only heard by those present but was distinctly and painfully felt by the patient. This aroused my suspicion and I at once sterilized my hands and made a digital examination of the parts. I found the labia considerably swollen, which was not unusual, but by placing my hand firmly against the symphysis pubis and having my patient turn gently, a separation of the two bones was very plain; one pelvic bone would glide up and down over the articular surface of the other, according to the direction the patient was turned. My attention was now called to the sacral region, and here I found a swelling and ecchymosis over the right sacro-synchondrosis; my hand placed against this region elicited none of the motion that was so plain in the anterior joint. I had never seen a similar case, but my common sense told me that strict asepsis of the vulval region and immobilization of the hips were indicated. A strong and broad bandage, extending from below the breasts to one-third way down the thighs, was immediately applied, and the patient was warned to remain on her back and to move only when the functions of the bowels and bladder compelled her. Strange to say, all of this pubic disturbance did not interfere with her bladder function. My patient was kept on her back for 24 days; during this time I felt certain that the damage was being slowly but surely repaired. On the twenty-fourth day I felt safe in elevating the shoulders in bed, changing somewhat the position of the body, but not applying much pressure on the pelvic organs.

On November 8, I felt safe in lifting her into an inclined chair, but standing on her feet was interdicted for some time thereafter. When standing and locomotion (with support) was first permitted, the pain in

the pubic region was distressing, and this signal warned us to postpone further activity. For a couple of weeks more she was assisted from her bed into a reclining chair. Gradually, but cautiously, she gained her footing and the power to walk; but nearly two months elapsed before she could walk, and then only with considerable discomfort. Particularly was this so when she felt well enough to respond to the front door bell and attempted to climb the stairs, bearing her full weight alternately on one hip and then the other.

I saw her March 15, five months after the confinement; her gait was even (not waddling), but she still complained of pain at times.

CONCERNING CALENTURA.

By FRANK W. FOXWORTHY, M.D.

Captain and Assistant Surgeon, 34th U. S. Infantry, Lavag, Luzon, P. I.

In tropical countries the term "Calentura" embraces anything from pernicious malarial fever to a simple pyrexia, and the natives often designate any febrile condition as calentura. But strictly it should be limited to that fever occurring usually during the months of December, January, and February, which exhibits the symptoms of a simple continued fever with a small mortality. It has been called tropical fever, gastric fever, remittent and intermittent malarial, and even abortive typhoid fever. The symptoms as shown in this country are usually a sudden rise of temperature to 104°, 105°, or even to 106°. This may or may not be accompanied or preceded by a rigor. In my experience it was not in 90% of the cases. The patient has the headache, malaise, furred tongue, anorexia of a high fever. In cases with temperature over 105° vomiting is usually present. Pains in the back, chest and legs are present. The patient complains of these pains, or of the intense soreness he feels, more than he does of his headache. He can't endure much jolting and groans with pain at any sudden movement. Some speak of the pains as resembling the ones present in la grippe. Others speak of the soreness of the back as of a soreness from a severe beating, while in some the feeling is as though their back was broken. In these cases the site of the pain is located in the lumbar muscles. In 80% of the cases here the pain is confined to some portion of the back. In the remaining cases the chest and legs are included. There is no rash or eruption of any kind and there is no definite time for recurrence of the fever, and no diarrhea.

In southern and central Luzon predisposition to the fever was especially marked in those who had insufficient covering at night. As the soldiers of the Thirty-fourth Infantry were detached to form a flying column to rescue Lieutenant Gilmore and the American prisoners they were stripped of all superfluous clothing. Every blanket was left behind, officers and men faring the same. The officers carried a change of underclothing; the men leaving even this behind. The ones first taken with this fever were those who after a hard day's work in water, failed to dry themselves thoroughly before sleeping, and having no blanket became thoroughly chilled at night. The heat of the sun of the following day soon caused them to drop out of the column with a raging fever. Others predisposed to the fever were the few men who were continually on the lookout for alcoholic stimulants, which was in the form

of the deadly "vino." These soon succumbed. When we reached the mountains, and especially mountain valleys, the cool mountain breeze seemed to bring the fever with it, and those who had not indulged in excesses and with a fair covering at night even became subjects of this fever. During the march the command had practically the same rations throughout, which were generally rice, native sugar, native buffalo or vaca, and sometimes bacon. The best water available was used for drinking purposes, but in many instances this had to be taken from rice fields or muddy streams, and no time was available for boiling it. Very few mosquitos were found from Manila to Aparri, and as there wasn't a single mosquito bar along all fared alike. I don't consider them as a factor in any sense in the production of this fever.

In the towns and cities situated in valleys in the interior I found the fever prevalent among the native Filipinos. At Bangued especially was there a large number ill. While there a number of telegrams from General Tino to Aguinaldo fell into my hands. Leaves of absence were asked for a number of insurgent officers and many of their men who were suffering from "Calentura." Almost every family had at least one member sick with the disease. The Native Provincial President had 5 children and his wife sick at once. From many talks with the residents of that city, the fever always came concomitant with a breeze or wind from the mountains. "Malo viento" they called it.

In the cities along the coast San Fernando de Union was the first one we found with any quantity of it. At that place there were 124 soldiers of the Maccabebe scouts and a few Third Cavalrymen down with the fever. The unaccustomed exposure of the native scouts to a high altitude and the cold nights with no covering for them made them all easy victims. At Namapacan, a few miles further up the coast, about 35 more cases of calentura had developed among the Maccabebees who were accustomed to the warm climate and low altitude of the southern part of the island. Later on, at Vigon and Lavag, cases of calentura were seen, but in diminished numbers. Lavag being from the mountains a little distant, very few were discovered even in the months of January and February. The cases at San Fernando and Namapacan were seen the latter part of November, at Vigon and Bangued in December, while January and February were spent in Lavag. While at Lavag it was noticed that every 10 or 12 days a cool wind blew from the mountains to the sea. The cases of simple continued fever commenced at the beginning of this wind. The town of San Miguel is at the foot of the mountains, 4 miles from Lavag. The fever appears there among the natives at the same time that it appears at Lavag. More are attacked by it there. The town of Dingros is 12 miles from Lavag, and situated in the Dingros valley. The epidemics of calentura are quite severe there and correspond to the "bad wind" from the mountains. At all the three foregoing towns the water-supply is from a swift-flowing stream, the Lavag river, which is clear and flows over a gravelly bottom. Its source is in the neighboring mountain range. There are some mosquitos at each place, of a small variety, but I have never been able to trace any connection between the presence of mosquitos and the calentura. Unfortunately, our march was so rapid that it was impossible to carry along that indispensable aid in tropical diseases—the microscope, and it has not been my good fortune therefore to have its help.

I have tried to eliminate the mosquito-theory and also the water-theory as means of propagation of the germ that causes this fever. As the Maccabees suffered from it in changing from a low altitude, from a life on or near the water, to the high, dry, and cool mountains; and as there was no definite time for the recurrence of the fever, it does not have characteristics like malarial fever. The Spaniards here do not consider it as a malarial fever. One of them who had lived in the Province of Batanzas for twenty years told me that he suffered but once from it, and that was during the first year of his residence in this country. He attributed it to the effort of his system to become acclimatized. His wife, however, a Spanish mestizo, born in this country, suffers from the fever several times each year. Her attacks are usually concurrent with her monthly sickness. In the cases occurring among Americans I have noticed recurrences as many as nine times in six months in the same individual, but no definite interval elapsed. The cause was attributed to some excess in which the soldier had indulged. In one officer four days of fever from 104.6° to 106.2° occurred the last week in November, 1899. He was then marching north from San Fabian. The same kind of a fever recurred on March 27, 1900, at Lavag, and he had had perfect health during the intervening time. He spoke of the same "grippy" pains which he had before, and like many others remarked on the similarity to "la gripe" which he had experienced in America. But these recurrences at indefinite intervals seem to differentiate this class of fevers from the successive and periodical crops of the plasmodium malariae, as does the sudden rise of temperature, without the customary malarial chill preceding.

The differential diagnosis from dengue is difficult. The mode of onset is the same. The rheumatic-like pains in the limbs and the intense distress in the back accompanying the initial fever are identical. But the terminal fever and the ever-present eruption and desquamation of dengue are entirely absent. Variola, however, with its high initial fever and the exceedingly sharp pains in the lumbar region of the back, also is much like calentura. The attendant vomiting, severe headache, and great prostration of variola are the early differences. Several times have I seen one mistaken for the other. One of the mistakes was very vividly impressed on my mind. Private R., Company F, 34th U. S. V. Infantry, on the night of December 3, 1899, had severe pains in legs and back, temperature 106.2° . As this followed a hard march that day and I had several others with similar temperature and pains, the diagnosis of calentura was made. The next day occurred the battle of Tanguadin Pass, and all sick were left three miles in the rear. On the following day R., still having the same pains and from his own account a high fever, was picked up by General Young's wagon-train and carried to Vigan. At that place he was treated by two assistant surgeons of the navy at a temporary hospital. On December 6, the third day since I saw him, he walked into the hospital I had established at Vigan for the wounded of the Tanguadin and Vigan battles. At that time he was carrying his bedding and feeling first-rate. But there were about a dozen of the true vesicles of smallpox on his face. He was at once placed in an isolated building. The next day a case of smallpox developed in the wards which had been diagnosed by the surgeon in charge of the ward as "calentura." It is often impossible to dis-

tinguish between the two until a couple of days have passed.

Typhoid fever will not be diagnosed in a case of calentura, on account of the temperature-chart, absence of epistaxis in calentura, absence of abdominal pain and borborygmus, absence of the typhoid eruption.

The treatment among the natives is to wrap a cloth tightly around the head and lying down wear the fever out. I have never seen any benefit from this plan. However, it is universal among the Filipinos to tie tight bandages around the affected organ or where the pain is felt, no matter if it be an asthmatic chest or a pregnant uterus. The native physicians give an emetic and follow with large doses of quinin, a gram being the size of some of the doses given. They do not understand the Brand system of cold baths, nor do they fully comprehend the benefits of the coal-tar products. In the first case of calentura I tried quinin in small, and then large doses, but so far as I could determine no specific effect ensued; only the antipyretic action incident to large doses. I came to the conclusion then that the native physicians used quinin because of no better antipyretic available, and also from long-established usage. Quinin could be secured in most large towns, while other antipyretics were not to be had. In treating the Maccabees at San Fernando each one of the 124 were stripped and given a cool bath, followed by an antipyretic. When on the march a soldier would suddenly be taken ill with the calentura he was placed on the bottom of a caribou cart which was impressed into service at the nearest village. Fifteen to twenty grains of phenacetin or antipyrin were given him and a banana leaf put over him. In this fashion he would be pulled along in the rear of the column. If we had a little malted milk, it was given; if not, some rice and chicken soup. In two or three days he would be able to resume marching. The large doses seemed specific in action, as I rarely saw a recurrence. In the Abra valley, especially at the capital, Bangued, I used acetanilid and antipyrin with excellent success. About 20% of the population were sick with calentura during my stay there, and most of those brought to me were relieved by a simple purgative and one dose of an antipyretic. Cool baths would have been used also but for the fact that water was scarce and had to be carried two miles. However, after the fever was allayed the soreness in the loins and legs often persisted for several days. This was combated by a liniment of equal parts of kerosene, cocoanut oil, and vino, three ingredients to be had anywhere in Luzon, which was thoroughly rubbed into the affected parts.

Calentura is rarely fatal in this country. The short duration takes away the dread of it. Out of over 900 cases I have personally seen, only 3 were fatal. One of them was an old lady in her dotage, living in Bangued, in the province of Abra; her weakness was such that any disease would carry her off. The other two were little Maccabee scouts, too small to be soldiers, who had endured unnumbered hardships and exposures in the mountains near San Fernando de Union. They were brought down to the city too weak to eat their ration of rice, and having had no medical attendance, both suffered the typical symptoms of calentura, one dying just before our command entered the city, and one just afterward. In all these cases death seemed to be due as much to other causes as to the fever itself.

Finally, whether this fever will be designated as one of the obscure varieties of malarial fever, or will be

known as a distant relation of "influenza," which it simulates often in epidemic form, or whether it will continue to be one of the many unclassified fevers of the tropics with only a local appellation, time and the microscope will decide.

APPENDICITIS: PIN IN APPENDIX.—ABSCESS OF LIVER.—PURULENT PERITONITIS.—DEATH.

By E. H. TROWBRIDGE, A.B., M.D.,
of Worcester, Mass.

Surgeon to Worcester City Hospital.

A. P., aged 33, married, laborer, examined December 27, 1899. Family and personal history not important. Present illness dates back to December 10, 1899, when he came home from work complaining of chill accompanied with pains in all parts of the body. In the course of two or three days the pains ceased, and since then has had pain over the region of the stomach, and being unable to take a deep inspiration.

Physical Examination.—Pulse, 112; temperature, 100.2°; respiration, 25. In the lungs there were audible a few diffused, squeaky sounds. The heart was negative. The liver was enlarged upward. On the right side, just below the margin of the costal cartilages, and over the epigastrium, considerable tenderness on moderate pressure was elicited. Below the costal margin in the right mammary line there is a small area of swelling and increased tenderness, from 1½ to 2 inches in diameter. The abdominal muscles were very rigid, so that deep palpation was unsatisfactory. The urine, negative. From the date of entrance to the hospital (December 27) to the 31st, he had at various times attacks of severe abdominal pain, accompanied by green vomit. The abdomen became more distended and more tender. On December 31, in the morning, he had an attack of severe pain on the right side, lower down in abdomen than on previous days. The abdomen was universally sensitive and greatly distended. He had two attacks of vomiting, the vomit being green in color. The perspiration for two days had been profuse.

During the morning visit on December 31, 1899, I was asked to see the patient and the examination revealed the following: The patient has a pasty color and an anxious look. Pupils dilated; he sweats profusely; the tongue is thick and covered with white coat. He is nauseated and vomits a dark, green fluid. The chest is negative. The abdomen is uniformly distended and extremely rigid; a *boggy feel*, though nothing definite can be felt; he lies with limbs drawn up, and has slight tremor. Leukocytosis, 25,000. The abdomen was barrel-shaped.

At the time of examination it was evident that there was pus in the abdominal cavity, and the writer believed then that the appendix was the primary cause of the condition of the patient. An exploratory incision was advised and the patient prepared for operation, which was done on the afternoon of the 31st. An incision, 4 inches in length, was made in the right linea semilunaris, commencing just below the costal margin. The abdominal cavity contained a large

amount of seropurulent fluid; the bowels in the immediate vicinity were covered with pyogenic membrane—evidence of purulent peritonitis. The liver presented a dark and mottled appearance, but no evidence of a pus-cavity could be located by the hand, which was passed up and over the left lobe and the right lobe; the fact that the surface of both lobes was uniform in smoothness to the touch was due, I believe, to the immense pressure and distention.

On enlarging the incision downward toward the appendix, the bowels were seen covered by a purulent exudate, and

Appendix with pin in place, the head of pin in the distal end, and the remainder of appendix slit open.

the abdominal cavity filled with the seropurulent fluid as was first observed. The appendix was covered with this purulent exudate. On examining the appendix something hard could be felt in it and at its distal extremity a nodule could be seized by the thumb and finger. The appendix was drawn out of the wound and amputated; the stump was inverted and sutured. The abdominal cavity and the pelvis, in which there was a large amount of this seropurulent fluid, were thoroughly irrigated with normal salt-solution.

While this was being done, the appendix was slit open, and from it was removed a small shawl pin an inch and one-half in length. The base of the appendix was immensely thickened,—nature's method to protect the part from the point of the pin and prevent dangerous consequences. After irrigation the incision was closed, as in emergency cases, with silk sutures which were passed through the abdominal wall. A small opening was left through which passed the strip of gauze packing. The patient's condition at the end of the operation was fair; it was necessary to administer stimulants during the operation. The pulse was 140 and the temperature 102.6°.

From this time on until January 3 the vomiting persisted, the peritonitis continued and patient died at about 4.15 of the afternoon of that day.

On the patient's being questioned as to his swallowing the pin, he stated that he had no recollection at all of swallowing it.

There were present at the operation, Dr. G. H. Tripp, who sent the patient into the hospital, and Dr. Wesley Davis, of the medical hospital staff, who had charge of the patient up to the time of operation.

At the autopsy on the 4th, Dr. F. H. Baker, pathologist to the Worcester City Hospital, found three abscesses in the liver, one in the left lobe which had ruptured and two in the right lobe.

¹ Reported February 14, 1900, at meeting of the Worcester District Medical Society.

Home Rule in Medical Ethics.—When gentlemen join their efforts for carrying out a work which they have at heart they do not inquire as to the private opinions of the members on subjects which do not concern the undertaking in hand. When scientific medical men form an organization for prosecuting scientific research and for advancing medical art and education, why should they look into each other's personal opinions upon matters which do not directly relate to scientific things, and over which men will eternally differ? Home rule is of the essence of republicanism or democracy, and surely of that of the American type. Upon questions of medical ethics practitioners will forever differ when it is attempted to reduce these principles to definite hard and fast binding rules. Why, therefore, should not these things be left to the local organizations, who when they elect delegates to the national societies (the American Medical Association and others) assert that these are duly authorized to represent them in scientific things, and that the home organization is the best judge of the delegates' ethical qualifications? Let us unite the American medical profession, and, as a prerequisite thereto, let us have home-rule in medical ethics.

Scientific Milk-Supply.—The person who should secure for a city a supply of pure and rich milk would be more worthy of a place in a praiseworthy "Hall of Fame" than any so far included in the proposed New York list. There is, of course, no danger that the judges would include him in that farcical list, and it is more certain that he would not wish to be in it. We call especial attention to the report, in our forelying issue, of the Philadelphia Pediatric Society. In it one will find the indication of a spirit which hardly exists elsewhere in the world than among scientific medical men. We mean the application of scientific principles to the prevention of human suffering by the very men whose livelihood at present comes from that suffering. Despite the popular ingratitude which turns to every crazy 'pathy and every idiotic sort of quackery which ingenuity can devise, despite the hatred of the profession by the rabid antis of a hundred kinds, we everywhere find the hated men straining to render their own calling useless, and for the good of the ingrates and haters. The illustrative work of this society to which we refer has a distinctive and unique value. Not only is it

doing the extremely important negative duty of freeing milk from noxious ingredients, but it is positively seeking to increase the nutritional qualities of milk so that this shall not only not harm, but shall have the greatest nourishing value. Such a work requires, as those know who have looked into the matter, more than a revolution in the occupations of farming, dairying, and milk-handling; it demands long education and persistently upheld consciences of every man engaged in these industries. It seems strange that while men give millions to alleviate the results of evil, or waste millions in self-flattery, few or none care about preventing the causes that bring about the bad results. We still await with ever fresh disappointment the coming of rich men who will endow organizations of preventive medicine. The death-rate and the sufferings, and the expenses of American life can now be reduced by one-half whenever a few rich men agree to utilize the good will and the good science of our profession in that work. If that benevolent man, Mr. Andrew Carnegie, would give us one-tenth of the money he proposes to give away each year, we would undertake to do ten times the good with it that he will effect with his nine-tenths.

Unchristian Unscience, not being the product of reason or of morality, is not, of course, affected, so far as concerns its adherents, by logic or by immorality. If it can withstand the riddling given by Purrington, and the laughter of Mark Twain, it may yet live awhile. But this is on the condition that the grinning death's-head of financial trickery do not bring it up standing. *Harper's Weekly* proves what has long been suspected, that the money of the faithful is cunningly used to bolster their faith, and bring more money, by the old arts of the advertiser and of reading notices. It says:

The present paragrapher noticed with interest the other day in an important newspaper published in one of the larger cities of New York State an account in detail, half a column long, of the recent appearance of Mrs. Eddy, the Christian Science seeress, at the State fair in Concord, N. H. The piece had a prominent place and an extended heading in big type, such as is given to important telegraphic news, but from peculiarities of type and other marks it was suspected that it was a paid advertisement. So it was, as was ascertained by inquiry of the manager of the newspaper. This is the first instance the present writer has noticed of the employment by Eddyites of patent-medicine methods. It is a natural development. There is a great deal of money now invested in Eddyism, and a good many persons get their living by it. No doubt skilful advertisement of its founder's triumphs is worth to some one whatever it costs.

Church Dispensaries.—The Rev. David H. Greer, a distinguished clergyman of New York, is much interested in a fine new dispensary which his church is about to build as an adjunct to its parish work. This fine dispensary is to cost \$200,000. The work to be done in it will, of course, be charity work, and will be done largely by and at the expense of the medical profession. Rev. Dr. Greer, whose attention has been called to the abuse of this kind of charity, has written a letter in which he shows that he is entirely satisfied with this scheme for levying upon the medical profession for church charities. He thinks that there has been a great deal of "cheap and superficial statement" about persons going to dispensaries who are able to pay. Such cases, he is quite sure, are exceptional. Too many persons, he complains, look at the subject from the professional point of view, and not from the point of view of the general public (and of Rev. Dr. Greer). The general public and Rev. Dr. Greer believe, of course, that the best kind of medical work is charity work. Rev. Dr. Greer says magnanimously that if he were holding a brief for "poor and incompetent physicians" he might have something to say against church dispensaries, but as the brief he holds is for the "mass of the people" he is strongly in favor of exacting tribute from the medical profession, and he thus implies that the poor and incompetent physicians are none of his concern. We would simply inquire of Rev. Dr. Greer where he obtained his brief for the mass of the people, and by what authority he speaks for any one outside of his own parish? Rev. Dr. Greer reminds us of the Englishman who proclaimed that he was for the Empire and Little Pedlington. In this whole matter it is plain enough to be seen that the easiest kind of charity is that which one man does at the expense of another.

Opsomania.—A new disease is always a thing to be welcomed, for it adds variety to life and, sometimes, to death. But when, with the advent of a new disease, there comes also the announcement of a sure cure for it, the event has a double interest for physicians. Opsomania is the latest new disease, and hypnotism is its remedy. Like dipsomania and pyromania this new creation in the world of pathology is a process of degeneration, but whether or not it has yet received the approval of Nordau we cannot say. We herald opsomania as a new disease because its discovery has just been announced by a very respectable newspaper, but we regret to say that when we come to look the subject up, we find that the newspaper, as is not unusual, is away behind the times in pathology. Opsomania has had a place in the medical dictionaries for some years, and was, if we mistake not, announced by the London *Lancet* as long ago as 1892. It is characterized by an uncontrollable desire for sweet and dainty food. As such it would not be an alarming disorder, if it were not that it attacks young women and demands for its

relief a supply of confectionery at the hands of young men. It therefore urgently demands a remedy, and to meet this demand a recent work on hypnotism gravely suggests that a cure for it is found in hypnosis. We publish these facts for what they are worth, but for ourselves we doubt whether there is any cure for this disorder in young women. It is worth while noting, however, that the science of hypnotism seems to be itself degenerating to the level of trivialities.

Dangers to Health from High Buildings.—The *American Architect* evidently dislikes "sky-scrapers" for esthetic reasons, but in order to make out the whole case against them, it does not confine its criticism to esthetics, but goes into the subject also of hygiene. These huge structures, according to the *Architect*, deprive adjacent streets of light and air; they promote a congestion of both foot and wheel traffic in their neighborhood; they complicate the problem of protection from fire; they overtax the capacity of the sewers and water mains that serve them, and they increase the dangers of elevator travel. Moreover, the *Architect* hints darkly that these monstrous buildings cause a variety of new diseases hitherto "unknown to the human frame"—(and likewise, we suppose, to the doctors). That tall building are hotbeds of new diseases, is a novel idea to us, and we call upon the *Architect* to hasten and inform an anxious medical profession what the symptoms of these rare and curious affections may be. Our contemporary says that it has even seen mention of an alarming mortality among elevator conductors, forced to travel at speed through these drafty vertical tunnels day after day under varying conditions of temperature. The worst indictment, however, is brought by Professor Hyatt, of St. Louis, who claims that these monstrous structures perceptibly increase the temperature in a city. But this, while an evil in summer, would not be a disadvantage in winter; in other words, the evil is balanced by the good. We think, moreover, that such effects must be but slight, and only felt in the immediate vicinity. On the other hand, there are probably many hygienic advantages in this very respect in tall buildings, and these the *Architect* should acknowledge. These building supply offices and workshops that are splendidly lighted and ventilated, and high above the noise, and dust, and flies, and atmosphere of the streets. Such offices are in marked contrast with the old dingy, deeply-buried dens so often found in old-fashioned buildings. In a hot summer there is some solace in being 75 or 100 feet above the street. From the esthetic standpoint we agree with the *Architect*, but from the hygienic point of view we must dissent on some accounts at least.

Raw Food for Diet.—From Chicago we learn that the latest advance in dietetics is the use of raw food. If reports are true, some of the Chicagoans are eating raw

flesh and uncooked vegetables. The great apostle of this movement is Prof. Tyler, of Indianapolis, whose name sounds rather familiar to us as an advanced thinker of the day. The philosophy of the raw food cult is easy to understand. Fire, it is claimed, destroys all that is life-giving and healthful in food. As man is the most intelligent of all animals he ought, according to Prof. Tyler, to live longer than any other animal. The logic of this statement is not quite apparent, but the subject is further illustrated by examples from the lower animals. For instance, a gosling becomes a goose in one year, and lives to be twenty years old; a swan gets grown in two or three years and may reach the century mark; a horse requires five years for his development and lives to be twenty or even thirty years old; but poor man requires, according to Prof. Tyler (but not in fact), twenty-five years to develop, and lives on an average to be only thirty-four. The reason for all this is found in the fact that man, for some unknown reason, eats dead cells that have been cooked and thus rendered unfit for nutrition. Cooking expels all the acids and gases, so necessary for the preservation of health, and nothing is left but a supply of ash, lime, and other unsuitable substances.

We do not quite see the accuracy or logic of all these statements, and if they are propounded seriously they are merely evidences of the loose thinking that is a prevalent characteristic of the times. The subject of how and why and when man became a cooking animal, is a curious and interesting one in anthropology, but it leads the inquirer far back into the dim regions of remote antiquity. We doubt not there were good and natural reasons for it, and we advise our readers to cling to this ancient usage, and leave it to our friends in Chicago to eat raw flesh and uncooked vegetables. Tapeworm and other parasites, together with pathogenic bacteria, will do less harm when killed by cooking than when eaten alive with raw food.

Increased Prevalence of Insanity.—In his address on the Prevention of Insanity, delivered as President of the Section on Psychology, at the recent meeting of the British Medical Association, Dr. R. Percy Smith pointed out that the total number of patients in England and Wales under the cognizance of the Commissioners in Lunacy on January 1, 1899, was 105,086, or 3,114 more than in January 1, 1898. In addition to this absolute increase there was also an increase in the ratio of the insane to the general population, the proportion being as 1 to 306 in January 1, 1899, as compared with 1 to 308 on January 1, 1898 and in 1 to 337 in January 1, 1899. In commenting on this paper the *Lancet* points out that the ratios in Scotland have been as follows: in 1881, 1 to 374, in 1891, 1 to 320, in 1899, 1 to 278; while in Ireland the figures were for 1891, 1 to 328, for 1899, 1 to 222. Probably no single factor is responsible for the increased prevalence of insanity that the

figures cited indicate; but there is scarcely room for doubt that the most potent influence is the modern method of living, with its ceaseless activity, its strains and competitions, its overwork and underrest, and there can be no hope for relief until the higher civilization comes when each will be more thoroughly solicitous for the wellbeing of his fellows and the half of life will not be wasted in the struggle for maintaining the other half. Heredity is the most potent etiologic factor in the development of insanity, and its influence can be removed only by educating the people to a knowledge thereof and the adoption by them of the only practical restrictive measure, namely, abstinence from marriage and procreation on the part of those who have been insane or are descended from insane progenitors. Alcoholism and syphilis are next in importance as causes of insanity and their influence too is to be removed by an enlightened self-repression, together with rational restrictive legislation.

The Cost of Crime.—Mr. Eugene Smith, a well-known writer in sociology, recently read a paper before the Prison Congress at Cleveland, Ohio, in which he made an attempt to estimate in dollars and cents the cost of crime. As Mr. Smith pointed out, it would be a great mistake merely to take the cost of maintaining the prisons, the police, and the criminal courts as the measure of this cost. The problem is much more complicated, for this charge affects almost all items of public expenditure, directly or indirectly. For instance, the expenses of the executive and legislative, as well as judicial branches of government, are chargeable in a certain proportion against crime. The militia also of a State is supported in part as a guard against riot and disorder. Finally, the cost of maintaining public charities is largely to be charged against law-breakers. The enormous sums spent in this way are, according to Mr. Smith, at least double what they would be if there were no such thing as crime.

According to the *Evening Post*, the author arrived at his estimates by analyzing the statistics of certain large American cities. In New York the outlays, in 1899, which might be charged wholly to crime, were \$12,988,804. These outlays were for the Department of Correction, District Attorney's Office, Police, and the Courts. To these are to be added a large proportion of the expenses of the Sheriff's office—at least \$7,789,259—making a total of more than \$20,000,000. As the total tax-list of the city is \$90,000,000, it thus appears that crime entails almost one-fourth of this burden upon the public. From this and similar analyses in New York and other cities, Mr. Smith estimates that the annual cost of crime for each citizen is \$6 in New York, \$5 in San Francisco, and in some other cities named from \$3 to \$3.50.

In the whole United States a total annual expenditure of \$200,000,000 is chargeable to crime. Of this

sum, about one-half is city taxation, and about one-quarter is town and county, and State and Federal, taxation respectively.

If now to all this vast sum is added the earning capacity of criminals, which is not realized, and which Mr. Smith estimates at about \$400,000,000, we have the enormous total cost of crime in the United States as about \$600,000,000. These figures give food for reflection, but the remedy, unhappily, in the present state of society, is not in sight.

Increased Frequency of Suicide.—The question as to the justifiability of suicide has at all times been a debatable one, and the answer will probably never be unanimous in either the negative or the affirmative. Apart from the presence of actual mental disease, any opinion on this subject must be based on ethical grounds, and it will necessarily vary, therefore, in accordance with the habits of thought, the social environment, and the mode of life of the individual and the community in which he lives. The time is past when suicide can be considered exclusively an insane act. While it may at times seem unjustifiable or irrational, it may, nevertheless, be the outcome of calm, deliberate, logical reasoning. The act, however is one that cannot be sanctioned by any authority, as it does not make for the common good, and although the individual is not responsible for his introduction into existence, yet having become a part of it, he has acquired certain obligations which he cannot with right and justice shirk. His life, his potentiality, and his other attributes are not really his to dispose of as he would; but they belong to the world, of which he is only an atom. In some communities suicide is by law declared a crime, the penalty for which must be borne by the victim's estate; in others, punishment is prescribed for unsuccessful attempts. In concluding an interesting account of the light in which suicide has at different times and by different persons been viewed, Styles (*American Journal of Insanity*, July, 1900, p. 97) cites statistics showing the extent to which the act has increased in frequency. Thus, there were in France from 1841 to 1845, among every 100,000 of the population, 9 suicides; from 1846 to 1850, 10; from 1861 to 1870, 13; from 1871 to 1875, 15; from 1876 to 1880, 17; for 1890, 21; for 1893, 22; and for 1894, 26. Between the years 1826 and 1890 the number of suicides has increased in Belgium 72%, in Prussia 411%, in Austria 238%, in France 318%, in Saxony 212%, in Sweden 72%, and in Denmark 35%. Norway constitutes an exception to the general rule, the proportion of suicides per million having declined steadily from 108, in the period from 1831 to 1835, to 67 in that from 1881 to 1890. It is especially interesting to note that this reduction corresponds with a decrease in the consumption of alcohol. In Great Britain, conversely, it has been found that the increase in suicide and in attempts

at suicide is concurrent with an increase in alcoholism. It has been observed, further, that suicide is less prevalent in Roman Catholic countries than in others, the proportion per million being 68, as compared with 100 in Protestant countries. It is also less common among the married than among the unmarried.

Tuberculosis of the Skin.—An interesting discussion on the subject of tuberculosis of the skin took place recently at the Cincinnati Academy of Medicine. Dr. Ravogli considered the clinical phases of the disease, and adhered closely to the classification of French writers, particularly Leloir, who makes the following divisions:

A. True lupus exedens and nonexedens.

B. Atypical varieties of lupus: (1) Lupus vulgaris colloides; (2) lupus vulgaris myxematosus; (3) lupus vulgaris sclerosus; (4) lupus vulgaris erythematoides.

C. Scrofulotuberculosis: (1) Dermic gummata; (2) hypodermic gummata.

D. Ulcerous tuberculosis: (1) Primary ulcerations; (2) secondary ulcerations.

E. Mixed skin tuberculosis from two or more varieties.

On the much-discussed subject of lupus erythematosus, Ravogli pronounces himself in favor of the tuberculous nature of the affection. The eruption may not be due to the tubercle-bacilli itself, but to its toxin.

The pathology of tuberculosis of the skin formed the theme of a paper by Dr. Heidingsfeld, who divided the lesions into (1) the typical or primary, called lupus, or tuberculosis vulgaris cutis; and (2) the atypical, or secondary, commonly called scrofuloderma. The first are caused by the direct infection of the skin by the tubercle-bacillus from without; in the other the skin becomes secondarily involved by the direct extension of a tuberculous process in an adjacent tissue, most frequently by the breaking down of an underlying tuberculous gland. The second form is the more common, at least in this country.

In discussing the treatment of tuberculosis of the skin, Dr. Drury dwelled first upon prophylaxis, and then cited the various active measures employed to arrest and cure the disease—caustics which are not much in vogue at the present day, galvanocautery and excision, which are only applicable to small lesions; cureting, which may be useful in superficial lesions, and may be followed by the application of caustic potash or a pyrogallie acid ointment; and linear scarification, which has the disadvantage of requiring a long time before it yields results. No reference was made to phototherapy, a treatment that seems to be full of promise.

Much has been said about the extravagances of dermatologic nomenclature, and in no subject is this more patent than in that of tuberculosis of the skin. If dermatology could only divest itself of its cumbersome and largely antiquated phraseology, and if it would

seek to find, in addition to the Latin terms, equivalent expressions in the vernacular, it would be far more interesting and intelligible to the general practitioner, and discussions like those in the Cincinnati Academy of Medicine would be more frequent, to the common advantage of all branches of medicine.

Correspondence.

AN EARLY SIGN OF TYPHOID FEVER.

By H. H. VINKE, M.D.,
of St. Charles, Mo.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

IN typhoid fever I have found the presence of a few scattered sudamina, or clusters of sudamina, over the inguinal regions, near the anterior superior spinous processes of the ilia, an early and fairly constant symptom. These sudamina appear at a very early stage of the disease, several days before the rose-spots make their appearance. At a later stage of typhoid fever, when the fever begins to subside and the patient is perspiring more or less freely, sudaminal and miliary eruptions, at times over the entire body, are frequently found.

But these eruptions are not characteristic of typhoid fever, but are found in all diseases that are accompanied by profuse sweating, and at times in healthy individuals who perspire freely. The eruption I have described, however, I have found in cases in which there was scarcely any perceptible perspiration, and I would like to know whether their presence under these circumstances possesses any diagnostic value.

SPECIMENS OF MALIGNANT GROWTHS DESIRED.

By CHARLES E. SIMON, M.D.,
of Baltimore, Md.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

LAST March I directed an appeal to the American medical profession at large, through the columns of your esteemed JOURNAL, requesting that specimens of malignant growths be sent me for the purpose of a chemical investigation. As a result, I am indebted to you for a number of valuable preparations. The amount of material, however, which I have so far been able to obtain is not sufficient for the work intended, and I therefore take the liberty of asking your aid, once more, in this direction. Specimens, to be of value, should be cut in small pieces and placed in chloroform-water (containing about a teaspoonful to the quart) as soon as possible after removal at operation or postmortem examination. They may then be shipped to me at my expense. Records will be kept of every specimen, and due credit given at the proper place.

Trusting that this appeal will lead to the desired end, accept my thanks for your courtesy.

1802 Madison Avenue.

HAT PIN IN THE URETHRA.

By CHAS. M. ELLIS, M.D.,
of Elkton, Md.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THREE cases of this accident have been reported. I add another, making the fourth. A man, 70 years of age, came to

my office early on an October morning in 1893, from Herford County, Md. He had enlarged prostate. He declared that he had, on several previous occasions, used a hat pin with which to relieve himself when he had trouble in passing his water, but that on the previous evening the instrument had escaped his grasp, and the head had passed into the bladder. The point of the pin was immediately located in the urethra, behind the scrotal attachment. Fixing the point, I caused it to penetrate the penal urethra and the overlying skin. This I seized and drew out until the head engaged in the urethra. Depressing the point, the head was made to travel the urethra reversely, and was taken from the meatus in less time than it requires to describe the operation. The pin was 8 inches long, and the head $\frac{3}{4}$ of an inch in diameter. Incision of the urethra, which was practised, I believe, in all the other cases reported, was entirely unnecessary in my case, and in all probability equally unnecessary in the others. Relief was immediate, and no after-treatment of the minute puncture was required.

DESIGNATION OF THE OPERATION OF ROUND LIGAMENT VENTROSUSPENSION OF THE UTERUS.

By CARL BECK, M.D.,
of New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

YOUR issue of September 29 publishes a description of my method of operation on "Round ligament ventrosuspension of the uterus" (ligamentopaxis), by Dr. D. Tod Gilliam, of Columbus, Ohio, which gives every detail of the various steps of the operation, but does not mention my name. My method was first published and illustrated in the *Centralblatt für Chirurgie*, August 21, 1897. It was also reported by Dr. C. A. von Ramdohr before the New York Obstetrical Society in the same year, and was the subject of a graduation thesis at the University of Paris, under the auspices of Poirier, Berger, Guyon, and Albarran. Garrigues' "Diseases of Women" also contains it, and the *American Journal of Obstetrics and Diseases of Women and Children*, vol. xlii, No. 3, 1900, gives a description of the original operation and some of its modifications.

I must assume that all this was entirely unknown to Dr. Gilliam, and that on being informed of the facts, he will correct the omission.

POISONING BY CODEIN.

By M. J. KONIKOW, M.D.,
of Boston, Mass.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

IN looking up the literature on poisoning by codein I did not find any case reported that would be similar to the following, which was observed by me lately. On April 23, in the morning, I was called to see a little patient—a strong, fairly-developed nursing boy, about a year old. An examination revealing nothing except high temperature, caused probably by cutting of the upper incisors, I left a prescription calling for powders of phenacetine in half-grain doses. About 10 P.M. the same day, the druggist informed me through the telephone that a grave mistake had occurred; instead of delivering the powders intended for my patient, he delivered powders intended for another adult patient, containing each 15 grains of bismuth and $\frac{1}{4}$ of a grain of codein. On arriving at the house I found the child asleep. It

had been made to take the enormous powder in toto, at about 8 P.M. The pulse was about 110, but otherwise normal. The pupils were normal, reacting to light. There was no nausea and no depressing symptoms. I ordered the white of an egg, followed by repeated doses of ipecac sirup, with the usual result. I left instructions to keep the child awake for a few hours. I saw it in about an hour and a half afterward. It was sleeping, though easily to be aroused; there was normal breathing, and the pupils were more or less contracted. The next day the child was normal except as to the stools, which, as I expected, were black.

Most remarkable in this case was the absence of any symptoms of poisoning in spite of a relatively large dose of codein. There are cases on record in which smaller doses in proportion have produced quite severe symptoms. C. Mettenheimer¹ reports a case where severe vomiting, colics, retention of urine, profound sleep and myosis, followed in an adult person a codein dose of 2 grains. Dr. Reamy² has also observed some disagreeable symptoms in an adult patient after a dose of one grain of codein. According to Young's formula, taking as the maximum dose of codein for an adult two grains, we would have the maximum dose for a child one year old, $\frac{2}{3}$ of a grain. The only explanation I can have for the absence of unfavorable symptoms in this case, is the great amount of bismuth subnitrate (15 grains) which probably held the codein in suspension, preventing its absorption.

A CASE OF BROMATOTOXISMUS WITH ABSENCE OF NAUSEA, VOMITING, AND PURGING.

By A. F. KINGSLEY, M.D.,
of Centerville, Mich.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE patient was F. S. C., male, aged 40 years. On the morning of August 19, together with others of his family he partook freely of frozen strawberry sherbet which had been made the previous afternoon. Some hours later—about 11 30 A.M.—the frozen sherbet being entirely gone, and a little of the thawed product remaining, he drank this—about four fluid-ounces. In about an hour he was taken with severe griping pains in the suprapubic region, radiating upward in the abdomen, being most intense on the left side. He felt a desire to go to stool, which was gratified, the movement being about normal, except for the griping pain which increased. Patient was slightly nauseated, but did not vomit. Arriving about 15 minutes after the beginning of the attack, I found the patient occupying the dorsal position with the thighs flexed, with evidences of great pain. Upon ascertaining what he had eaten, I administered hypodermically atropin sulfate, grain $\frac{1}{6}$, and a little later, by the same method, apomorphin hydrochlorate, grain $\frac{1}{16}$. This promptly induced vomiting, so that the stomach was very thoroughly emptied. The vomitus was of a dark brownish color, containing bits of undigested apple which he had recently eaten, together with some strawberry seeds from the sherbet; it emitted a slightly disagreeable odor.

The abdomen was now so tender that the weight of the hot-water bag could not be endured, and hot flannels were applied and frequently changed. The pain continued and the man was unconscious at short intervals; a few tonic convulsions developed. I now gave atropin sulfate, grain $\frac{1}{16}$, with morphin sulfate, grain $\frac{1}{4}$, hypodermically, and about 3 hours from the beginning of the attack the pain gradually lessened

and in a half hour more the patient was very comfortable. I left some belladonna to be given that night, and returning in the morning, found the patient had rested quite well during the night and was then very comfortable except somewhat sore and quite exhausted. He continued to recover rapidly and was soon about his usual duties.

There was no history of renal calculi nor did anything appear after the attack, such as the passing of a calculus, or of bloody urine, which would point to such a diagnosis. In fact there was no history of kidney trouble, and Dietl's crisis was out of the question. My patient has no hernia, and intestinal obstruction is not to be considered, for patient's bowels were regular before the attack and have continued so since.

About 3 fluidrams of the thawed sherbet remained, and next day I fed this to a kitten. About 30 minutes after eating it, the kitten was taken very ill, and appeared to suffer from abdominal distress, but after about 3 hours recovered, without, however, any vomiting or purging.

I think this case interesting, inasmuch as it was undoubtedly one of bromatotoxismus, but with pain as the chief symptom, while nausea, vomiting, and purging, which are usually given as cardinal symptoms, were absent.

PROGRESS OF BLOOD-EXAMINATIONS.

By ROBERT L. WATKINS, M.D.,
of New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

WE like occasionally to take a retrospective view of blood-examination for disease. Thirteen years ago the disease known as leukemia was occasionally examined for by the instructor, or, more commonly, the professor, because others did not know how; it was so uncommon. This disease was discovered in 1846 by Virchow and is generally fatal. About that time, the spirochetæ of Obermeier, a parasite in relapsing fever, was known but was seldom looked for. Examinations by the profession were made only casually, and then more for curiosity than any other reason. Hanoque, of Paris, in 1892, was experimenting with his test for the coloring-matter in the blood. This had been worked out by Gowers, Fleischl and others, but none of these examinations was taught in the institutions.

About this time the importance of the plasmodium of Laveran was beginning to dawn upon the profession. There was nothing written upon the blood either in book or pamphlet form, that I could find except that mentioned above, and some matter, years old, which was considered by the profession as obsolete. Ehrlich was working on a certain method of staining the blood cells, and thus differentiating, as he claimed, certain diseases. This he was teaching to his private students, I was told when in Germany. Today a modification of Ehrlich's method is taught in all our institutions, and used in all the hospitals, where they test for the different kinds of cells, and malaria in all its forms, and, as is well known, they also use a test for the hemoglobin.

Ten years ago I remember speaking about the microscopic fibrin in the blood-serum to a professor in one of our laboratories. He did not know what was meant, and even when a photograph of it was shown to him, he did not recognize it. This same professor at the recent meeting in Atlantic City acknowledged that he was wrong at that time, and asked to see more of the work. Another young professor, at this meeting in June, said: "Oh, yes, there is fibrin in the blood, but it's in all blood, and is not pathologic."

When men will acknowledge progress in others and mis-

¹ *Memorabilien*, 1891-2, N. S., xi, 136.

² *Cincinnati Lancet and Clinic*, 1879, N. S., ii, 511.

mistakes of their own, it shows that the world is advancing. We hope before long that the pathologic importance of the several varieties of fibrin will be generally recognized for it; for we say here that in some diseases the blood contains very little microscopic fibrin, while in others it is abundant and of different varieties.

In a recent number of the *Journal of the American Medical Association*, Dr. Fussell has an excellent article on the "Examination of Blood," in which he says: "By the use of a microscope and a slide of fresh blood, one may observe: First, whether the leukocytes are largely increased in number; second, whether the red cells form properly in rouleaux." This examination of fresh blood is important, and I am glad to note that he is examining fresh specimens, and not old, even by one minute.

In regard to the leukocytes, I would like to call attention to the simple way of telling the number; I presume the doctor uses the same method by his use of the term "largely increased." It is this: In healthy blood with a $\frac{1}{4}$ objective, there are visible on the average one or two leukocytes to every microscopic field. Anything more or less than this is abnormal. This is much easier to consider, and just as practical as the tedious method of counting with the Thoma-Zeiss apparatus. I also note in his Textbook, Osler uses the term 1 to 6 in comparing the white and red cells. I am glad to note that he also is using the method I have used so long, of simply counting without a counting apparatus. By using this method it only takes a few minutes to make a photograph, and thus have a definite record, for the photomicrograph you can examine any time and keep for future use.

Dr. Fussell mentions a case—Miss P.—in which endocarditis was present and the increase in white cells was marked, and he gives the actual counts. I remember a girl, 10 years old, who had a severe endocarditis, and the blood also showed this increase in leukocytes (see illustration), but I did

FIG. 1.—During the attack of endocarditis.

not, and never do, go to the trouble of counting the leukocytes. Make a photograph, and there you have them. This patient we mention is now 16 years old, is perfectly well and free from any perceptible cardiac lesion (see photograph taken lately). She has no increase in white cells now, they being perfectly normal. I would like to repeat that for practical purposes the counting of the white cells by the Thoma-Zeiss apparatus is merely a consumer of time, and that one's judgment, as pointed out above, is the only practical method.

Second. He says we should note "whether the red cells

form properly in rouleaux." Dr. Cabot also mentions this in his work, and I am glad to note that the profession is now recognizing this rouleaux arrangement in health. For it, as

FIG. 2.—After recovery.

as well as the even distribution of the red cells, is characteristic and important in fresh blood. Old blood is liable to be evenly distributed after only a few minutes' standing.

TREATMENT OF HEMORRHOIDS BY INJECTION OF CARBOLIC ACID.

By EUGENE F. HOYT, M.D.,
of New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I HAVE just read a most interesting and scholarly thesis in the current number of your JOURNAL, by Dr. J. W. J. Doyle, in which he discusses the Pathology and Treatment of Hemorrhoids. If a general criticism were allowed, I should say that in the article *theory* seems to override experience, and that the practical side of the question is lost sight of. Regret is expressed of the almost universal neglect of this subject by the profession, intimating that the widespread prevalence of irregular remedial agents must be due to want of success on the part of general practitioners. As a result, nearly all patients are fearful as to the outcome of surgical interference, and hence the great prevalence of rectal diseases today.

One of the most startling features of Dr. Doyle's paper takes the form of a sweeping assertion that seemingly brushes out of existence the method of management known as interstitial injections. So drastic are his words that every one must infer that in all cases treated by this method the attending physician is paid by the executor of the patient's will. Such is not the result of my experience in an exclusive practice of this specialty for 26 years, in which I have used this treatment many thousand times. With this experience I feel that a wholesale condemnation is hardly a fair presentation of the subject—it is a brief without any data. A proper experience can only be gained by treating something like 2,000 cases—as it requires something like this number of instances to make a medical proposition into a medical fact. One will then find himself equipped to deal with all such hemorrhoidal growths as are constituted by an anastomosis of the bloodvessels. Other forms are unadapted to this treatment. I inject into the hemorrhoids slowly and sparingly a 10% solution of carbolic acid, thereby neutralizing all nourishment of the tissue involved, so that this must promptly yield its hold upon existence, restoring the hemorrhoidal dominion to its original condition.

Society Report.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Twenty-sixth Annual Meeting.

THE twenty-sixth annual meeting of the Mississippi Valley Medical Association was held at Asheville, N. C., on the 8th, 10th, and 11th inst. Dr. M. H. Fletcher, as chairman of the Committee of Arrangements, called the meeting to order, after which the Rev. R. F. Campbell, offered up a prayer, and addresses of welcome were delivered by Mr. Theo. F. Davidson, on behalf of the city and State, and Dr. John Hey Williams, on behalf of the profession of Asheville. Mr. Davidson remarked that he did not like to greet the physicians present as healers, because this term had been rather brought into disrepute by those who professed to be able to heal without the aid of *materia medica*, and on the other hand there was a danger of their being confused with another body of men who were now being much spoken of—he referred to the Tammany healers. Passing on to speak of the locality in which the meeting was being held he said that the fine atmosphere of Asheville was the deadly enemy of the local doctors, who would literally starve to death if it were not for the patients sent them from other parts of the country. The president of the Association, Dr. Harold N. Moyer, of Chicago, acknowledged the cordiality of the welcomes, and then the official reports were read, all of them going to show that the affairs of the Association were in a highly satisfactory condition.

The President's Address.—DR. MOYER, in his presidential address, dealt with an apology for the American profession which had been delivered by one of its Nestors at the meeting in Paris of the International Medical Congress. He did not want to wash any professional dirty linen. If there was anything of that kind to be done, it could be best attended to in the local professional laundry. But there were some matters which had been referred to in the address referred to that were of the utmost importance alike to the profession and the public. In his apology the essayist went into particulars of a question of ethics which was twenty years old, but of which some scintillations appeared still to exist on the Atlantic coast. Most of them probably thought the subject long since dead and buried, but unfortunately it had not been embalmed, and now it had been resurrected with all its old malodorousness. He (Dr. Moyer) maintained that the American profession needed no apology, and as proof thereof he quoted from an editorial article in the *London Lancet*, in which it was pointed out that, allowance being made for the difficulties that had to be overcome in a new country, and particularly one where democratic principles prevailed, it was remarkable what American physicians and surgeons had achieved, and what had been and is being done to raise the standard of education among students of medicine. In the light of this quotation, it was evident that the American medical profession required no defence. All they needed to do was to apologize for the representative appointed to speak for them in Paris. One statement in the address referred to was that there were too many medical societies in America, the essayist referring to the fact that there were only two medical societies in the old Colonial days, in which he seemed to regret they are not still living. Here, again, he (Dr. Moyer) felt it necessary to express dissent. Not only did he think there are not too many medical societies; he maintained that even the most insignificant of them were helping to advance medical science, and that it was principally due to their united efforts that so much progress had been made, and that the profession occupied the position which had evoked the tribute of the *London Lancet*. In this country, it was to be remembered, they had almost no endowment of medical education or research. They had no Government subsidy, and no paid hospital staffs. But in spite of all this American physicians and surgeons were admitted to take high rank by reason of their achievements. The medical societies here had enabled the profession to do for itself what abroad was done for it by legislation and subsidy. Referring to the Mississippi Valley Medical Association, Dr. Moyer said some people thought there was no particular need for it, inasmuch as it did not represent any definite geographical

area and the State and National Associations might be supposed to meet all legitimate wants. The prosperity of the Mississippi Valley Association, however, was sufficient to show that it served a useful purpose; and it was noteworthy that its members were also active members of the National Association, of which the Mississippi Valley Association was a useful auxiliary instead of being in any sense a rival. Another matter of importance was the relation of law to the medical profession. A good deal of misapprehension existed as to the attitude of physicians and surgeons in relation to the movement for the passing of statutes for the regulation of medical practice. Legislation was required, not so much for the protection of the profession as for that of the public; and with the view of making the law operative against unqualified practitioners and quacks he suggested that, instead of attempting to define "practising medicine," they should leave it to the courts to say what came within that category. The law required that pilots of steamboats should possess certain qualifications as a guarantee that they could be trusted with the lives of the public; and that was all that medical men asked in regard to their own profession. Personally, they might prefer that there was no such thing as a Medical Practice Act; but laws of the kind were necessary for the protection of the public. Another charge of the essayist who had apologized for the profession at Paris was that in America they had too many medical journals, and that they did not all preserve the high standing that was desirable. The medical journals could no doubt be left to look after themselves; but those acquainted with the facts knew that the medical journals of America could compare favorably with those of Europe. There as here there were plenty of weak-kneed, advertising, nostrum-fostering journals, but the European journals of that class were unknown here, and it was mistakenly supposed as a consequence that all European medical journals were of the same high standard as the *Lancet* and the *British Medical Journal*. Dealing finally with the subject of specialism, Dr. Moyer showed that there was too much tendency on the part of beginners to aim at becoming specialists, whereas the only genuine specialties were those grounded on a good experience in the field of the general practitioner. Specialism in medicine was like matrimony. It should not be forced, but accepted only where it came naturally.

The reading of papers then proceeded, the first being one by DR. H. O. WALKER, of Detroit, Mich., on **Vaginal versus abdominal hysterectomy**. The question, he said, was largely one of working in a light or a dark passage. The conclusion at which he has arrived was that the abdominal route was the better of the two, and for the reason that, not only could the surgeon see more clearly what he was doing, but he obtained a better control of hemorrhages, and ran less risk of complications through the slipping of ligatures. In other words, the danger to the uterus was limited, and if any injury was done it could be easily repaired. The paper was favorably commented on by DR. E. W. LEE, of St. Louis, and others.

Cancer of the Uterus.—A paper on this disease and its treatment was read by DR. R. S. SUTTON, of Pittsburg, Pa. Cancer operations, he contended, should be recommended, not as curative but as palliative, and in that respect useful. Total vaginal extirpation of the uterus at or after time of climacteric, he said, should find a place as prophylactic treatment against cancerous disease. After reviewing the anatomy, pathology, diagnosis, and present method of treatment, the author said that treatment for existing cancer of the uterus had probably reached its complete evolution; but in view of the ultimate results of this treatment, which he heartily endorsed because there was no other known treatment to take its place, he asked, *cui bono?* Proceeding to discuss the question of prophylaxis, he stated that the average age of the patients he had operated upon was 43 years and a fraction, and claimed that if these patients had all been subjected to total vaginal extirpation at the average age of 40, all of them would have escaped cancer of the uterus. According to statistics he had prepared, only 4% of them would have died, whereas nearly 100% did die within a period of 2 or 3 years after operations for cancer. He urged greater attention to the early repair of lacerations of the cervix, together with a more painstaking observation and consideration by physicians at large of the train of symptoms which preceded and led up to the development of can-

cer of the uterus. Radical surgical treatment should be resorted to in all such cases; but above all if they were to reduce the number of cases of uterine cancer, and consequent mortality, steps must be taken to forestall the disease.

Tracheloplasty.—DR. H. P. NEWMAN, of Chicago, read a paper on this subject, in which he called attention to the need of recognizing the normal and pathologic significance of the cervix uteri, the importance of its function, and the improvement which had been introduced in the technic of the surgical reparation of this organ.

Postoperative internal hemorrhage was the subject of a paper by DR. A. H. CORDIER, of Kansas City, Mo. He showed that in diagnosing postoperative hemorrhage a review of the operative history should be gone over carefully. Symptoms of shock and hemorrhage were very similar, but in suspected cases a single stitch cut in a closed wound would tell the difference. In all cases when a hemorrhage was feared, a tube should be introduced. The surgery must be quick and decisive in postoperative procedures, and large quantities of normal saline solution would save many lives.

A case of **Intermittent hydrops of the knee** was described by DR. GEORGE W. CALE, of Springfield, Mo., the patient being a lady of 40 years of age who had recurrences of the disease at intervals from 1 to 6 months during the last 5 years.

Ventral Hernia Following Laparotomy.—In this paper DR. B. BRINDLEY EADS, of Chicago, emphasized the importance of this sequel of abdominal operations, discussing the principles involved in the choice of incision, the making and closing of the incision, and the way to cure ventral hernia.

DR. E. H. RICHARDSON, of Atlanta, Ga., reported a case showing perfect recovery following **Gangrene of the scrotum and penis**. The initial lesion was an abrasion of the skin near the os pubis with probable infection from the erysipelas cocci at this point, and later a mixed infection from the streptococcus of gangrene, terminating in the destruction of the gangrenous portion of the entire integument of the penis and of three fourths of the scrotum. Plastic operation was adopted with the effect of preserving the integrity of the penis and testes.

A paper on **Middle-ear disease in its relationship to the cranial cavity** was contributed by DR. ORTO J. STEIN, of Chicago, stereopticon demonstrations being given by an assistant. The object of the author was to show the necessity of recognizing the importance of possible intracranial complications in every case of middle-ear disease.

SECOND DAY'S PROCEEDINGS.

The proceedings on the second day commenced with an **Address in medicine** by DR. I. N. LOVE, formerly of St. Louis, now of New York, who chose as his subject **Nutrition and stimulation**. The physician, he observed, should be the family counsellor, and in particular should be consulted in regard to all matrimonial plans. When a new being was brought into existence its proper nutrition should be looked after from the very beginning—even prior to birth. After birth the security of the infant depended upon the proper appreciation of its proper feeding. One danger which had to be guarded against was that of overfeeding, which was apt to lead to infantile obesity and giantism. On the other hand it was necessary to give sufficient nutrition to provide for growth as well as life. After maturity was reached less food was required, for it was only necessary to furnish nutrition that was needed for the maintenance of life. Food, like alcohol, was used too much for pleasure rather than the maintenance of life. Stimulants, the speaker went on to say, were of value if used in the right way and at the right time, but in the healthful condition they were not needed. They were essentially a luxury, and all luxuries should be used with the greatest care, only the thoroughly healthy being able to indulge in them at all freely. The use of tobacco, especially when the smoke was inhaled, as it usually was by cigaret smokers, he maintained, did even more harm than the abuse of alcohol.

Proctologic Diseases.—A symposium of papers on proctologic subjects followed, the first being one by DR. JOHN L. JELKS, of Memphis, Tenn., on **The treatment of perirectal abscesses**. The author maintained that these abscesses when properly treated were not so serious as when poulticing was in practice and that they need not necessarily

result in fistula. The walls, he pointed out, were not got rid of when simply incised and drained; thorough curetting was also essential. The next paper was by DR. J. RAWSON PENNINGTON, of Chicago, who described a simple operation for the **Enucleation of hemorrhoids**, each quadrant being grasped with a pair of T-forceps, and the hemorrhage being controlled by torsion and rubber-covered tampon. He contended that there was less pain and that earlier recovery could be relied on by this method than by any other. DR. STERLING B. TAYLOR, of Columbus, Ohio, who read the third paper of the series, dealt with the subject of **Obstipation**. Defining obstipation, constipation, and costiveness, he proceeded to classify the causes of the first-mentioned complaint, principal among them being hypertrophy of the rectal valve. He defended Martin's views and methods. The discussion on the papers was opened by DR. JOSEPH M. MATHEWS, of Louisville, Ky., who said he had been very much interested and entertained by the papers, and that of Dr. Jelks he wished to commend very highly. When fistulas were at all complicated, no man could say that he could cure them by a first operation; therefore, if they could prevent them they should certainly do so. Dr. Pennington had also given them a number of useful suggestions, but he did not agree with his method of treatment. He used to excise tumors, but he had ceased to do so because of the severe hemorrhages which ensued, and had gone back to the old method of the ligature. He admitted that excision was the ideal method, or at least would be so were it not for the danger of hemorrhage, and if Dr. Pennington had discovered a means of effecting it without that danger he had done a great thing. He suggested, however, that to make the operation safe it would be well to bring the parts of the mucous membrane together and suture them. As to the last paper he remarked that if they substituted the word "constipation" for "obstipation" it would convey a better idea of the complaint, and many old country doctors would tell them how to cure it. The authorities made no mention of these rectal valves about which they had recently been hearing so much, and for his part he did not believe in their existence. Folds no doubt there were, but they could not have the effect attributed to them. He would certainly await further developments before adopting the new procedure which was known as "valveotomy." Several other speakers said they had been very anxious to see those rectal valves, but had never succeeded in doing so. DR. PENNINGTON, in replying to criticisms, said if he could not control a hemorrhage by torsion he would use a ligature, but he had never found it necessary to do so. DR. TAYLOR maintained that the question of obstipation had been dodged by those who did not admit the existence of rectal valves while acknowledging that every one had what they preferred to call folds.

THIRD DAY'S PROCEEDINGS.

Address in Surgery.—This was delivered by DR. C. A. WHEATON, of St. Paul, Minn. He devoted himself principally to the subject of **appendicitis**, which he claimed was essentially a disease for the surgeon to deal with.

Tuberculosis of the Spine.—A paper on the treatment of this disease was contributed by DR. ALEX. C. WIENER, of Chicago. He entered a plea for early diagnosis before deformity was visible, extension and hygienic treatment being essential if complications, such as paresis and gravitation, were to be avoided. He exhibited a specimen showing the possibilities of Cobat's forcible correction of the spine, and described cases of psoas abscess which had been cured by injections of carbolic acid, accompanied by other treatment.

DR. H. HORACE GRANT, of Louisville, Ky., followed with a communication on the medical and surgical treatment of **acute and chronic lymph-nodes**. Having referred to the useful purposes served by the lymphatics, he said they should not be removed except for good and sufficient cause. When they became diseased and useless there should be no hesitation about taking them out. In the course of the discussion which followed DR. WHEATON protested against the indiscriminate use of the knife in the case of affected glands, his belief being that the majority of cases would get better with proper hygienic surroundings and internal medicine.

Cocain-Anesthesia of the Spinal Cord.—DR. CARL H. ANDERSON, of Chicago, reported a number of cases in

which this operation had been performed, and discussed the physiologic and clinical results of the procedure. While advocating the operation, he warned the profession against the dangers it involved, chiefly because of the difficulty of obtaining a sterile solution. He had tried in vain to get a sterile solution by Tuffier's method, though he had succeeded in doing it by a process of his own. DR. MOYER gave a demonstration of the technic of the operation as performed by Dr. Anderson. If he were asked his advice as to this method of anesthesia he would say with their present knowledge, and having regard to the delicacy of the operation and other circumstances, "Don't do it." At the same time the subject was a fascinating one and incalculable benefits would result from the procedure if it could be freed from some of the dangers now attending it. Therefore, further experimentation was desirable, but it should only be carried on in well-equipped clinics.

Hip-Joint Diseases.—DR. A. M. PHELPS, of New York, read a paper on the **Treatment of tubercular and purulent hip-joint diseases with large speculum drainage and pure carbolic acid.** All abscesses, he said, should be opened as soon as diagnosis was made, for the purpose primarily of exploration, and secondarily for drainage and any surgical operation which might be deemed advisable. The action of the carbolic acid on the skin and tissues was neutralized by the use of pure alcohol. Incidentally it was brought out that carbolic acid was a specific for erysipelas. The profession was much indebted to Dr. Seneca Powell, New York, for discovering the antidotal properties of alcohol as regarded carbolic acid, thus rendering the latter available for use in the ways indicated as well as in others.

Pulmonary tuberculosis in infancy and childhood was discussed in a paper by DR. FRANK P. NORBURY, of Jacksonville, Ill. Heredity was a factor, but not so important a one as was sometimes thought. Infection was the most common source of the disease. The principal avenues of infection were the respiratory and intestinal tracts. Other diseases, as was well known, paved the way for the infection. House pets frequently introduced it into a household; therefore care should be taken of cats, dogs, and other domestic animals which feed upon tuberculous meat. The author then proceeded to discuss the parts that hygiene, climate, and symptomatic treatment played in the cure of the disease.

DR. STEIN, of Chicago, in discussing the paper, advocated intratracheal injections of oil to relieve patients whose stomachs were liable to be upset by taking it by the mouth.

The physician as a sanitarian was the subject of a paper by DR. HUGH A. COWING, of Muncie, Ind. While many physicians rendered invaluable services to the community by the attention they devoted to the cultivation of sanitation, there were others whom he considered criminally negligent and careless, and were often the means of spreading infection.

The Girl at Twelve.—This was the title of a paper by DR. J. H. TAYLOR, of Indianapolis, Ind. Discussing the management of girls at the age of puberty, he laid stress on the bad effects of manual labor and overwork in school, contending that physical and mental overexertion were alike to be deplored. Emmenagoges should be avoided in the case of girls at this period, and more attention paid to the general health. He appealed to mothers and physicians to unite in giving more care to girls entering on the stage of womanhood, as by so doing they would prevent many diseases which now so frequently resulted from lack of care and excess of work or study.

Asthma.—DR. R. A. BATE, of Louisville, Ky., in discussing this subject, quoted the saying of Loomis that the primary cause of asthma is undoubtedly some constitutional idiosyncrasy, and also the remark of Haig that asthma represents one of the effects of uric acid on the circulation. The curative treatment consisted of diet, hygiene, and anti-lithic measures. DR. THOMAS H. STUCKY, of Louisville, Ky., said the primary causes of asthma were imperfect salivation or mastication. Personally he knew when he was going to have an attack of asthma, not by how he felt, but by what he ate. Asthmatics were fond of sweet, starchy food, they were people of full habits, and they were lazy. He confessed that he filled the bill all through. DR. C. L. MINOR, of Asheville, referred to the relation between asthma and tuberculosis. He believed every asthmatic had uric acid, and pulmonary patients who had uric acid were fortunate. In this respect

asthma was like gout. They probably knew of the physician who told a patient he had the choice of dying of gout or tuberculosis. The patient chose gout, and showed his wisdom by so doing, because he lived much longer. Gout and asthma were alike favorable symptoms in pulmonary patients.

Curability of Inebriety by Medical Treatment.—DR. T. D. CROTHERS, of Hartford, Conn., read this paper, in which it was maintained that inebriety was a neurosis, usually self-limited, and very largely curable. The craze for drink was symptomatic. The real causes were central nerve-irritation, exhaustion, poisoning, and starvation. The success of medical treatment depended upon accurate knowledge of the causes and conditions present in each case, and the accurate application of general means and measures for their removal. Each case required special means and measures particularly adapted to meet the conditions present. The family physician as well as the specialist should treat these cases successfully. The stopping of the use of spirits should always be followed by medical treatment, but it was necessary to guard against the substitution of drugs which would produce even worse effects than alcohol. When properly treated as a disease a degree of cure far beyond expectations would be obtained, and when it was so recognized the family physician and not the clergyman or the quack would be called on to advise in such cases.

The Suprarenal Capsule.—DR. W. H. BATES, of New York, contributed the results of some further observations he had made on the clinical application of this drug, the aqueous extract of which he said was the most powerful astringent hemostatic and heart-tonic known. It lessened the congestion of the eye and other organs. The extract was not irritating or poisonous, and, unlike other powerful drugs, it was never contraindicated. There was no remedy which was so useful in all forms of inflammation. DR. J. A. STUCKY, of Lexington, Ky., said he had obtained excellent results from the use of the suprarenal liquid combined with chloretone, particularly in middle-ear complaints and hay fever.

The Philosophy of the Science and Art of Medicine.—In this paper DR. WILLIAM F. BARCLAY, of Pittsburg, Pa., showed the value of approaching the study of medicine from a purely philosophic point of view. The philosophy of medicine was the comprehension of the truth in the investigation of the science enabling one to arrive at rational conclusions in the study of the physical laws which governed organized matter in their normal and pathologic condition.

New Office Bearers and Next Place of Meeting.—The following were elected the office-bearers of the association for the ensuing year: President, Dr. A. H. Cordier, Kansas City, Mo.; first vice-president, Dr. Charles F. McGahan, Aiken, S. C.; second vice-president, Dr. C. L. Minor, Asheville, N. C.; secretary, Dr. Henry E. Tuley, Louisville, Ky.; treasurer, Dr. Dudley S. Reynolds, Louisville, Ky.; the last two being reelected.

It was arranged to hold the next meeting at Put-in-Bay, Ohio, on September 10, 11 and 12, 1901. Dr. J. C. Culbertson, Cincinnati, was appointed Chairman of the Committee of Arrangements.

Drs. Wheaton, Lanphear and Moyer were appointed delegates to the Pan-American Medical Congress to be held at Havana in December.

The proceedings were brought to a close by a banquet in the Battery Park Hotel.

Aphasia and Mental Confusion Caused by Cerebral Cyst.—John Lindsay Steven and James Luke (*Glasgow Medical Journal*, September, 1900) report a case, interesting because of completeness of recovery and of the clear indications for operation. The patient had an incomplete paralysis of the right arm and was clearly word-blind and also word-deaf. There were no certain indications as to the nature of the lesion, although on the whole the phenomena suggested the presence of hemorrhage. Trephining over the left motor area was determined on after the development of convulsive spasms, limited to the right side of the face. A large hemorrhagic cyst, situated in or over the left cerebral hemisphere, was exposed and evacuated. A few days afterward the patient recovered the power of speech and the use of his arm and has remained well since. [G.C.C.H.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Calendar of Meetings of Philadelphia Medical Societies for the week ended October 27, 1900:

Monday, October 22—Neurological Society.
Wednesday, October 24—County Medical Society.
Thursday, October 25—Pathological Society.

Fountain Springs State Hospital.—The legislature will be asked to appropriate \$50,000 for the erection of an annex to this institution.

Dr. Maurice H. Richardson, of Boston, will be the guest of the Medical Club of Philadelphia at the Hotel Bellevue, on Friday evening, October 26, 1900.

Pennsylvania Hospital.—Dr. Francis Stuart has resigned as superintending physician at the Pennsylvania Hospital and Dr. Charles Mitchell, of Wilkesbarre, senior resident physician, has been appointed his successor.

Scarlet Fever and Diphtheria.—In Lancaster, Pa., these diseases are said to be spreading rapidly among school children. The authorities say the spread of the diseases is due to the carelessness of persons residing in infected houses.

Warrants for Oleo Dealers.—Warrants have been issued in Pittsburg for the arrest of 419 dealers of oleomargarin. It is said that of 800 samples of butter examined, 498 were found to be oleomargarin. In all, 647 suits have been instituted.

Physician Infected at Autopsy.—It is reported that Dr. J. M. Simpers, of Germantown, Pa., is at Baltimore Medical College suffering from an infection in his right hand contracted while performing an autopsy. The result will be the loss of the second finger.

Report of Immigrants Inspected at the Port of Philadelphia, Pa., during the Month of September, 1900.—Total number inspected, 1,443; number passed, 1,403; number certified for deportation on account of dangerous contagious or loathsome diseases, or for other physical causes, 40.

Memorial.—Mrs. S. Weir Mitchell, wife of Dr. S. Weir Mitchell, of Philadelphia, will endow the University of Pennsylvania with a memorial to her daughter, who died about 2 years ago. Just what form the gift will take has not been announced, but it will probably be in the shape of a wing to the University Hospital buildings. This will form an important addition to the hospital, which has doubled its capacity during the last 6 years.

Vacancy in Professorship at University of Pennsylvania.—Owing to the election of Dr. Edward Martin to the professorship of clinical surgery in the University of Pennsylvania, the position of clinical professor of genito-urinary diseases in that institution is vacant. Individuals desiring to be considered as candidates for the position may send notice of such desire to the Rev. Jesse Y. Burk, secretary of the Board of Trustees, 400 Chestnut street, Philadelphia, before November 10, 1900.

Floating Quarantine Hospital.—The schooner *Georgie Clark*, recently bought by the United States Marine-Hospital Service, has been turned into a floating quarantine station at Philadelphia. She will be equipped with disinfecting chambers, supplemented by a sulphur furnace for fumigation by sulphur dioxide, and tanks and pumps for bichlorid solution. This equipment will be placed on deck, so that while in operation in a hot climate it will not be necessary for any of the work to be done in the hold of the vessel. The *Clark* will go to Cuba or Puerto Rico.

Must Report Disease.—Chief J. Lewis Good, of the Bureau of Health, has mailed a printed circular to each practicing physician in Philadelphia, notifying him of the regulations of the Bureau concerning contagious diseases, bac-

teriology, pathology, and disinfection. It states that cultures and other materials sent to the police station houses or the Detective Bureau will be forwarded to the division of bacteriology at once, on request of physicians. Diphtheria antitoxin as well as diphtheria culture outfits can be obtained at the same places, day or night, free of charge.

Medico-Chirurgical College.—The Board of Trustees has elected Edward M. Paxson, former Chief Justice of the Supreme Court of Pennsylvania, president of the college, and recommended measures that will cause a complete change in the policy of this progressive institution. The Board of Trustees has heretofore consisted of 15 members, 9 of whom were elected by the faculty of the college from its membership, and one as a representative of the alumni, while the remaining 5 members were laymen. The trustees have felt for some time that the interests of the college could be better served by the withdrawal of the members of the faculty from the board and the filling up of their positions by laymen. In consequence Judge Paxson will have associated with him such a Board of Trustees.

Change in Mortality.—While the death-rate from some diseases in Philadelphia has diminished during the last 18 or 20 years in others it has greatly increased. During the last 21 years the city's mortality from cancerous diseases has increased about 31%; from pneumonia, 60%; from diphtheria, 66%, and from kidney diseases, about 175%. On the other hand the diminution of the death-rate from pulmonary tuberculosis in 18 years is about 31%. The average death-rate from typhoid fever from 1892 to 1898, inclusive, was about 40% less than the 7 years immediately preceding. There has, however, been a slight decrease in the entire mortality-rate of the city, though not so great as the falling off in the amount of general sickness might lead one to expect.

Better Clinical Instruction.—At a recent meeting of the Board of Charities and Corrections of Philadelphia it was resolved to enlarge the scope of clinical teaching of the Philadelphia Hospital, and under regulations arranged with the superintendent is to be an obligation assumed by every member of the visiting staff, and can only be omitted by members of the staff after special arrangement with the superintendent.

Among the appointments made by the board were those of Dr. Joseph McFarland, of the Medico-Chirurgical College, and Dr. Simon Flexner, of the University of Pennsylvania, as pathologists at the Philadelphia Hospital; Dr. R. F. Sonnenkamp, as assistant physician in the insane department, and Dr. Robley D. Newton, as surgical registrar.

A Case in Medical Jurisprudence.—In Court of Common Pleas No. 1, of Philadelphia, there has been filed an action of peculiar interest to the legal and medical professions. The Statement of Claim as filed on behalf of Peter B. Sprenkle and wife, is for damages to the amount of \$50,000 against the Munyon's Homeopathic Home Remedy Company, and avers they were influenced by an advertisement appearing in various newspapers to the effect that "Munyon's skilled specialists are at your service for the mere asking," and that "Munyon's doctors are free at 1505 Arch Street." The plaintiff's claim is based on the alleged fact that Rebecca E. Sprenkle applied at the office of the defendant company, and while suffering only slightly from pains in her head, was induced by Dr. W. S. Moat, an agent, employe, and representative of said defendant company, to be treated for an alleged serious internal trouble, for which treatment she paid \$30 in a period covering from April 7, 1900, to June 2, 1900, and that the treatment, medical and surgical, was of such a nature as to wreck her health and produce permanent ventral hernia, and that she was immediately thereafter compelled to seek the advice of another physician and retire to a hospital where she was obliged to remain for a great length of time, and has since become a confirmed invalid.

Philadelphia Pediatric Society.—At the meeting on Tuesday, October 9, 1900, Dr. W. O. XANDER exhibited 2 boys, 8 years of age, who developed, a week apart, attacks of acute nephritis with great dropsy, the urine containing large amounts of albumin, blood, renal epithelium and casts.

Mumps existed in the neighborhood and there had been in these cases some swelling near the angles of the jaws, which had disappeared when the cases were seen, so that it was thought possible for the nephritis to have been secondary to mumps. In the discussion DR. GRIFFITH said that so many conditions simulated mumps that the history was not sufficient upon which to base a diagnosis of mumps. DR. WELCH was of the same opinion and thought that the cases might easily have been scarlet fever, the rash and desquamation having disappeared. DR. STENOEL, who saw the patients with Dr. Xander, was of the opinion that they had glandular fever primarily with secondary nephritis; mumps could be excluded by the history of the location of the swellings, and scarlet fever was considered, but no rash had been seen and there was no trace of peeling.

DR. T. S. WESTCOTT gave formulas illustrating a method for the **Differential Modification of the Proteids of Cow's Milk in Percentage Mixtures.**

DR. MACLACHLIN presented a patient, an infant 24 days old, with a rapidly destructive syphilitic lesion of the upper lip, the greater part of the right half being destroyed; the right eyeball was sunken in the orbit and there were ulcers on the mucous membrane of the right cheek; a large nevus covered the right side of the face and the right scapula. In the discussion, DR. SCHAMBERG thought that the distribution and character of the lesions pointed to some trophic origin rather than to syphilis.

DR. F. A. PACKARD read the **Report of the Milk Commission**, which appears in another column of the JOURNAL. DR. M. OSTHEIMER reported a case of **fatal intestinal hemorrhage** of unknown origin in an infant of 5 months; autopsy showed no ulceration in any part of the alimentary tract.

DR. J. H. JORSON exhibited a **larynx with a stricture** extending from below the vocal cords to the cricoid cartilage, removed from a boy 5 years old, who had had to wear an intubation tube for 41 days after membranous croup; when the tube was removed dyspnea and cyanosis began to come on with increasing severity; as the smallest sized intubation tube could not be inserted tracheotomy was done; an attack of measles developed with pneumonia, terminating fatally; the stricture scarcely admitted a small grooved director. The treatment of "retained tubes" was dwelt on.

Vital Statistics of Philadelphia for the week ended October 13, 1900:

Disease.	Cases.	Deaths.
Total mortality	338	
Inflammation of appendix 1, bladder 2, brain 7, bronchi 4, kidneys 9, liver 1, lungs 14, peritoneum 7, pleura 1, stomach and bowels 12, tonsils 1		59
Lungs—tuberculosis of 55, hemorrhage of 1, congestion of 3		59
Debility 3, marasmus 17, inanition 7,		27
Heart—disease of 21, fatty degeneration of 1		22
Carcinoma of bladder 1, breast 3, liver 2, rectum 1, stomach 5, throat 1, uterus 3, sarcoma of leg 1, stomach 1, liver 1		19
Diphtheria	99	16
Brain—diseases of 2, congestion of 3, hemorrhage of 5, tumor of 2, softening of 1		13
Uremia 9, Bright's disease 4		13
Old age		13
Casualties		11
Typhoid fever	49	10
Cholera infantum		10
Liver—cirrhosis of 7, fatty degeneration of 1		8
Paralysis 5, apoplexy 3		8
Convulsions 4, puerperal 1		5
Drowned		4
Poisoning—phosphorus 1, strychnin 1, puerperal 1		3
Diarrhea 1, dysentery 2		3
Abscess of liver 1, pelvis 1		2
Suicide—carbolic acid 1, illuminating gas 1,		2
Scarlet fever	24	1
Aneurysm of aorta 1, atheroma 1, colic 1, membranous croup 2, cyanosis 1, abdominal dropsy 1, epilepsy 1, erysipelas 1, fracture of thigh 1, senile gangrene 1, hemorrhage of bowels 1, umbilical hemorrhage 1, jaundice 1, rheumatism 1, spinal sclerosis 1, surgical shock 1, septicaemia 2, syphilis 1, tabes mesenterica 1, tetanus 2, whooping-cough 2		

Pittsburg Academy of Medicine.—At a meeting held October 8, DR. E. W. DAY read a paper on **The sequelae of middle-ear suppuration, with a report of 4 cases.** The serious nature of the condition which may follow a chronic suppurative process in the middle ear, and the anatomic relations which favor their development were pointed out. These are: (a) Purulent meningitis; (b) extradural abscess; (c) sinus thrombosis; and (d) cerebral or cerebellar abscess. When there is free drainage through the external auditory canal, such sequelae are not apt to follow, but so long as the middle-ear is the seat of an inflammatory process, extension to the cranial cavity through its bony walls is always possible. Not infrequently intracranial involvement occurs so slowly, and gives rise to so few symptoms, that it is entirely overlooked until an acute exacerbation of the inflammatory process in the ear aggravates the condition and produces a lesion sufficiently extensive to give rise to the characteristic symptoms. It is a common error to consider the virulence of the infection proportionate to the odor of the purulent discharge. To quote MacEwan, "as purulent otitis media and the extension of the inflammatory process to the mastoid antrum and cells is the primary focus which leads most often to intracranial inflammatory lesions, the eradication of the otitis media must be regarded as the most potent factor in the prophylaxis of inflammatory cerebral lesions." To wait until symptoms of intracranial involvement appear frequently sacrifices the life of the patient. Purulent meningitis is the least amenable to surgical treatment, as the symptoms appear so suddenly and the inflammatory process spreads with great rapidity. A fatal case of this complication was reported in the person of a girl who had suffered destruction of the tympanum, and partial loss of the malleus following scarlatina years before. There was no discharge and no granulations, and the inflammatory process seemed to have long since subsided. At operation the inner wall of the antrum was found eroded, exposing the dura, and pus oozed from between this membrane and the bone. Extradural abscess, when localized and promptly evacuated, gives the best results, the mortality being quite low. A case previously reported was referred to. The diagnosis and operative treatment of lateral sinus thrombosis were considered at length, and two cases reported. In operating for this condition the most rational procedure is to ligate the jugular vein below the seat of thrombus and dissect it out up to and including the lateral sinus as far as thrombus extends. DR. M. R. WARD, speaking on the same subject, said that cerebral and cerebellar abscess are almost always traceable directly or indirectly to a suppurative process in the middle ear. The tympanic and cerebral cavities are separated by a thin, bony partition, which is often the seat of a necrotic process. This is especially true of old and neglected cases of a suppurative character, and is to be regarded with the greatest apprehension. If the inner wall of the attic be involved, the cranial cavity may be infected by perforation. If the mastoid is affected the lateral sinus is in danger. The following cases were re-reported: (a) Epidural abscess following infection from the middle ear which burrowed backward and perforated the occipital bone $1\frac{1}{2}$ inches back of the mastoid without involving the brain proper. Operation was followed by recovery, and the patient was presented for examination. (b) Epidural abscess over temperosphenoidal lobe from perforation upward through roof of auditory canal. Entering the cranial cavity through the mastoid which was free from pus, two drams of pus were evacuated at operation. Patient died. (c) Pyemia with metastatic abscesses in almost all the joints of the body due to a purulent otitis media. Death. (d) Localized meningitis of otitic origin. Mastoid opened and a quantity of pus evacuated. Severe cranial symptoms, including aphasia, followed, with ultimate recovery. The great danger in operating upon this class of cases is not in doing too much, but in doing too little. Every vestige of necrotic tissue must be removed. In closing, Dr. Day said that if a culture made from a case of purulent otitis media showed streptococci, we might expect serious complications. Other bacteria are of little prognostic importance. Symptoms are very unreliable, but it is wise to record pulse and temperature every 2 hours night and day. Dr. Ward concurred in the slight value of symptoms, and instanced his case of pyemia in which the temperature, 2 days after admission, was never above 100.4° F., and the greater part of

the time was 99° or less. Wilde's incision is a very doubtful surgical procedure, but in some cases is sufficient. A case was cited as an example. Cerebral complications are possible without perforation of the bony plate, but not probable. Dr. WILLETS contended that the case cited by Dr. Ward in justification of Wilde's incision did not show that it was of any value, as the outer wall of the mastoid had already been perforated before incision was made.

NEW YORK.

Home for Aged Men.—The late Samuel Pringle, of New York, left a fund of \$250,000 to erect and maintain a home for old men who were once rich, but have lost their fortunes.

Bequests to Charity.—By the will of the late Ignatz Hoff, of New York, the following institutions each receive \$5,000: St. Joseph's, Columbus, and St. Francis Hospitals, and the German Hospital and Dispensary.

Physician Found Wounded.—Dr. Joseph W. Dwyer, a physician of Passaic, N. J., and house surgeon in the general hospital there, was found in a dying condition in an araway of that city October 13. Whether he fell or met with foul play is not evident.

Bullets Cause Insanity.—An autopsy performed on the body of George Reimherr, who died in the insane pavilion of Bellevue Hospital recently, showed that the man's insanity had been caused by 2 revolver bullets which were lodged in his head. They had been imbedded there for 2 years.

Trinity Hospital of New York, which has been closed since May for repairs, was reopened October 15. This hospital, which has been under the management of the Sisters of St. Mary for many years, will, in the future, be under a secular superintendent, the Sisters having withdrawn.

Private Charities.—Applications have been received by the Board of Estimates of New York from private charitable institutions. St. Joseph's Asylum asked for \$90,000; St. Joseph's Institute for \$30,900; the Actors' Fund for \$20,000 and the Washington Square Home for Girls for \$9,859.

Dr. S. Baruch, of New York, has been awarded a silver medal for his efforts in behalf of free public baths by the jurors of the Paris Exposition of 1900. Chicago, Buffalo, and (prospectively) New York are the only cities in the world that provide free cleansing baths, with soap, hot water, and towels.

Memorial Hospital at Oneonta.—The corner-stone of the Aurelia Osborn Fox Memorial Hospital at Oneonta, N. Y., a gift of Mr. Reuben L. Fox, in memory of his wife, was laid with Masonic ceremonies on October 5. The hospital is designed to be a beautiful structure erected according to the most approved sanitary and scientific plans.

New York Obstetrical Society.—At the annual meeting of this society, held October 9, 1900, the following officers were elected for the ensuing year: President, Dr. H. J. Boldt; first vice-president, Dr. Ralph Waldo; second vice-president, Dr. H. N. Vineberg; recording secretary, Dr. G. L. Brodhead; assistant secretary, Dr. G. G. Ward; corresponding secretary, Dr. E. E. Tull; treasurer, Dr. J. Lee Morrill; pathologist, Dr. W. S. Stone.

Correction by Dr. A. L. Benedict.—Dr. A. L. Benedict, of Buffalo, writes: "The report of my paper on eye-strain, read before the Buffalo Academy of Medicine, and published on page 615 of your issue of October 6, is liable to give a wrong idea of my views. For instance, the first sentence, which correctly expresses my belief that eye-strain is an infrequent cause of chronic gastric symptoms, might from the context be understood to claim that eye-strain is the result of gastric disturbances, a manifest absurdity. As Dr. Jones and Dr. Starr were not at the meeting I do not understand how they could have taken part in the discussion. While conceding that eye-strain may be the last straw in producing gastric subacidity, nausea, etc., I hold that this etiologic relation should not be taken for granted, but should be established by exclusion, after using other methods of

diagnosis. Barring the fact that my language was misunderstood in one particular by one of the discussers, the discussion showed a surprising harmony of opinion, though the relative frequency with which gastric symptoms and eye-strain should be regarded as coincidences, and as related, as effect and cause, naturally appeared differently according as one looked at the matter from one or the other standpoint, without being able to follow up many cases with the combined experience of oculist and digestive specialist."

NEW ENGLAND.

The American Humane Association has awarded a prize of \$125 for the third best essay on "Vivisection; Its Abuses and Their Remedy," to Arthur W. Towne, of Amherst College.

Typhoid at Newport.—An epidemic of typhoid fever is reported at Newport, R. I. The city has no Board of Health composed of medical men; the Aldermen act in that capacity. The Newport Hospital is full and a committee has been appointed by the Aldermen to arrange for the establishment of an emergency hospital. The city water will be examined.

Society Doctors' Hospital.—At a meeting in Springfield, Mass., of the delegates representing the United Protective Association, they voted to recommend to their respective societies that patients be sent to the Buscall Sanatorium. A rate has been made that will be good for all members of societies, and physicians employed by societies will be granted admission.

Yale Medical School.—Prof. Russell H. Chittenden, director of the Sheffield Scientific School, has been elected professor of physiology in the Yale Medical School. His relationship to the Sheffield Scientific School will not be affected. Dr. Yandell Henderson, who has been an instructor in the Sheffield Scientific School, will be Professor Chittenden's assistant in his work in the medical school.

A Vigorous Legal Decision.—The following important decision has recently been rendered by Judge Grime, of Fall River, in the case of Dr. Ezra R. Wilbur, clairvoyant physician, against a police officer, to recover for professional services. Judge Grime ruled in these words: "I am satisfied in my own mind that the services rendered were worse than valueless, and that had they been continued without change the defendant would have reaped his reward in death. Still, he employed the plaintiff and must pay the bill."—[*Boston Medical and Surgical Journal*.]

CHICAGO AND WESTERN STATES.

The County Hospital at Milwaukee will be remodeled and rebuilt at an expense of about \$100,000.

The Visiting Nurses of Chicago, during the summer months have cared for 2,096 patients, making 9,790 visits.

Rockford Hospital, Illinois, has received a bequest of \$1,000 from the estate of the late Elizabeth Hulse Moffatt.

Northwestern University Medical School.—Dr. August F. Lemke has accepted a position in the department of didactic medicine.

A Medical Defence Association has been formed by the physicians of Tippecanoe Co., Indiana, to secure reasonable promptness in the payment of bills.

For Disabled Soldiers.—It is probable that the hospital at Fort Logan, Colorado, will be rebuilt and made into a national sanatorium for sick and disabled soldiers.

The College of Physicians and Surgeons of San Francisco has added a postgraduate department to its curriculum. A new Polyclinic has also been organized in that city.

The Women's Medical School of Northwestern University began its fall term October 1, with the quota of 100 students, to which it is limited. Mary G. McEwen, lecturer on anatomy, has been added to the faculty.

Anti-Fat Remedy.—A resident of Wabash, Ind., who 2 years ago weighed 350 pounds, is reported dying from ulceration of stomach and liver, caused by the antifat remedies which he used to reduce his obesity.

New Hospital at St. Paul.—Of the \$50,000 which is desired by the Norwegian Lutheran Synod to establish a hospital at St. Paul, Minn., \$10,000 has been raised. As soon as \$35,000 is subscribed work will begin on the structure.

The St. Clair Co. Medical Society of Illinois gave a pleasant surprise and reception to Dr. A. Berger, of Lebanon, on his seventy-ninth birthday. He was the founder of that Society and is the oldest practitioner in Southern Illinois.

St. Louis Hospital.—Plans for the new city hospital at St. Louis, Mo., are about complete. They include 1 octagonal ward 3 stories high, 1 isolation ward, 5 general wards, surgical room, kitchen and laundry, etc., with a large open court in the center.

The State Board of Health of Colorado, in a recent bulletin, disavows any intention to undertake a crusade against tuberculous individuals. It points out the danger that this class may be to the community and the means of preventing them.

Manila Hospital Appointment.—Dr. John R. McDill, of Milwaukee, Wis., for the past year major-surgeon of the Thirtieth Infantry, U. S. V., now in the Philippines, has been appointed chief operating surgeon of the Government Hospitals at Manila.

The Inland Empire Clinical Society held its first semiannual meeting in Spokane, Washington, recently. The following officers were elected for the ensuing term: President, Dr. J. W. Morris, of Lewiston, Idaho; vice-president, H. W. Mauzey; secretary, C. P. Thomas; treasurer, A. F. MacLeod.

Sanatoriums at Hot Springs.—A plan is under consideration to build a large sanatorium at Hot Springs for railroad men, and the Knights of Pythias are considering a proposition to build a \$250,000 sanatorium at that place. A committee of 5 representatives of the Supreme Lodge is endeavoring to raise the funds.

Arkansas Hot Springs.—An interesting report on the Hot Springs Reservation in Arkansas has been made by the superintendent, Martin A. Eisele. He says there were 50,000 visitors during the season. The income to the Government from water and groundrents amounted to \$18,670. The reservation includes 911 acres, and in this tract there are 157 Government lots still unsold. These lots have been appraised at \$75,000. The amount of water distributed to each bathhouse is scrupulously controlled and the public protected from monopoly and extortion by the schedule of charges provided by the Secretary of the Interior. The free Government bathhouse is of great benefit to indigent sufferers, who otherwise would not have the benefit of the waters. The record for the year shows 9,508 applications for free baths, of which only 216 were refused.

SOUTHERN STATES.

The Hebrew Hospital and Asylum of Baltimore received donations to the amount of \$2,500 at the thirty-third annual Succoth Festival held October 14.

Insane Veterans.—St. Elizabeth's Insane Asylum at Washington recently received 16 insane soldiers, veterans of the Civil War, from the Soldiers' Home at Milwaukee, Wisconsin.

Naval Surgeon Lippitt, of Washington, who was on duty in Peking during the siege of the legations, was badly wounded in the left thigh, the bone being fractured. The leg has been shortened about 3 inches.

General Inspection of Pupils to be Instituted.—On account of reported prevalence of disease in several country parishes, the New Orleans City Board of Health has decided to examine all pupils now in attendance in the public schools of the city.

A Korean Woman Physician, Mrs. Pak, was recently graduated from the Woman's Medical College, Baltimore. Her first instruction was received at a mission school in Seoul. She has returned to Korea, where she intends to engage in medical missionary work.

Old Quarantine Grounds for Sale.—It is reported that the old quarantine grounds on the shore of the Potapasco River, just opposite Fort McHenry, are for sale. At one time this property was estimated to be worth \$100,000. The proceeds may be used to help erect a hospital for infectious diseases in Baltimore.

Baltimore Council Wants Hospital.—At a meeting of the Baltimore Council recently an amendment to the ordinance providing for the sale of the Eastern Potter's Field was offered, which provides that the money received from the sale of the ground shall be used to help in the erection of a hospital for contagious diseases.

The Ophthalmological and Otological Society, of Washington, D. C. (Dr. S. O. Ritchey, president), held its first fall meeting for 1900, October 9, at the residence of Dr. W. K. Butler, who read the paper of the evening, entitled "The Necessity for Wearing Glasses," which was well received and heartily responded to by the members.

Springfield Hospital for the Insane.—At a meeting of the board of directors of this institution at Sykesville, Md. recently, it was decided to fit up a room in the institution as an operating room. Inquiries have been made in regard to the admission to the institution of feeble-minded and idiotic children. The board decided against the admission of such patients.

Regulation of Marriage.—The Tristate Medical Society of Tennessee, Alabama and Georgia, recently in session in Chattanooga, Tenn., has taken steps to secure medical legislation in those 3 States for the purpose of regulating or prohibiting the marriage of habitual criminals, persons afflicted with incurable diseases, drunkards, and victims of harmful drugs.

The Clinical Society of Washington, D. C., after its usual summer vacation, reconvened at 1121 Fourteenth street, N. W., October 8. DR. WALLACE JOHNSON read an interesting paper on **Clinical pathology**, in the discussion of which many of the 25 members present engaged. The following officers were elected for the ensuing year: Dr. Charles C. Marbury, president; Dr. Duff G. Lewis, vice-president; and Dr. J. Carlisle DeVries, secretary and treasurer.

Richmond (Va.) News.—Owing to the large number of cases of typhoid fever in the State and city, the Richmond Academy of Medicine, at a recent meeting, discussed the subject freely. The principal speaker of the evening advanced the idea that its prevalence was due to the long hot dry summer, followed by pouring rains, which flushed and flooded the lands, thereby carrying germs to the drinking water. The number of cases reported in this city for September, 1899, was 21, with 6 deaths; for September, 1900, 44 cases, with 15 deaths.

The bids for the construction of the new Charlotte Williams Hospital have been received by the committee and work on the foundation will soon begin.

Orleans Parish Medical Society.—At the meeting, October 13, DR. C. JEFF MILLER read a paper on **A case of double intraligamentous cyst**, with remarks on the operative procedure in the case. Dr. Miller further outlined the plan to be pursued to avoid hemorrhage from the uterine and ovarian arteries in operating upon these cases. DR. S. P. DELAUP reported **A case of Raynaud's disease** which had sustained 10 amputations and was now about to undergo the eleventh, at his hands. Amputation has thus far been the only efficient means of relieving the intense pain. Gangrene had also to be contended with. DR. GORDON KING exhibited several specimens of **polypi** removed from the nasopharynx of patients at the Ear, Nose, and Throat Hospital, displaying several styles of snares and explaining the indications for the use of each.

Hospital Sites.—Dr. Woodward, in memoranda regarding sites for hospitals, recently submitted to the Commissioners

of the District of Columbia, is reported to have said that the site of Johns Hopkins University Hospital is equivalent to 1,679 square feet per bed, while the Edinburgh Royal Infirmary has but 829 square feet. Dr. Woodward quotes an authority who says that with a hospital of from 100 to 200 beds, 60 square yards per bed may suffice under very exceptional conditions, but with 300 to 400 beds the area should be at least 90 square yards per patient, and with 500 beds and upward 120 to 140 square yards per patient would be required; but it may be safely laid down that on a town site surrounded by houses it is not admissible to afford in any hospital less than 90 to 100 square yards per patient.

CANADA.

A Crematory is being built at Montreal. Arrangements have been made to accept Sir W. C. McDonald's offer to build and endow the institution.

Toronto University.—The department of Dr. J. J. Mackenzie, professor of pathology in the medical department, is being equipped at an expense of \$4,000.

Proposed Legislation for Inebriates in Ontario.—Before the conference of the Canadian Charities and Correction Convention, which assembled recently in Toronto, Dr. Gilbert Gordon, President of the Toronto Medical Society, outlined the plan for dealing with the inebriate class of the community. Bills is to be introduced into the Ontario Parliament at the next session. The Government will be called upon to appoint a superintendent whose duty it will be to organize the medical treatment of this class on the probation system. In cities of 20,000 or over a probation officer will be appointed who will have the supervision of inebriates under suspended sentence. Wards will also be arranged for in the General Hospitals of the province. The scheme has already been endorsed by the Ontario and Canadian Medical Associations.—[*Medical News*]

MISCELLANY.

Relief stations will be established at San Juan and Ponce, P. R., and at Honolulu, H. I., by order of the Surgeon-General.

Invalids from Manila.—On September 23 the transport *Sherman* with 411, and on October 2 the *Maude*, with 273 sick soldiers on board, left Manila bound for San Francisco.

American pharmacy is to be congratulated on account of the international recognition of American pharmaceutical literature. The Paris Exposition of 1900 has announced that the highest award (the Grand Prize) was bestowed upon Remington's Practice of Pharmacy. The work was exhibited by the publishers, J. B. Lippincott Co., of Philadelphia.

Hospital Care of Soldiers.—The Secretary of War has amended paragraph 1457 of the army regulations so as to provide that an officer or enlisted man on duty with any command or detachment who may require hospital care and treatment at a place where there is no army hospital may be taken to a civil hospital at rates not to exceed the usual local charges for like services to private patients.

Obituary.—ROSS RICHARDSON BUNTING, of Philadelphia, October 11, aged 66.—JOSEPH TREPP, of Adrian, Mich., September 25, aged 73.—SAMUEL S. DOWNS, of Waterville, O.—JAMES M. MONTMOLLIN, of Ashland, Ky., September 24.—EDWARD N. WEBSTER, of St. Louis, Mo., September 25, aged 52.—JOHN BOSWELL, of Colfax, Wash., October 11, aged 90.—DAVID PELLMAN BOYER, of Philadelphia, October 15, aged 76.

United States Navy.—Rear Admiral Van Reyepen, surgeon-general of the navy, reports that the health of the navy and marine corps has been good during the past year. The death-rate from disease has been less than the average for the same period. Owing to 21 deaths from gunshot wounds, the mortality-rate from injuries was somewhat increased. There are now 17 vacancies in the list of assistant surgeons. It is hoped that these vacancies will be filled so soon as it is generally known that recent legislation gave assistant surgeons in the navy the same rank as assistant surgeons in the army.

The American Electrotherapeutic Association will hold its eleventh annual meeting in Buffalo, N. Y., September 17, 18, and 19, 1901. The following is the list of officers for the ensuing year: President, Dr. Ernest Wende, Buffalo, N. Y.; first vice-president, Dr. Fred H. Morse, Melrose, Mass.; second vice-president, Dr. D. R. Braiser, Chicago, Ill.; treasurer, Dr. R. J. Munn, Savannah, Ga.; secretary, Dr. R. Buc, Harrisburg, Pa.

Yellow Fever in Havana.—In the systematic attempt to control the yellow fever outbreak in Havana, Major Gorgas and his staff inspect more than 600 houses daily, with the view of enforcing cleanliness. Since October 1, 113 new cases have been officially reported. The disease prevails in Havana to a greater extent than since 1897. The excess of mortality during the present year over the 2 preceding years is due to the fact that there are many more unacclimated persons in Havana now than at any time since 1897. The filthy condition of the harbor of Havana is believed to be largely responsible for the prevalence of the disease, and many medical men are of the opinion that the only effective measure that could be adopted would be the cutting of a tidal canal, which would allow the tides to flow back and forth through the harbor.

Marriage of the Deaf.—Prof. E. A. Fay has examined the records of 4500 marriages of the deaf and he discovers that, while taking the marriages of deaf persons as a whole, nearly 9% of the offspring are deaf, as contrasted with less than $\frac{1}{10}$ or 1% of deaf children as a result of the marriages of normal persons, a very different and much more favorable result is obtained if it be found that the deaf parents had no trace of previous deafness in their families. In cases of this kind Prof. Fay proves that the "marriages of deaf persons without deaf relatives is no more likely to result in deaf children than any marriage in the community at large;" while "the intermarriage of hearing persons who have deaf relatives is just as likely to result in deaf children as the marriage of the deaf." Intermarriage of blood relatives, with one or both defective, is very dangerous, and while Prof. Fay gives certain deaf mutes the hope of normal offspring, his study makes the evil possibilities of the marriage of defectives loom large.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended October 12, 1900:

SMALLPOX—UNITED STATES.				CASES.	DEATHS.
ALASKA:	Nome	Oct. 7	1	(in barracks.)

Changes in the Medical Corps of the U. S. Army for the week ended October 13, 1900:

WICK, Major WILLIAM B., surgeon, will proceed to the Philippine Islands on the army transport "Hancock," to sail October 1.

REYNOLDS, CHARLES R., acting assistant surgeon, is relieved from temporary duty at the Presidio and will proceed to Seattle, Wash., where he will report on the transport "Oopack" for temporary duty during the voyage to the Philippine Islands, for assignment to duty.

WESTERDAHL, GUS J., hospital steward, is assigned to temporary duty with troops on the army transport "Hancock," to sail for the Philippine Islands about October 1. Upon arrival at Manila he will report for assignment to duty.

REILLY, Lieutenant-Colonel ROBERT M. O., deputy surgeon-general, is granted leave of absence for 20 days.

JOHNSON, BORKE L., acting assistant surgeon, is relieved from duty in the division of the Philippines, and will proceed to Washington, D. C., and report to the Surgeon General of the Army for instruction.

JOHNSON, BURKE L., acting assistant surgeon, is granted leave of absence for 3 months, to take effect upon his relief from duty in the division of the Philippines.

TESSON, Major LOUIS S., surgeon, will report to the commanding general, department of the Columbia, for assignment to duty as chief surgeon of that department in addition to his duties as surgeon at Vancouver Barracks.

EMERSON, HERBERT, acting hospital steward, Fort Columbus, is transferred to Fort Dade to relieve Hospital Steward James V. Mackie.

MACKIE, JAMES V., hospital steward, will be sent to San Juan, P. R., for assignment to duty in the medical supply depot at that place.

VAN DYKE, WM. R., acting assistant surgeon, is relieved from duty at Jefferson Barracks, to take effect upon return to duty at that post from leave of Major Marshall W. Wood, surgeon, and will then proceed to Fort Thomas for duty.

WILSON, NELSON W., acting assistant surgeon, is granted leave of absence for 1 month.

KERVIS, JOHN NAN, hospital steward, Fort Duchesne, is transferred to Fort Washakie for duty.

The following named hospital stewards (appointed October 3, from acting hospital stewards) were assigned to duty at their present stations: OSCAR A. MANSEAU, Plattsburg Barracks; HARRY T. SMITH and HERBERT CURTIS, Army general hospital, Washington Barracks; GEORGE W. MCKENZIE, Fort Bliss; HUGH C. CLOVER, Fort Washington; HERBERT THOMPSON, San Diego Barracks; WILLIAM J. DONAHEY, Fort Morgan; JOSEPH C. MERRY, Fort Mott; JULIUS STRAUSS, Fort Hunt; JAMES J. COOK, Fort Casey; FREDERICK S. SIMMONS, Camp Osborne, Idaho.

MACCLEERY, HUGH R., hospital steward (appointed October 3, from acting hospital steward) now at Huachuca, P. R., will report to the commanding general, department of Puerto Rico, San Juan, P. R., for assignment to a station.

PHARES, WALTER L., hospital steward (appointed October 3, from acting hospital steward), now at Fort Myer, will be sent to Columbus Barracks for duty.

KILLIKELY, HENRY, hospital steward (appointed October 3, from acting hospital steward), now at Fort Harrancas, will be sent to Fort Screven for duty.

DODGE, DONALD B., hospital steward (appointed October 3, from acting hospital steward), now at Vancouver barracks, will be sent to Fort Duchesne for duty.

GATES, CHARLES, hospital steward (appointed October 3, from acting hospital steward), now at Vancouver barracks, will be sent to Fort Huachuca for duty.

WOODHULL, Lieutenant-Colonel ALFRED A., deputy surgeon-general, is granted leave of absence for 10 days.

BORDEN, Captain WILLIAM C., assistant surgeon, is detailed as a member of the examining board at Washington barracks, vice Captain Edward L. Munson, acting surgeon, relieved.

Changes in the U. S. Marine-Hospital Service for the week ended October 11, 1900:

WOODWARD, R. M., surgeon, has been detailed to represent the Service at the meeting of the American Public Health Association, to be held at Indianapolis Ind., October 22-26, 1900.

STONER, G. W., surgeon, is granted leave of absence for 7 days. October 9.

BANKS, C. E., surgeon, the 14 days' leave of absence granted by department letter of June 5 is revoked. October 10.

WHITE, J. H., surgeon, is granted leave of absence for 1 month. October 11.

COBB, J. O., passed assistant surgeon, to proceed to El Paso, Tex., on special temporary duty. October 9.

MATHEWSON, H. S., assistant surgeon, is relieved from duty at Philadelphia, Pa., and directed to proceed to San Juan, P. R., and assume command of the service, relieving Assistant Surgeon C. H. Lavinder. October 9.

LAVINDER, C. H., assistant surgeon, upon being relieved from duty at San Juan, P. R., to proceed to Washington, D. C., for orders. October 6.

WILSON, R. L., assistant surgeon, is relieved from duty at San Francisco, Cal., and directed to proceed to Honolulu, H. I., and report to Surgeon Carmichael for duty.

CLARKE, P. M., acting assistant surgeon, is granted leave of absence for 20 days from October 15. October 6.

GOLDSBOROUGH, B. W., acting assistant surgeon, is granted leave of absence for 1 day. October 11.

TUTTLE, JAY, acting assistant surgeon, is granted leave of absence for 30 days from October 24. October 11.

ALLEN, G. C., hospital steward, is granted leave of absence for 6 days from October 22. October 5.

SOUTHWARD, F. A., hospital steward, is granted leave of absence for 15 days from November 5. October 10.

MARR, HARRINGTON, of Tennessee, appointed acting assistant surgeon. October 2.

DOUGLAS, RICHARD, acting assistant surgeon, resigned October 7.

Changes in the Medical Corps of the U. S. Navy for the week ended October 13, 1900:

RICHARDS, T. W., passed assistant surgeon, detached from the "Indiana" and ordered to the "Alabama." October 16.

MORRIS, L., passed assistant surgeon, ordered to the Naval Academy.

MORGAN, D. H., assistant surgeon, detached from the "Vermont" and ordered to the Pensacola Navy Yard.

MURPHY, J. A., assistant surgeon, detached from the Pensacola Navy Yard and ordered to the Asiatic Station for duty on the "Don Juan de Austria;" to report at San Francisco, Cal., October 30, for passage on the "Solace."

HAAS, H. H., assistant surgeon, detached from the "Don Juan de Austria" and ordered home and to wait orders.

(Orders issued by the commander in chief of Asiatic Station.)

LUNA, G. A., passed assistant surgeon, detached from the "Monocacy" and ordered to the Cavite Naval Station.

THOMPSON, J. C., assistant surgeon, detached from the "Monocacy" and ordered to the Cavite Naval Station.

Foreign News and Notes.

GREAT BRITAIN.

Death by Plague at Cardiff.—A sailor who recently arrived on the Tyne from Rosario, A gentine R-public, became ill. He went to Cardiff, Wales, where he died October 7, of the bubonic plague.

Dr. Yersin, to whom the Academy of Moral Sciences recently awarded a prize of 15,000 francs in recognition of his services to the cause of philanthropy, has devoted the sum to his antiplague serum establishment at Nha trang.

Vaccination Cures Warts.—Dr. J. D. Staple, a public vaccinator of Bristol, gives a curious account of the cure of warts on the hands of a girl by vaccination. On one hand 94 warts were counted. In about 7 weeks after the operation the warts had gradually disappeared, leaving temporary white spots.

Diphtheria in Leicester.—The outbreak of diphtheria in Leicester is assuming serious proportions, no less than 73 cases having been notified in one week with 9 deaths. During a period of three months 444 cases were notified, as against 258 for the quarter ended in June last. A new isolation hospital has been opened.

Dowie in London.—The general secretary of the Medical Defence Union is reported to have said that England's medical men will ask the incoming Parliament to pass an act for the suppression of such humbugs as John Alexander Dowie, Chicago's divine healer. At present England has no law to fit this alleged healer's case.

Meath Hospital.—Richard Lane-Joynt has been elected surgeon to the Meath Hospital in Dublin in place of the late Sir William Stokes. Mr. Lane-Joynt has filled the position of assistant surgeon to the hospital for the past 7 years. He has devoted special attention to the study of x-ray skiagraphy, and was offered a position in this capacity on the staff of the Irish Hospital, but found himself unable to accept the offer.

A Female Military Medical Officer.—The Colonial Office has appointed Mrs. Hamilton Williams, M. B., B. S., to be one of the special service medical officers to the Ashanti force. She has distinguished herself greatly as Prideaux Scholar at the London School of Medicine for Women, and as the winner of the County Council research scholarship last year. We believe that Mrs. Williams is the first woman to occupy such a position in the British service.—[Medical Press.]

The Army Hospitals.—Sir William MacCormac, speaking in support of the Unionist candidate, said he was a Liberal, but he endorsed the position of the Unionist candidate in regard to the war. He went to South Africa in sympathy with the Boers, but experience in the country altered his opinions. The Army Medical Service was much undermanned, but as to the charges against hospitals the man who made them ought to have made them on the spot. The work done by the medical staff was beyond praise.

The Plague.—The latest reports regarding the position of the plague in Glasgow are most satisfactory. There have been no new cases for over 2 weeks. In Belvidere Free Hospital 21 cases of plague and 2 suspected cases remain. The number of contacts in the reception-houses has been now reduced to 19. Experience in India has established the fact that the so-called puerperal type of plague is an especially fatal form, and the observation would appear to be confirmed in Glasgow. The police authorities in Glasgow are dealing summarily with cases of overcrowding in the prescribed plague area. Some 70 cases of offense in this direction were brought up at the Southern Police-Court of the city, and fines were imposed. There seems every hope that the outbreak is drawing to a close. The advent of colder weather may assist the sanitary authorities in their attempts to get rid of the disease, although climate and season have but little influence in the behavior of plague. In no other part of the British Isles is plague known to exist. The number of cases of bubonic plague has gradually decreased in Hong Kong; at present about one case daily is reported. The total number of plague cases since the beginning of the year has been 1,053, with 995 deaths.

CONTINENTAL EUROPE.

Typhus Among German Troops.—Typhus fever is raging in the Sixty-eighth Infantry at Coblenz, Germany, and also in the garrisons at Brunswick and Saarbrücken.

Royal Lady a Physician.—The only royal lady in Europe to hold the degree of M.D. is the consort of the King of Portugal. She was the Princess Amélie of Orleans, and was born at Orleans House, Twickenham.

Lady Physician for Female Prisoners.—The Berlin Chief of Police has appointed Fräulein Agnes Hacker, M.D., as medical officer for female prisoners. She is the first lady doctor appointed to such a position.

At the Thirteenth International Medical Congress in Paris, 4,000 members and delegates were present. Of this number 2,000 were Frenchmen, 750 Russians, 570 Germans, 350 Americans, 330 Italians, and 220 Spaniards.

"El Siglo Medico" announces that the Spanish government has appropriated \$8,000 to enlarge Dr. Cajal's laboratory at Madrid, with \$4,800 annually for its maintenance and a pension of \$1,600 for the distinguished scientist, on whom the Moscow prize was bestowed by the International Medical Congress.—[*Journal American Medical Association*]

The Military Step.—Dr. Colin, regimental physician in the French Army, has published the results of his investigations into the effects of regular marching in disciplined bodies upon soldiers. The regularity of the step causes the indefinite repetition of a shock of the bones and brain, infinitely more deleterious than an irregular walk, and to this regular repetition of the shock to the same parts of the body is due the peculiar aches, pains, and illness of troops. Dr. Colin's preventive is a rubber heel in all military boots. This heel has been tried at his instance in the French infantry, he says, and the result has been found to be a great relief to the soldiers.

MISCELLANY.

Leprosy.—There are 14 cases of leprosy on the Island of Guam. It is said that the disease is not increasing.

General Hospitals.—The Government of India has sanctioned the despatch of a third native general hospital of 500 beds, and the preparations at Calcutta of equipment for a fifth native general hospital of 500 beds.

The hospital ship "Maine" has arrived at Wei-Hai-Wei from Taku with many invalids on board, of whom 71 are Americans, including 2 officers.

Plague on British Vessel.—The British steamer *Highland Prince*, from Antwerp, August 30, London, September 7, and Bahai, October 4, arrived at Montevideo with plague on board. During the voyage 5 deaths occurred.

Obituary.—CLARK A. DUCKETT, of Great Yarmouth, September 30, aged 69.—ARTHUR HENRY LEETE, at Salcombe, September 21, aged 33.—HENRY SAVAGE, of London, October 3.—SAMUEL JAMES FLOOD, of the Royal Army Medical Corps, recently in Ireland.—JAMES DIXON BRADSHAW, of London, September 23, aged 52.

A Specific for Dysentery.—The Kafirs and Zulus of South Africa make use of the root of the geranium, in the treatment of dysentery. They simply chew the root, but the British army surgeons give it in the form of decoction in milk. The remedy is reported to be a real specific, no failure to cure within 36 or 48 hours being recorded.

Medical Reform in Ceylon.—In order to protect the natives of Ceylon from the magic treatment of their quacks or "medicine men," the Government has established hospitals throughout the island from which official distributions of quinin are made to the natives in the fever districts. The Government medical officers also make prescribing tours during which they frequently hold an outpatient department beneath a big banyan tree in order to accommodate the natives who come in large numbers for treatment.

Hospital for the Insane in Syria.—On one of the lower slopes of Mount Lebanon, Syria, near the road from Beyrout to Damascus, is a newly built hospital for the care of lunatics. Mr. Theophilus Waldmeier, a veteran missionary in Abyssinia and Syria, is the founder, and it consists of a central administration block and 2 pavilions, accommodating 20 of each sex. At present 17 patients are under care. Dr. Wolff, from the Munsterlingen Asylum, Switzerland, is the medical superintendent. This is the first organized lunatic hospital in Syria and it has in consequence attracted much attention, the need for such institutions in the East being great. It will probably be dependent upon support from Europe for a good many years. Dr. Percy Smith is the chairman of the committee in London.

South African Hospitals Commission.—The Hospitals Commission held its opening sitting at Kimberley on October 1. The doctors and the members of the hospital staffs, in giving their evidence, says the *British Medical Journal*, agreed that the hospitals in the town were well arranged and equipped, and that no complaints had been made. The evidence given by the men who took part in the fighting was exactly contrary. They complained of bad treatment at Paardeberg owing to the lack of administrative ability. The field hospitals there had been so badly placed that many men had to lie in pools of water. The camp at Maitland was placed in a similar position, the men lying in tents full of water, many of them without blankets, overcoats, or oilskins. Two deaths occurred in consequence. The men also complained of the food arrangements, and stated that the supplies were unsuitable for convalescents.

Plague and Cholera in India.—An increase in plague-mortality is reported throughout India. The chief rise is in Mysore State. In Bombay City the mortality has increased from 51 to 75, and in the province from 64 to 160, in one week. Cholera continues to prevail in Bombay City and a few other places, but it is decreasing among the troops. The total number since August 3 is 271 cases, with 165 deaths, while in Bombay City alone over 400 deaths occurred the last week of August, and over 100 were reported in Kashmir. Fresh plague regulations of a very modified form have been recently promulgated at Poona. They are apparently the result of the recent resolution of the Government of India on the report of the Plague Commission. There will be disinfection of houses in which plague has been found to exist, and also of adjoining houses. Free inoculation will be available at convenient hours and facilities will be given for inoculation at home. There is no evidence to show that the avoidance of active measures in Calcutta contributed to the outbreaks. On the contrary, Calcutta has suffered much less than other places have suffered.

1.—Bury opened a discussion on **Influenza as it affects the nervous system**, in the section of medicine of the British Medical Association. Cases in which the nervous system seems to be specially selected for attack by the bacilli and their poisonous products may be separated into 2 groups. 1. A group of nervous diseases which develop during or shortly after the febrile stage; such as meningitis and hemorrhagic encephalitis. 2. A group of nervous diseases which usually occur after the attack has subsided, such as neurasthenia and multiple neuritis. Of the nervous diseases belonging to the first group, 2 types of cases may be seen: (1) The comatose type; and (2) the delirious type. In the comatose type the patient gradually became drowsy and apathetic. Recovery may occur, but a fatal termination is more common. An examination of the brain in such a case may reveal nothing abnormal, or there may be congestion of its surface, or a purulent meningitis with or without an encephalitis, which is usually hemorrhagic in character. In the delirious type, restlessness, irritability, delirium, and even mania are the essential features. As a rule, affections of the cord appear to develop at a varying time after the attack of influenza; but, in rare cases, spinal symptoms show themselves during the attack and may constitute its salient features.

A greater variety of disorders of the nervous system may come after influenza than after any other disease. The cause of the postinfluenzal paralysis must be either functional disturbances by the influenza toxins or very slight changes in nerve-tissue, inflammatory or degenerative in character. Broadbent said that some of the effects of influenza on the nervous system are due to the action of the toxin. Other effects appeared to be directly due to the microorganisms. There are cases in which the results seem to be attributable rather to antecedent instability of the nervous system than to anything specific in the action of the influenza poison. The comatose form of attack seems to be due to the direct action of the microorganisms. Eide said that in his opinion the special nervous symptoms were due to absorption of the toxin secreted by the special germ of influenza, Pfeiffer's bacillus. This toxin exerts a selective affinity for different parts of the nervous centers, with a strong tendency to affect the medulla oblongata. In the spinal cord the sensory appear to be more markedly affected than the motor portions. Allbutt said that one of the clinical features that may, perhaps, be called decisive in relation to the diagnosis of postinfluenzal nervous diseases is the great suddenness of onset. The frontal lobes of the cerebrum are preferentially attacked. Pitt said that the great cardiac irregularity and failure not infrequently met with after an attack of influenza may be due to an affection of the cardiac ganglia and nerves quite as much as to a lesion of the muscle. MacCormac said that he believed that influenza was not a specific and distinct disease. It appears to him that influenza may cause throat, lung, gastrointestinal, or skin troubles by a disturbance of the nervous system through atmospheric influences. Mullick wished to emphasize the fact that there was too great a tendency to accept influenza as the primary cause of nerve-lesions. He was inclined to believe that many cases which were quoted as influenza were really due to syphilis, alcohol, or rheumatism, causes which had been revived by influenza toxins. Saundby said that he was a little surprised to hear influenza described by some speakers as a primary disease of the lungs or nervous system: an infectious process may localize itself in different organs. In postinfluenzal diabetes the pancreas will be found to be the organ involved. The interstitial pancreatitis, which is present in a considerable proportion of cases of diabetes, may be due to the action of the toxins of infectious disease. Ewart suggested that there might be a chronic influenzal intoxication due to microorganisms remaining lastingly in possession on the upper respiratory tract. In all patients, but particularly in those who had been subject to repeated attacks and who probably harbored the microorganism permanently, sanitation of the nasal cavities is an important indication. St. Clair Thomson said that cases of complete anosmia were not uncommon, and from the history of certain of these cases and from the absence of local lesions there could be little doubt but that influenza was the causative agent. Calwell drew attention to the importance of obtaining a history of recent influenza before the administration of anæsthetics, especially of chloroform. There have been a large number of deaths from chloroform administration, and this is especially the case during influenza epidemics. Buzzard said that the relative as well as the absolute number of grave diseases of the nervous system ascribable to toxemia had very largely increased during the last few years, and he was disposed to think that, although this increase was by no means to be attributed exclusively to the invasion of influenza, a large proportion must be credited to the direct influence of that disease. [JMS.]

2.—Payne opened a discussion on the **Problems of gastric ulcer** at the section of medicine of the British Medical Association. The following are the problems connected with gastric ulcer which seemed to the author most in need of elucidation: 1. Is gastric ulcer increasing in frequency? 2. Is the connection of hyperacidity with gastric ulcer proved; and can it be ascertained without danger? 3. Are our present means of diagnosis in nonfatal cases quite satisfactory, especially in cases where there has been no hæmatemesis, but even when this symptom has occurred? 4. Is there an acute form of gastric ulcer, different from the chronic form? 5. Is the original cause or starting point of gastric ulcer really known? 6. Is gastric ulcer so rare in the upper and middle classes as seems to be generally supposed? 7. During rectal feeding should taking water by

the mouth be prohibited? 8. Is acetonuria a frequent accompaniment of rectal feeding? Gordon said that a theory of microbic origin would explain the facts of gastric ulcer better than any other. When a gastric ulcer is excised it should be cut in half. One half should be hardened for cutting and staining, whilst the other should be immediately used for bacteriologic experiments. Caldwell emphasized the necessity of preventive treatment in gastric ulcer. The physician must be emphatic in his conduct of the case and, although the affection is apparently but a case of indigestion, if the patient is a young woman she should be put to bed, and an absolute milk diet insisted on. It is possible that some so-called perforations are really rents in the coats of the stomach due to adhesions. Cock reported a case in which there was simulation of gastric ulcer followed by perforation and subphrenic abscess. At autopsy pneumonia and pleurisy, with marked involvement of the diaphragmatic pleura in the inflammatory process, and adhesions between the diaphragm and the base of the lung was found, and no ulcer. She also reported a case in which, at laparotomy, no ulcer was found to have perforated. Stuart Low said that for some time he had been treating his cases of irritable stomach, painful digestion, and gastric ulcer with mucin, with most satisfactory and gratifying results. He used mucin in powder form that had been manufactured from animal bile. It is a dark brown powder, and almost tasteless and odorless and, therefore, quite unobjectionable to swallow. It should be given just before meals with an equal quantity (10 grains) of sodium bicarbonate. The good effects of this substance are markedly evident in the immediate alleviation of all painful sensations in the gastric region, and in the establishment of regularity in the action of the bowels. That the constipation is relieved is a most important fact, and the value of mucin as an aperient is a great point in its favor as a therapeutic agent, and of much interest physiologically. The diet in cases of gastric ulcer is also carefully regulated, such substances as calves' foot, mutton, and chicken jellies and thin cornflour with the frequent use of a pinch of freshly prepared marshmallow are allowed. The author feeds his patients regularly every 2 or 3 hours, according to the severity of the symptoms. The rationale of this method of treatment is to protect the irritable surface of the gastric mucous membrane, and especially the ulcerated part, from attrition by the food and constant worry by the hyperacid gastric juice; therefore, the mucin is given first to form a gluey coating over the lining membrane, and the surface is thus soothed and protected. If there is still any pain or uneasiness after nourishment then another dose of mucin and sodium bicarbonate is given, and the increased acidity is thus counteracted. The ulcerated surface of the stomach-wall is thus treated just as one on the surface of the body would be protected from friction and rested and given a chance to heal. [JMS]

3.—The studies of Cushny indicate that **intermittent pulse** may be divided into several classes, which can be diagnosed from each other tolerably readily: 1. True ventricular intermissions in which the pause is exactly equal to 2 pulse-intervals, and during which there is no cardiac sound. 2. True auricular intermissions in which the pause is shorter than 2 pulse-intervals, and during which there is no cardiac sound. This form is not infrequently seen in healthy persons, and appears to be due to excessive inhibition, for the phenomenon disappears on treatment with atropin, which paralyzes inhibitory nerves. In other cases it may be due to auricular disease. 3. False ventricular intermissions in which the pause is equal to 2 pulse intervals, but is often interrupted by a slight elevation. In every case a first heart-sound can be heard during the intermission. This form appears to be caused by excessive irritability of the ventricle leading to a premature systole. 4. False auricular intermissions in which the pause is shorter than 2 pulse-intervals. There is often a slight elevation of the pulse during the intermission, and the stethoscope reveals a systolic sound very soon after the last regular pulse elevation. 5. Another form of intermission has been described by Wenckebach, who attributes it to imperfect conduction of the impulse through the heart, perhaps especially in the auriculoventricular connecting fibers. [JMS]

5.—Wilson believes that the heart has the power of enlarging its chambers by means of a true muscular expansion

movement. In mitral regurgitation we have cardiographic evidence of increased **diastolic expansion of the ventricles**. In mitral stenosis cardiographic tracings show an accessory wave which the author calls the suction recoil wave. This is a small, sharp wave which occurs just after relaxation of the cardiac muscle has occurred. When relaxation commences there is still a strong stream of blood flowing into the ventricle. It is the impact of this stream upon the relaxed heart-wall that causes the small rise referred to. This suction recoil wave is closely associated with a diastolic cardiac sound which, in the author's opinion, is also due to the aspiratory power of the ventricle. This is the so-called reduplicated second sound which is heard at the apex in mitral stenosis. It might be called the third sound of the heart. It coincides exactly with the commencement of the suction recoil wave just spoken of. This sound is caused by the inrush of blood into the ventricle at the commencement of diastole. It is produced as follows: During the phase of diastolic expansion the auriculoventricular valve is kept more or less rigid by the rigidity of the heart-muscle. As soon, however, as relaxation sets in the valve is free to move, and if the auricle has not already been emptied by aspiration during the expansion movement, the in-rushing blood stream will flap the valve back against the wall of the ventricle in a manner calculated to produce the faint sound we are speaking of. The diastolic murmur of mitral stenosis is a suction murmur due to ventricular aspiration, and the fact that it is very often strong enough to give rise to a palpable thrill is evidence as to the force of the aspiration. If the diastolic expansion movement was purely a mechanical one it ought to be evident in aortic regurgitation as it is in mitral regurgitation. The cardiogram shows that this is not so. A marked feature of all the tracings taken by the author in aortic regurgitation is the absence of the diastolic expansion wave. [JMS]

6.—Gore concludes (1) that **gout** is not due to the presence of uric acid in the blood; (2) that the symptoms of gout are due to a toxin; (3) that the concurrent presence of uric acid is due to the action of the toxin on the liver; (4) that the toxin is formed by the action of one of the intestinal bacilli on an intestinal secretion specifically altered by diet, this alteration being assisted by hereditary disposition.

7.—Ewart and Percival have used **subcutaneous saline infusions** in cases of **pneumonia** with uncertain and exceedingly anxious though not hopeless prognosis. The histories of 6 cases are given. The authors conclude (1) that in the severe cases treated no unfavorable results were observed from the saline infusions; (2) that the infusions seemed to delay rather than to accelerate the fatal termination; (3) that they were not resented by the patients, and that in some instances they were acknowledged to be comforting; (4) that they were powerless to check the fatal course of the pneumonia in the worst type of cases; (5) that they do not seem, except in cases where only clear serum exuded from the cut surface of the gray hepatization, to have made any difference in the characteristic appearances of the pulmonary changes. While results have been disappointing, they do not suffice to prove that saline infusions are absolutely useless. A different composition, a larger bulk, or a greater frequency of administration might lead to very different results. The effects noticed were such as to recommend the method for a more extensive trial in cases with anxious prognosis. [JMS]

8.—Other things being taken into consideration, it is advisable to cure consumptive patients in the climate in which they will ultimately have to live. The **sanatorium treatment of consumption** is a minute and elaborate system made up of endless details, all of which are important. It is not enough to say, "Open all windows wide in all weathers, and all will be well;" it is not enough even to add, "Feed all patients very plentifully, put them through a process of superalimentation." With these two points, essential as they are, must be united careful regulation of exercise and rest and constant medical supervision. The qualities which most aid consumptives in recovery are: (1) strength; (2) wisdom; and (3) variability of temperament. Therefore, the essentials of the general treatment of phthisis are to preserve and strengthen the physique, to enforce prudence, and to induce placidity. In considering the length of time residence at a sanatorium is necessary, attention must be paid not only to the arrest of the disease, but to the permanent raising of the standard of the patient's health, in order that

recurrent attacks may be warded off. Walker thinks that the sanatorium treatment of consumption is, after all, a system of elaborated common sense, applied to a long and tedious illness, and for it to be a success all the factors which make up the convenient term hygiene must be introduced; a permanent supply of fresh air, a large quantity of nourishing and digestible food, carefully regulated exercise and rest, and the removal of all causes of worry and anxiety. The sanatorium treatment is capable of still further expansion; for example, children of tuberculous parents, whose physical resistance is presumably below par, might very usefully spend some time in a suitable sanatorium, from prophylactic considerations. There should be sanatoriums for children who are definitely tuberculous, and with these should be combined some arrangements for education for those who are able to avail themselves of them. The cure of tuberculosis in growing children is a far slower process than in people whose growth is completed. What are called, for brevity, "maternity sanatoria" might be formed with great advantage to the community. By this is meant sanatoriums where tuberculous pregnant women might be received for 3 or 4 months prior to their confinements, and in which they might remain for the necessary period afterwards. [J.M.S.]

9.—Davies, after a careful study of the question, concludes that the consanguinity is the chief factor in producing the high mortality from tuberculosis in the Isle of Man. [J.M.S.]

10.—Ewart reports the case of a groom, of 26 years, who was aphasic and paralyzed on the right side. A careful physical examination could detect no abnormality, thoracic, abdominal, or circulatory, except a systolic mitral murmur. The temperature oscillated between 101° in the evening and normal in the morning. The pulse ranged from 80 to 100, respirations from 24 to 34. There was a trace of albumin in the urine. A week after admission the general and the cardiac conditions became aggravated and he vomited. At this time the discovery of a changing and increasing murmur defined the case as one of **malignant endocarditis**. No improvement took place under treatment, although the patient seemed to be progressing fairly favorably; and his rather sudden death was unexpected. The state of the mouth was unusually bad. Besides stomatitis there was an exceedingly foul condition of numerous stumps. The fetor of the breath was intense and reminded one of the worst smell of decaying or macerating dead bone. Some of the hollow teeth contained plugs of offensive decomposing material. There were no glandular enlargements at the angle of the jaw. The case was diagnosed as one of **embolic hemiplegia** due to vegetations and ulceration or detachment of the aortic valve, with either vegetations upon the mitral valve or the condition producing Flint's murmur. Twenty cubic centimeters of antistreptococcus serum were given at the time of the aggravation of the symptoms, 6 to 10 cc. injections were given subsequently as well as one pint of saline infusion containing $\frac{1}{2}$ grains cacodylate of sodium. This injection was repeated 4 times. At autopsy a large, rough, grayish vegetation was found attached to the ventricular surface of the left posterior aortic cusp at the point of insertion where an ulcerative perforation had formed. Ragged vegetations also occurred on the right posterior cusp. The myocardium was free from disease. A large anemic infarct was found in the left kidney. In the cranial cavity an adherent decolorized clot was found in the left middle cerebral artery, about one inch from its origin. The tip of the temporosphenoidal lobe and the subcortical tissue of the island of Reil as far as the outer edge of the lenticular nucleus were softened. The latter softening extended in an anteroposterior direction for about $\frac{3}{4}$ inch in the tissue of the brain. [J.M.S.]

11.—In the discussion on the pathologic distribution of the diphtheria bacillus and the bacteriologic diagnosis of diphtheria at the section of pathology of the British Medical Association, the general opinion seems to be that there is nothing more certain than the fact that it is absolutely impossible to give a strictly scientific and certain diagnosis in a suspected case of diphtheria in 24 hours, and as the result of microscopic examination alone. The only thing that the physician has a right to expect is an opinion of a greater or less degree of probability. [J.M.S.]

12.—Muir reports a case characterized by hemorrhages from the mucous membranes and by purpuric eruptions,

intense anemia, marked deficiency in the amount of red bone marrow, and a deposit of iron containing pigment in the liver and in the kidneys. The patient was a boy, aged 14 years, who was suffering from nosebleed, vomiting of blood, with purpuric eruptions over his body and legs. A month before he had had a chill and suffered from a cough, with slight hemoptysis. On admission the patient showed marked anemia and there was evidence of a general oozing of blood from his gums. A slight general improvement resulted, and the purpuric eruption disappeared, but 7 weeks after his admission, the spots reappeared. On the following day, he vomited blood, and subsequently passed into a stupor, in which he died. The blood was examined about a week after his admission, when the red blood-corpuscles numbered 800,000, the hemoglobin was 11%, and the leukocytes equalled 7,000. The red blood-corpuscles showed little alteration beyond some variation in size and slight poikilocytosis; there were practically no megalocytes; and there were no nucleated red blood-corpuscles discoverable. There was a very marked diminution in the polymorphonuclear (neutrophile) leukocytes, which numbered only about 25% of the whole. The lymphocytes numbered about 70%, the rest being made up of hyalin cells. No eosinophile cells could be found. The blood plates appeared to be practically absent, a condition which has been observed in other cases of purpura. The urine contained no blood or albumin. The liver and the kidneys contained iron pigment. When the marrow of the femur was examined, instead of showing the red appearance usually found in anemic cases, it was found to consist almost exclusively of fat of whitish appearance. A similar condition was found in the ribs. When nassed into chloroform for purposes of embedding in paraffin, the marrow became dissolved, leaving scarcely a trace behind. In addition to showing this peculiar character, the marrow was deficient in quantity, the bone being distinctly thicker than normal, and also of unusually hard consistence. Microscopic examination showed that there was very widespread fatty degeneration in the various organs, heart, kidneys, liver, etc., and also in the small bloodvessels. The change seemed especially to affect the smaller arterioles, and was chiefly marked in the intima. The great mass of the marrow consisted of fat cells. Red blood corpuscles and the various forms of cells normally present were found in extremely small numbers. Only one or two nucleated red blood-corpuscles could be found after a very long search. The finely granular narrow cells were also extremely scanty, and of smaller size than usual. No eosinophile marrow cells could be found. In addition to the usual fat cells there were also some cells of indeterminate nature containing small globules, and there were also a few amorphous broken down cells. There was no evidence of pigment deposit in the bone marrow. The condition of the bone marrow was a primary change, or, to be more correct, did not occur secondarily to any of the other lesions noted. [J.M.S.]

13.—Williams thinks that **uterine myomas**, in a large proportion of cases, have their origin intimately associated with developmental irregularities; and conditions of this kind are probably the chief morphologic factors in their development. Many cases are cited from well known surgeons to substantiate this view. When Cohnheim first announced his theory of the origin of tumors from sequestered fragments of the germinating tissues, very few facts could be adduced to support it; but the light of modern science has shown that sequestered fragments of the various tissues and organs do exist in every part of the body that has been specially examined for them. The urogenital system is no exception to this rule, for the tract of the Wolffian and Mullerian ducts is strewn with debris of this kind. Long before Cohnheim's time the tendency of tumors to originate at the seats of development defects had been recognized by Paget, Virchow, and others; and as far back as 1853, Paget had remarked upon the weakness in resisting disease which belongs to parts congenitally abnormal. Recent observations show that most uterine myomas and cysts arise from dislocated myomatous elements connected with abnormally evolving "rests" of Wolffian and Mullerian structures, or even of the uterine mucosa itself. Thus their initial multiplicity may be accounted for, as well as the similitude of their structure to that of the uterine wall. [W.K.]

14.—Voelcker opened a discussion on the Pathology of cirrhosis of the liver in adults and young children

in the section of pathology of the British Medical Association. To ascertain what influence alcohol had as a cause of hobbled liver the author examined the records of 2,020 necropsies made at the Middlesex Hospital; of these, 149 were cases of cirrhosis of the liver, which was hobbled in 36. Of the 36 cases, alcoholism was acknowledged in 15, denied in 9, and not noted in 15. Of 4,278 necropsies made on children under 12 years of age at Great Ormond Street, there were 23 cases, and hobbled was present in 13. He concluded that alcohol played an important part in the production of cirrhosis, but in what way was uncertain. Large livers were rather more common in spirit drinkers than in beer drinkers, but the "gin-drinker's liver" could be produced by beer. Voelcker alluded to the effect of other poisons than alcohol in producing cirrhosis, and to the associated changes in the spleen, pancreas, and kidney. Hektoen wished to refer briefly to some recent demonstrations made in his laboratory on cirrhotic processes in the liver of animals directly induced by two different bacilli. The observations seemed to him to be of some interest in the suggestiveness of a somewhat similar course of events in some instances of human cirrhosis. One of the series of observations was produced by a bacillus belonging to the colon group, which was isolated from a guineapig that died spontaneously. The bacillus lost its virulence rapidly, and before sufficient experiments had been made to establish clearly the relation between the necrotic and proliferative changes in the liver. With early death, necrotic and degenerative changes only were found in the guineapig; in those animals that lived longer proliferation of connective tissue was associated with necrosis, and in other animals again cirrhosis entirely replaced the degenerative changes. The second series of observation concerned a bacillus that might be placed in the pseudodiphtheria group. It was isolated from the lesions of a case of blastomycetic dermatitis of the back of the hand. Inoculations in various ways with this bacillus and its products had been found to produce with a fair degree of consistency more or less necrosis and diffuse cirrhosis of the liver in guineapigs and other animals. Unfortunately this bacillus also lost its virulence before many of the experiments planned could be completed. Flexner's experiments include the inoculation of animals with poisons derived from bacteria, from the higher plants and other animals. The chief results were obtained with ricin and abrin and the blood-serum of the dog injected into the circulation of the rabbit. In these experiments it was shown that the primary effects of the poisons were exerted upon the liver-cells; necrosis was common. In the animals that died from acute poisoning, they were the principal and, excepting for a moderate leukocytic infiltration, the only important lesions. Where the animals survived some weeks, proliferative changes in the connective tissue, with the production of the so-called newly-formed bile-ducts, were met with. When the new growth of tissue came from the surface capsule, indentations were produced suggestive of the granulations of atrophic hepatic cirrhosis. While these results were suggestive of the part played by a primary degeneration and necrosis of the parenchyma they failed entirely to clear up the question, in that they did not exactly reproduce the morbid appearances seen in human hepatic cirrhosis. A study of the tissues from cirrhosis by ordinary staining, then after digestion of the sections with pancreatin, and lastly after staining for elastica by Weigert's method, show that not one only but all the connective tissues enumerated are increased or altered. The most surprising result is the great amount of elastic tissue in the perlobular new growth of connective tissue, and now for the first time to be found within the lobules. Flexner also called attention to the fact that death in chronic diseases, in most instances, is a bacterial affection and he emphasized the importance of such terminal infections. The chief microorganisms concerned are the pyogenic cocci. They may occur as causes of local infections. The portal of entry may or may not be discovered clinically or at the necropsy. It may be an angina, an old ulcer (as in the leg), or the result of a trifling surgical operation, as in paracentesis, or it may baffle every attempt to discover it, when we speak of the infection as cryptogenic. Lazarus-Bulow said that he believed that in the case of hepatic cirrhosis we have first a destruction of the hepatic cells themselves, be it as the result of the action on them of alcohol or some of

the bacterial poisons, and that subsequently an overgrowth of the normal fibrous tissue of the liver occurs to fill up a potential lacuna. A variety of hepatic fibrosis which affects children at an older age than is the case with intercellular fibrosis is often associated with great ascites and with a well-marked jaundice of a greenish hue, and considerable distention of the superficial abdominal veins. The view of R. Ileson seems to be in accordance with the facts. He suggests that this form of cirrhosis is really a late manifestation of congenital syphilis, not in the sense that it is a distinctly syphilitic lesion, but that the syphilitic poison when it acts upon the liver-cells of the fetus to a degree less than that which is necessary for the production of the typical syphilitic intercellular cirrhosis, damages them, and thus places the liver in an exceptionally vulnerable position. When, then, some factor arises that would be without effect upon the healthy liver, but which completes the injury commenced in intra-uterine life by the syphilitic poison, the way is laid open for the occurrence of that fibrous tissue hyperplasia which ultimately characterizes the hepatic condition. Barratt's observations, made in connection with Hailey, which were continued over lengthened periods of time, furnish a complete demonstration of the fact that simple ligation of a single bile-duct produces cirrhosis in the corresponding liver-areas. Lister reported a case of the association of an acute interstitial hepatitis with an acute diffuse hemorrhagic ulcerative catarrhal colitis of uncertain origin, which had caused death by hemorrhage and exhaustion. Fisher differed from the view that all cirrhoses originated as proliferation of interstitial tissue consequent upon degeneration of liver-cells, and thought that some might originate as an interstitial hepatitis. MacDonald referred to a case of cirrhosis of the liver in a girl with fatal hematemesis. [J.M.S.]

15.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 414.

16.—Eyre believes that the standardization of nutrient media by exact titration methods, using a really delicate indicator and accurately standardized neutralizing solutions, can alone be depended upon to give consistent and comparable results. [J.M.S.]

17.—**Lipoma of the kidney** is quite a rare condition and offers certain marked differences from ordinary lipomas, in the situation which it affects. As a rule lipomas are found in places where fat is normally present, but when they affect the kidney it is not in the region of the hilum they are found, but in the cortex, a part of the organ which is normally devoid of fat. The 2 specimens reported by Lazarus-Bulow were found at the postmortem and at first sight were thought to be secondary deposits. They were both about the size of a Spanish nut and were situated in the cortex immediately beneath the capsule. Although they were easily distinguished from the surrounding tissue they did not possess any distinct capsule. These tumors are only pathologic curiosities and do not have any clinical importance except possibly when they reach enormous size, as in a case reported by Warthin, in which a lipoma weighing 2 pounds was recognized and removed during life. [G.B.W.]

18.—Though the **Argyll Robertson pupil** is chiefly seen in locomotor ataxia and general paralysis, it may be found in many other diseases. It should be looked upon as an almost certain sign of antecedent syphilis, either congenital or acquired. Harris has seen it in juvenile locomotor ataxia and general paralysis with marked evidence of congenital syphilis, in progressive muscular atrophy, in lead-poisoning, aortic aneurysm, hemiplegia, syphilitic meningitis, ataxic paraplegia, nuclear ophthalmoplegia, choroiditis, and in numerous instances in patients who presented themselves for all manner of symptoms, but showing no signs of ataxia or anesthesia, and with normal or even brisk knee-jerks, but in almost every instance with a clear history of syphilis. It seems most probable, in the absence of direct pathologic evidence, that the Argyll Robertson pupil is due to sclerosis of the nondecussating Meyner's fibers, on one or both sides, according as the loss of light reaction is unilateral or bilateral, rather than due to any nuclear degeneration. [G.B.W.]

2.—See PHILADELPHIA MEDICAL JOURNAL, Oct. 13, p. 675.

3.—Lyle defines **puerperal sepsis** as nothing more or less than a surgical fever arising from the infection of a wound, the only differences being: (1) the large extent of surface liable to infection; (2) the structures involved; (3) the presence of a quantity of dead material which easily lends itself to infection; and (4) the fact that the patient is undergoing certain physiologic changes, this, perhaps, making her more liable to infection. The varieties of puerperal sepsis are: 1. **Sepremia**, or septic intoxication due to acute sepsis and which includes fetid sapremia due to the absorption of the products of decomposition in the parturient canal; suppurative, due to the absorption of toxins produced by suppuration on the surface of the parturient canal; and inflammatory, due to an acute inflammation of the vagina, uterus or parametrium. 2. **Septicemia**, otherwise known as an acute septic infection which is extremely fatal but comparatively rare, and may arise independently or as a consequence of any of the preceding conditions. 3. **Pyemia**, which is due to the absorption of a septic thrombus in one of the uterine sinuses into the blood-stream by means of the veins. Lyle says that it is well to remember that any obstetric operation, even the making of a vaginal examination, is similar to a surgical operation, and the sources of infection are exactly similar. There are a few rules which he thinks would, if strictly observed, materially lessen the prevalence of puerperal sepsis. 1. The thorough disinfection of the patient's external genitals and the hands and forearms of the medical attendant and the nurse, prior even to a vaginal examination. 2. The abolition of routine antepartum and postpartum douchings, which are often both unnecessary and dangerous. Corrosive sublimate solution is especially condemned as having many disadvantages from which creolin and carbolic acid solutions (half an ounce to a gallon) are free; and it has no advantage; for it is the quantity of the douche which is important, since it is not a question of destroying the bacteria in the uterus, but of washing away the bacteria out of the uterus. 3. All instruments used during an obstetric operation should be aseptic, and when not in use should be kept in aseptic cases. 4. The proper conduct of the third stage of labor. 5. The strict limitation of vaginal examinations. 6. The disuse of all so-called "aseptic lubricants," since they are unnecessary and may form good culture-media for bacteria. 7. The immediate suturing of all perineal lacerations, not only for the sake of the patient's comfort in after life, but also to diminish the extent of the surface liable to infection. [W. K.]

5.—Macgregor describes a form of anemia which is not uncommon in children, and which he believes is never met with in the adult. The anemia is accompanied by enlargement of the lymph nodes. Differential count of the leukocytes showed 12 to 13% lymphocytes, 20 to 39% large mononuclears, 41 to 63% polymorphonuclears, and 1 and 2 to 7% eosinophiles. The condition is called **lymphatic anemia** by the author. [J. M. S.]

6.—Poynton and Paine have studied the **etiology of rheumatic fever**. They have demonstrated diplococci in

8 successive cases of acute rheumatism. These organisms have been present in 5 cases in pure culture. They have obtained them (a) from the blood of living patients suffering from acute rheumatic pericarditis; (b) from the pericardial fluid and from the fragments of granulations removed from the valves after death; and (c) from the throat of the living patient suffering from rheumatic tonsillitis. They have isolated them and grown them in an acid medium and also upon blood agar. The organisms have also grown in the pericardial fluid, which was proved on those occasions to be acid. They have been isolated in pure culture from the joint exudation, heart blood, urine from the bladder, and cerebrospinal fluid of rabbits that have been inoculated with a sufficient dosage. They have been demonstrated in the cardiac valves, pericardium, and tonsils, and in a nodule in fatal cases of rheumatism. They have been demonstrated in the cardiac valves, pericardium, joint exudation, kidneys, liver, connective tissues, pleura, cerebrospinal fluid, lungs, and urine of rabbits inoculated intravenously. When inoculated intravenously into rabbits they produce a polyarthritis, bursitis, and tenosynovitis. This polyarthritis may completely disappear. In some of the joints that have been affected for a considerable time the fluid is opaque and contains fibrin, endothelial cells, mononuclear and polymorphonuclear leukocytes. In other joints the exudation is clear. In one case they produced a paresis of the lower extremities which passed off in about 3 weeks. They produce multiple valvulitis and pericarditis, both nonsuppurative. They produce in the liver and kidneys a condition of coagulation necrosis. This in the case of the kidneys chiefly occurs in the convoluted tubules. They produce plastic pleurisy and pneumonia. The urine is acid and loaded with urates. They have not produced suppurative foci in the viscera. They produce a condition of fatty degeneration and destruction of the muscle fiber in the myocardium analogous to that found in the human heart as a result of severe rheumatic carditis. The clinical symptoms are characterized by multiple painful joint swellings, wasting, with (in the less severe cases) a maintenance of the appetite. There is moderate pyrexia. The heart is affected early; tachycardia, dyspnea, and irregularity of cardiac action, together with valvular murmurs, pericardial and pleural friction, have all been observed. The clinical symptoms are, on the whole, remarkably constant when the organism is passed from animal to animal, though the tendency is for increase in the severity of the cardiac lesions and diminution in the arthritis. The organisms occur as minute cocci associated in pairs; in liquid media they grow in chains of varying length; while in solid media they grow in masses that resemble the arrangement of staphylococci. They grow both aerobically and anaerobically. They may be cultivated upon ordinary media, but do not thrive and rapidly lose both their virulence and their characteristic appearances. There can be but little doubt that these diplococci are identical with those discovered by Triboulet in 1897 and by Wassermann in 1899. The resemblance between the disease produced in rabbits and the rheumatic fever of man is a very striking one. The valves of the heart are attacked from within and the diplococci are not at first found upon the surface. When the connective-tissue proliferation that they produce in the valve becomes a granulation and breaks down, they may be found on the surface. The discovery of the diplococci in the rheumatic nodule is of especial interest, for this lesion above all is looked upon as highly characteristic of rheumatic fever. The organism has been found in the kidneys of rabbits after death, especially in the convoluted tubules where they lie in the cells and where they produce coagulation necrosis. Their presence is associated with a urine which is acid, which contains granular casts, and which is loaded with urates. They have been isolated and cultivated from the urine in the bladder of rabbits. In the rabbit the authors have found areas of coagulation necrosis in the liver. The liver-cells undergo a rapid destruction and the microorganisms can be demonstrated within them. They occur, sometimes in vast numbers, in the joint exudation in the rabbit. In the lungs and pleura of one of the rabbits that had been killed when suffering from pericarditis, valvulitis, pleuritis, and pneumonia, diplococci were demonstrated, which are believed to be identical with those found in the other viscera. In one case both tonsils were found enlarged after death and inflamed, and this when the illness had been of long duration.

In a film from the deeper part of these tonsils the authors found diplococci, and diplococci were also present in the sections that were made of the tonsils. Diplococci were isolated from the throat of an adult, the subject of rheumatic fever, who was suffering from an acute faucial catarrh. In the case of a rabbit that died from severe valvulitis the diplococcus was isolated in pure culture from the fluid in the lateral ventricles. In a case of chorea numerous diplococci were demonstrated in the perivascular lymph-spaces of the pia mater, in its capillaries, and also in some parts of the motor area of the brain. In another case of chorea of similar type they were demonstrated in large number in the mitral valve. The term "infective endocarditis," which has for some time been under suspicion, can no longer be used in contradistinction to "rheumatic endocarditis," for both are plainly infective. [J.M.S.]

7.—In the determination of chloroform the true objective at which to aim is the measurement of CHCl_3 by means of its chlorin. Edmunds describes a method by which the chlorin is promptly and easily reducible to the saline form and made to serve as the measure of its chloroform. The weight of the chlorin being accurately determined multiplication by the factor 1.12314 gives the weight of the chloroform. A solution of permanganic acid and potash in excess with potassium permanganate, potassium hydrate, and water is employed in the process. [J.M.S.]

8.—Overend gives the calorie-values of certain artificial infant foods. [J.M.S.]

9.—A girl 6½ years old swallowed a half-penny, which was successfully removed from the level of the second dorsal vertebra by means of a flexible wire covered with gutta-percha. [M.B.T.]

10.—A boy of 13 twisted his right ankle while bowling at cricket. Probable rupture of the anterior annular ligament resulted, which was successfully treated by strapping and bandaging. [M.B.T.]

11.—Turney reports the case of a girl, aged 15 years, who died of typhoid septicemia. Serum diagnosis was positive during life. At the necropsy the alimentary canal was normal from the fauces to the rectum. The *Bacillus typhosus* was isolated from the splenic pulp. [J.M.S.]

12.—Four cases of acute ileocecal intussusception are reported which were treated by celiotomy with reduction or excision. A male child, 8 months old, had an ileocecal intussusception reaching nearly to the anal canal, of 2 days' duration. Blood and mucus had been passed. There was vomiting, tenesmus, and a tumor was felt. The abdomen was opened, the intussusception reduced, and a loose meso-appendix was sutured to the mesentery to assist in preventing a recurrence. Recovery resulted. In a second case a male child, 7 months old, had ileocecal intussusception reaching to the splenic flexure, and also a double enteric intussusception about 18 inches from the cecum. The symptoms had lasted about 12 hours. A little blood was passed, there was no vomiting, tenesmus and a tumor were felt. Celiotomy was performed and reduction effected. A good recovery resulted. In a third case a boy, 7 weeks old, had had symptoms of ileocecal intussusception for 5 days. There was vomiting, passage of blood, and a tumor, which was palpated with difficulty. On opening the abdomen a rupture of the colon and peritonitis was found. Excision of the intussusception with end-to-end anastomosis by Murphy's button was performed. Death resulted from shock 9 hours after the operation. In a fourth case a girl, 5 months old, had been suffering with symptoms of ileocecal intussusception for 2½ days. There was vomiting, passage of blood and mucus, and a tumor. Celiotomy was performed and reduction effected, but death resulted 30 hours later.

13.—An Indian soldier, 28 years of age, had been suffering for some time with pain in the right loin, radiating into the groin. As there was no improvement under treatment, nephrolithotomy was performed. At the first operation no stone was found, and at a second operation nothing could be felt, but on needling the kidney, a stone was located at the seventh puncture, and a calculus was removed which weighed 36 grains. Uneventful recovery followed. In a second case a man, 35 years of age, gave a history of renal colic and pain. Nephrotomy was performed and several small cysts were opened, but no stone was located. During convalescence the patient had to be placed in a ward containing many famine-stricken patients with sloughing ulcers, and

erysipelas got into his wound, nearly killing him. Recovery eventually resulted. [M.B.T.]

1.—Ranney gives certain axioms relating to the modern methods of diagnosis and treatment of eyestrain, the gist of which is as follows: Correct accurately all errors of refraction both for distant and near points, for this a mydriatic is, in all but the very rarest of cases, necessary. Astigmatism should be detected by the ophthalmometer of Javal and by cylindric trial lenses. Neither retinoscopy, trial lenses, nor the ophthalmoscope are positive in estimating "latent" refractive errors, but the former is the best in skilful hands. Cylindric glasses should preferably be set in spectacle frames. All glasses should be inspected by the oculist before being worn by the patient, and decentered lenses should be carefully guarded against. Patients should be instructed as to decentering of their glasses from bending and should also be taught to test their eyes from time to time for any change in the refraction of an eye. All tests for muscular disorders should be made after the errors of refraction have been corrected. The "manifest" muscular errors are only of much value when acting as pointers in the search for some latent heterophoria. The most positive and uniform standard of power in any of the ocular muscles is the normal power of abduction. Whenever the abduction falls below 8°, latent esophoria may safely be suspected; whenever it exceeds 8° exophoria is apt to be present. A marked difference in the power of sursumduction on the 2 eyes is always to be regarded as a suspicious sign of hyperphoria. Manifest or latent anomalies of the vertical muscles should as a rule be rectified before coexisting anomalies of the lateral muscles are treated. Operative procedures upon the eye-muscles should never be too hastily performed. [O.B.W.]

2.—Vaughan says that during the past year 4 cases of papillitis have come under his observation, but in only 2 instances was the inflammation of the optic nerve ending due to syphilitic changes within the cranium. He believes that the optic nerve can become involved in syphilis in 3 different ways. First, from the direct action of the specific poison upon the nerve fibers themselves, thus producing a primary syphilitic inflammation; secondly, from a syphilitic growth—either a gumma or a syphilitic meningitis—within the cranium, thus producing an increased intracranial pressure, with its resulting papillitis or papilloretinitis, or direct extension of inflammation in case of meningitis; and thirdly, from diseased conditions of the bloodvessels in the cerebrum, optic nerve, and retina, produced by syphilis. In his 5 remaining cases the retina alone was involved in 3, and both the retina and choroid in 2. [G.B.W.]

3.—Floersheim has found that when the heart has been irregular in its rhythm, with lessened force and quality of the sounds, in many cases, suprarenal capsule has caused the heart to become more regular in its action, the force quite markedly increased, and the pulse more forcible in character. In some cases a slight increase in the number of pulse-beats has been noted; whilst in other cases no change resulted or there was a slight fall or decrease. The heart seems to be markedly toned up in many cases treated. When the heart's action is full, bounding, and regular in rhythm, no appreciable effect was noticed. When the heart is flaccid, the pulse weak, the apex beat diffused, the action of the

heart fluttering and irregular, we find the most marked and beneficial effects of the drug. After the immediate stimulating effects of the drug have passed off, the heart seems to be left in better condition than it was before the administration of the remedy. Sometimes supranal causes the intermittent character of the heart's action to disappear. Supranal extract acts in from 10 seconds to 10 minutes. [J.M.S.]

4.—By combined electrization or galvanofaradization is meant the simultaneous application through the same electrodes of the 2 forms of dynamic electricity, galvanic and the faradic currents. The application of both forms has been made by Rockwell in cases of urethral spasm, spasm of the pharynx, facial spasm, exophthalmic goiter, and paralysis of the diaphragm with satisfactory results. The combination of mechanic and chemic effects stimulated the phrenic nerve in the latter case far more powerfully than either current alone would have done. [J.M.S.]

5.—Foster reports 3 cases of Mules's operation, which consists in the insertion of a glass globe into the eye-ball after an exenteration had been done. The result in these cases were all good, though in the first there was not as much motion to the artificial eye as had been hoped for. The great advantage of Mules's operation is that the glass ball within the sclera maintains the muscular apparatus of the eye in nearly its normal position, and so secures its better action, which results in better motility of an artificial eye when properly fitted. Also it is probable that in children the development of the orbit is maintained by the presence of the rounded globe in its cavity. The most serious objection is the prolonged convalescence, which lasts from 10 to 15 days, about double the length of that following enucleation. Sometimes the glass ball is discharged, due either to suppuration, the insertion of too large a ball, or to the early absorption of catgut sutures. The operation is especially adapted as a substitute for enucleation in children. [G.B.W.]

6.—The case reported by Thrasher was that of a woman of 56, who had been for some time suffering from increasing hoarseness, with gradually developing dyspnea. On laryngeal examination a growth was found occupying the posterior and lateral walls of the larynx. A piece of the growth was removed, and under the microscope proved to be a fibroma. As beginning cyanosis was present when the patient was seen for the second time, immediate operation was deemed necessary. After a preliminary tracheotomy, the larynx was opened, and from the lower border of the cricoid to above the vocal cords the mucous membrane of the larynx was found pushed into the lumen of the larynx, causing it to present a flattened instead of the normal concave surface. There were no especial circumscribed growths. By means of cutting forceps and curets, enough of the fibrous tissue was removed to allow of easy breathing. In removing the tissue no thought was taken as regards the position of the vocal cords. The inner surface was cauterized with a saturated solution of trichloroacetic acid, iodoform dusted on and the larynx brought together with silver wire sutures. After a period of less than a month the tube was dispensed with, the laryngeal opening being quite sufficient for all breathing requirements. The final result was most satisfactory, the patient being able not only to breathe comfortably, but also to speak, though in a somewhat husky voice. [G.B.W.]

7.—In this case the pin had been lodged in the larynx for 2 years, causing continued suff'ring and ever increasing ill-health. After considerable difficulty the position of the pin was made out by laryngoscopic examination and was seen to have passed directly through the right arytenoid eminence with the sharp point and about $\frac{1}{2}$ of its length emerging from the posterior aspect of the larynx. Attempts at removal without general anesthesia failed because of restlessness of the patient. The child was therefore anesthetized and after considerable difficulty the pin was extracted by the combined use of forceps and finger. The recovery was prompt though the external induration did not disappear for 3 months. [G.B.W.]

October 13, 1900. [Vol. lxxii, No. 15.]

1. Hypertrophy of the Turbinate Bodies, and Their Relations to Inflammation of the Middle Ear, With a Report of Fifteen Hundred Operations. CHRISTIAN R. HOLMES.
2. Dilation of the Colon. H. G. MARX-MILLER.

3. On the Employment of the Upright Position in Ether-Operations Upon the Nose, Throat, and Ear. THOMAS R. FRENCH.

5. The Future of Specialties. CHARLES B. KELSEY.
6. The Etiology of Pulmonary Tuberculosis, Its Course and Termination. S. A. KNOPF.

1.—Holmes continues his article on **hypertrophy of the turbinated bodies**, and says that Seneff has proved that the direction of the air-current is not changed by the total absence of the middle and inferior turbinates. Further, he calls attention to the importance of attending to nasal and pharyngeal conditions, in cases of middle-ear disease; especially does he lay stress on the fact that the adenoids, hypertrophies of the turbinated bodies, polypi, etc., must be removed if normal conditions are to be obtained. [G.B.W.]

2.—Marxmiller reports a case of **dilation of the colon** in a machinist, aged 52 years, which he believes is due to a tertiary syphilitic lesion of the spinal cord. [J.M.S.]

3.—French says that the idea of danger following **etherization in the upright position** is not based on the proper comprehension of the conditions present. He says that even in deep narcosis, if reasonable care is taken to prevent the blood from flowing over the arytenoid structures, the danger of pneumonia or bronchitis from inspiration of the blood or secretions is very slight. He has devised a chair, built of bicycle tubing and furnished with fixtures for securing the patient thereto, which greatly facilitates etherizing the patient in a sitting posture. The advantages of the upright position for ether-operations upon the nose, throat, and ear, may be summed up as follows: (1) The very considerable reduction in the amount of blood lost; (2) the reduction of the chances of ear-complications, by securing complete drainage of the nasopharynx of blood; (3) the ease, thoroughness, and accuracy with which operations can be done in the shortest time, by the retention of the usual relationship between operator and patient. [G.B.W.]

Medical Record.

October 8, 1900. [Vol. 58, No. 14.]

1. Medullary Narcosis During Labor. S. MARX.
2. Observations on Subclavian Deligation. SCHUYLER COLFAX GRAVES.
3. Tuberculosis and Its Treatment. MARGARET STANTON.
4. Appendicitis Larvata and Inflammation of the Right Broad Ligament, Tube, and Ovary. OTTO THIENHAUS.

1.—It is of interest to note that **medullary narcosis** is not a new method. The prior claim to the operation must in all justice and honor be given to J. Leonard Carning, who, in 1885, made original practical experiments and published a number of papers describing his work. Marx has used medullary narcosis in 30 cases of labor and gives in detail the history of 23 of these, and fully describes the technic of his method. In his experience there has never appeared any symptom to make him apprehensive of either immediate or remote danger. All the patients made ideal convalescences, and all the children alive before delivery were born alive and well, although many difficult and trying labors were encountered. Explorations, versions, extractions, placental removals were readily done, and he never noticed any greater disposition to bleed than in an ordinary case. Asepsis of person, of instruments, of patient and of the solution must be as carefully attended to as if the abdomen were about to be opened. The operation should be done only by one trained in surgical asepsis. He has found eucain valueless and uses cocaine, the solution of which must be freshly prepared and the injection made between the fifth lumbar and first sacral vertebra. The anesthesia lasts from 1 to 5 hours. He has carried a woman by repeated injections for 8 hours through her labor with practically no pain and considers it a method ideally suited to mitigate or absolutely allay the dreadful pains of a normal labor, with no danger to the mother and none to the child, immediate or remote. [W.K.]

2.—Graves proposes substituting for a guide in the ligation of the subclavian artery the cord of the brachial plexus of nerves for the scalenus anticus muscle instead of exposing the deep-lying muscle and feeling in front of it, the more easily located brachial cord is exposed and the finger placed behind it. His attention was called to this by an operation of this kind which he performed, and since then he has made a number of dissections to determine this point. [M.B.T.]

3.—The article is a plea for greater care in the **treatment of tuberculosis**, and for the provision of more satisfactory means for the treatment of the poor in proper sanatoriums. Among other points in the treatment of cases of tuberculosis, Stanton states that she has been able to persuade patients to take milk with eggs in it, or other fluids, after meals, when the appetite has already been satiated, while solids could not have been taken. This does not, in her experience, upset the appetite for the next meal, but does aid in getting much more nourishment into the patient. [D.L.E.]

4.—The term **appendicitis larvata** was introduced by Ewald in 1889, and by it is understood appendicitis of a chronic, insidious character which moves softly without developing into a real acute attack. Thienhaus reports 3 cases, and as an aid to diagnosis of this chronic condition thus summarizes the symptoms: Disturbances in the intestinal tract, flatulent colic, abdominal pain of more or less intermittent nature, located by the patient sometimes in the right, sometimes in the left iliac region, extending in some cases to the navel, epigastrium, or right hypochondrium. These disturbances are associated sometimes with headaches, dysmenorrhea combined with menorrhagia, and more or less increasing cachexia; slight attacks of fever occur in some cases. On physical examination slight, ill defined tenderness is found at McBurney's point, about the navel, sometimes in the left side or in the neighborhood of the liver. On bimanual palpation, through either the vagina or the rectum, the uterus is found to be in dextroposition or dextrorotated or flexed, the right broad ligament shortened and retracted; the right tube and ovary more or less in a state of inflammation. Concerning the treatment of appendicitis larvata, it must be recognized that only operative measures can be taken into consideration. They are indicated because (1) there is no other means of correcting existing pathologic conditions, and (2) the patient is in constant danger of an attack of appendicitis, followed by peritonitis. This radical treatment is especially necessary in case of patients with whom subsequent pregnancy is probable, since appendicitis in combination with pregnancy gives the most serious prognosis for both the fetus and the mother. [W.K.]

1.—Marcus says J. Leonard Corning, of New York, in 1885, is the first gentleman to record spinal anesthesia; he reports his experiments tried on a dog and the human subject. In this his first report he claims that it is unnecessary to inject the medication into the spinal canal, stating "that in the human subject numerous small veins (vena spinosa) run down between the spinous processes of the vertebra, and, entering the spinal canal, join the more considerable vessels of the plexus spinalis interna;" that by this arrangement of the circulation the cocainezation of the cord would be obtained. The record of his experiments is as follows: 1. He injected 20 minims of a 2% solution of cocain into the space situated between the spinous processes of 2 of the inferior dorsal vertebra. Five minutes after the dog had been injected he noticed incoordination of the lower extremities. A short time after, on testing with the faradic current he noticed anesthesia of the region supplied by the cord below his point of injection. Four hours later the animal had entirely recovered. In Experiment 2 he injected in a human subject, between the spinous processes of the eleventh

and twelfth dorsal vertebra, 30 minims of a 3% solution of cocain. After the lapse of 6 or 8 minutes, having obtained no results, he injected a similar quantity into the same place. Ten minutes later the subject complained that his legs "felt sleepy." Sensibility was impaired when tested by the electrical current. The impairment "was principally limited to the lower extremities—the lumbar regions, the penis, and the scrotum." When standing the subject complained of dizziness; the ability to distinguish differences in pressure seemed to be well preserved. He was able to pass a sound almost unnoticed, though this was usually accompanied by considerable pain. The pupils were slightly dilated. The constitutional symptoms noted were headache, slight vertigo, but no nausea. The subject experienced tingling sensations and numbness of his lower extremities until night, also dryness of the throat and mouth accompanied with mental exhilaration, probably due to the amount of cocain injected. The utility of this method so impressed Corning that he continued his experiments and widened its field of application in neurology, reporting his results in 1888. It is in his work on "Pain," that he records the definite results, for which I believe he should receive the credit of being the first to try medullary narcosis for therapeutic purposes; and by his results of anesthesia opened up the field for the possibilities of operating in or upon the analgesic areas. Five years elapsed after the last article of Corning, when the attention of the world was again called to this form of anesthesia by A. Ber, in 1899, in his original monograph. He experimented with it, and was able to obtain anesthesia sufficient to do any operation on the lower extremities. The first report of its use in obstetrics was made by O. Kreis in the *Centralblatt für Gynäkologie*, July 14, 1900. [A.B.C.]

2.—Brooks gives a general review of the modern teaching concerning the treatment of tuberculosis, especially recommending sanatorium treatment. [D.L.E.]

4.—Kime reports 3 cases of lupus which he treated by condensed light rays with success. He states that 5 other cases now under treatment are improving. Ordinary lupus requires from 4 to 20 weeks for successful treatment. In order to demonstrate the extent to which rays of the sun penetrate he publishes 2 photographs, one of which was taken through the chest of a well-developed man, and the other through the right hand of the writer. [D.L.E.]

Medical News.

October 6, 1900. [Vol. lxvii, No. 14.]

1. Internal Secretion of the Ovary. ARTHUR W. JOHNSTONE.
2. Internal Antisepsis. REYNOLD WEBB WILCOX.
3. The Treatment of Consumption at Home. JOSEPH EICHBERG.
4. Iritis. J. H. MCCASSY.
5. Neuralgia Paresthetica. JAMES J. WALSH.

1.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 995.

2.—Wilcox, after stating his belief in the future of **internal antisepsis** in internal diseases, discusses those in which it has been used with good results, particularly typhoid fever, in which chlorin is of great value; tuberculosis, in which creasote has proved of advantage; and those conditions of the elementary tract in which naphthol and similar drugs have diminished the activity of the process. Antiseptics may, however, be injurious, and are not to be preferred to surgical intervention, if the focus can be reached by this means. Among the few internal antiseptics, in addition to those mentioned, are the salicylates, silver, quinin, etc. The best form in which silver can be used, is the preparation of Credé. Wilcox believes that tribromo-phenolate of bismuth is a valuable drug in cases of intestinal infection. The most valuable urine antiseptic is hexamethylen tetramine. [J.S.]

3.—Eichberg divides the **treatment of consumption** into 4 parts: the specific, the climatic, the dietetic, and the hygienic. There is no specific as yet discovered. As the great majority of consumptives are unable, for financial or social reasons, to leave their homes, climatic treatment is only applicable for the few. In this climate the patient should spend almost the entire 24 hours out of doors, even sleeping out of doors in the summer time. Food should be

abundant in quantity, and nourishing in quality, an effort being made to secure excessive assimilation. The patient should rest almost constantly, and all the surroundings should be as cheerful as possible. Drugs should be used to meet special indications, such as night-sweats, cough, etc. The patient should be encouraged, if improving, to take his temperature, and to weigh himself at stated intervals. [J.S.]

4.—M. Cassy runs over the subject of iritis in a general way, touching on the etiology, symptomatology, pathology, diagnosis, and treatment. [G.B.W.]

5.—Walsh reports a case of *meralgia parasthetica* occurring in a Polish Jew, 45 years of age. The symptoms were: an oval patch, 5 by 3 inches, on the outer side of the right thigh, in which the patient had painful or hot sensations, and which was almost anesthetic; in a corresponding area on the left leg there was slight hyperesthesia; the pain was always relieved by rest; it was always worse just before a rainstorm. He was neurotic; the kneejerks were slightly exaggerated, and there was some chronic gastrointestinal disturbances. Walsh considers the treatment hopeless. [Our own experience has been that nearly all cases can be relieved, and some cured by suitable measures. Operation is a last, but promising, resource in severe cases. J.S.]

1. Cocain Anesthesia by Lumbar Puncture. Two Cases of Hysterectomy. J. RUDLE GOFFE.
2. A Consideration of Finger Infection, With Special Reference to the Joints and Tendons. ELLSWORTH ELIOT.
3. The Prevention and Treatment of "Colds." W. SCHEPPENEGRELL.
4. Treatment of Rheumatism and Some Phases of Indigestion; Gouty Diathesis. CHARLES E. PAGE.

1.—The success which has attended the **intraspinal injection of cocain** for the purpose of producing analgesia of lower part of the body led Goffe to use it in a case of abdominal hysterectomy which he believes is the first instance of the kind on record. The patient was a woman of 51, suffering from hemorrhages due to multiple fibroids. One-third of a grain of cocain was injected in the third lumbar space; but as the analgesia was imperfect, 15 minutes later the needle was inserted in the second lumbar space, 22 drops of spinal fluid were allowed to escape and $\frac{1}{2}$ of a grain injected. Analgesia promptly appeared, reaching above the umbilicus. The operation occupied 40 minutes and the recovery from the cocain came so promptly that the last manipulations, the removal of sponges from the abdominal cavity and sewing of the wound, gave occasional twinges of pain. There was some nausea, vomiting, and headache afterward, the vomiting recurring on the second day. Aside from this the recovery was uneventful. Goffe says that what remote consequences may develop as the result of such interference with the spinal fluid as this method involves, can only be determined after more prolonged observation; but up to the present time no detriment to patient has attended the procedure, although observations have extended over a period of 2 years. [W.K.]

2.—Eliot says that the **infections of the finger** vary greatly in their severity from a superficial suppuration just beneath the skin to an extensive necrosis involving the deeper structures. The palmar surface of the finger is much more frequently involved than the dorsal. One of the more serious conditions is the involvement of one or more joints, which may take place either as the result of the introduction of the agents of infection through a wound penetrating the joint, or the germ may be carried from the original focus by a lymphatic vessel directly into the joint-cavity. Pathologic changes resulting from joint-infection may be divided into (1) the stage of joint distention; (2) the stage of joint-disintegration, and (3) the stage of repair. The advent of the third stage depends on the freedom of joint-drainage. The destructive process of the joint, consists essentially in necrosis of the end of the bone, and destruction of the capsular ligament. When the lateral ligament gives way there is preternatural mobility, which may be elicited usually without pain, and furnishes a pathognomonic symptom. The ultimate result may be either a fibrous ankylosis or in favorable cases the formation of a new capsular ligament enclosing a pseudoarthritic cavity. Treatment should consist in

the application of suitable dressings to the part, which should be elevated and put in absolute rest, and in the use of incisions which allow generous drainage, and thereby prevent the retention of any foul material in the area of inflammation. Eliot closes his article by reporting in detail four cases. [G.B.W.]

3.—Scheppegrell believes that overheated rooms and very warm clothing are more frequently responsible for coryza than exposure to low temperature. In order to guard against this disease, it is important that the nose should be normal and that nasal breathing exist. Of the various drugs commonly used, some, such as quinin, are of but little value, and others, such as cocain, are distinctly injurious. Perhaps the best treatment is douching the nose with a $\frac{1}{2}$ % saline solution. [J.S.]

4.—Page believes that piperazin water is superior to the salicylates in the treatment of rheumatism and gout. He reports 2 cases—1 a woman of 66 years, 5 feet high, and weighing 223 pounds. She had incontinence of urine, and severe pains in the back, hips, knees, and ankles. The diet was restricted to whole meal bread and piperazin water; she rapidly lost weight, and gained strength, and was almost relieved from her pains. He also reports another case—a man 45 years of age, who had acute inflammatory rheumatism and was distinctly gouty. There was some fever, and all food was stopped; the piperazin water was applied internally and externally with excellent results. Page apparently believes that the autotoxemia, due to meat diet, are responsible for many of the ills to which we are heir. [J.S.]

Boston Medical and Surgical Journal.

October 4, 1900. [Vol. cxliii, No. 14.]

1. Remarks upon Obscure Nontraumatic Tumors of the Lower Abdomen Suddenly Appearing Where None had Previously Been Detected. MAURICE H. RICHARDSON.

3. Serum Therapy in Pneumonia. WILLIAM H. SMITH.
4. Case of Patent Foramen Ovale in Advanced Life. WILLIAM L. WORCESTER.

1.—Richardson calls attention to some **abdominal tumors of obscure origin**. The great emergency of pelvic surgery attended by the sudden appearance of tumors are ovarian torsion and extrauterine pregnancy. Appendicitis and salpingitis might be included, but both these diseases, present such definite histories and physical signs that the tumor so invariably associated with them can hardly be called obscure or unsuspected. A full bladder, acute dilation of the stomach, and a dilated colon or sigmoid flexure are also suggested as possible causes of such tumors. In most of the tumors under consideration pain is the first, the most important and enduring symptom. The diagnosis of ovarian tumor with twisted pedicle is easy when a tumor is known to exist. When one has not been found previously it is very difficult. It depends upon sudden pain, with or without signs of hemorrhage. The tumor is elastic and tender. The signs of strangulation, gangrene, peritonitis, are often obvious. The diagnosis of ovarian tumor with twisted pedicle must always be suggested by these symptoms. The diagnosis of extrauterine pregnancy is usually easy. Pain in the course of irregular menstruation, with dribbling of blood from the uterus, always suggests it. With any other confirmatory signs of pregnancy it is about certain. Most cases of extrauterine pregnancy are unaccompanied by any tumor of considerable size. The tumor, if any is found, is small. In spite of difficulties of diagnosis the signs point the right way—towards surgical intervention. It matters little whether the diagnosis of extrauterine pregnancy is wrong if the surgeon is guided to the relief of ovarian torsion, or if, expecting torsion, he finds extrauterine hemorrhage; if, expecting ovarian tumor, he finds a dilated stomach; or if, expecting an internal strangulation or an intestinal obstruction, he finds a dilated and twisted sigmoid flexure. It does matter, however, if, expecting to find a serious lesion, he finds a full bladder, or a normal pregnancy. In all suddenly appearing tumors of the lower abdomen, however obscure they may be,

intervention is demanded if the symptoms are the least urgent. [M.B.T.]

3.—Smith discusses the various attempts that have been made to secure an efficient antipneumococcic serum. It is possible to immunize mice; but the effects in human beings are less decided. A number of cases have been reported by Lara, Pone, Wiesbaker, and others. He calls attention to the results of Washbourne's serum obtained from an immunized pony. He concludes that there is hope for the future. [J.S.]

4.—Worcester reports the case of a negro of 57, who had served in the army during the Civil War; he died of general paralysis, and at autopsy examination of the heart showed a patulous foramen ovale 2.5 by 2 cm. in dimension, and a small communication between the ventricles immediately below the right semilunar valve; the heart was moderately hypertrophied, the physical signs were a long, loud murmur, systolic in time, that, as long ago at 1890, could be heard over the entire chest. [J.S.]

1. The Modification of Milk Laboratories. T. M. ROTCH.
2. Breast Feeding. A. WORCESTER.
3. Home Modification of Milk. CHARLES W. TOWNSEND.
4. Lesions of Chiasm; Temporal Hemipopia; Optic Atrophy; Probable Pituitary Tumor, With Gigantism and Defective Development (Preliminary Report). S. A. LORD.

1.—Rotch discusses some of the difficulties of milk modification. Errors may arise on account of the age of the milk, the number of bacteria it contains, and from carelessness in making the mixture; but the chief error is due to the variable percentage of the constituents; even slight variations in the per cent. of fat in the cream, for example, may give rise to considerable differences. A number of examples illustrating this, are given. Rotch, therefore, believes that the best solution of the problem is to be found in the well equipped and responsible laboratories that now exist in nearly all the large cities. [J.S.]

2.—Worcester gives an impassioned plea for the use of the human breast in feeding infants, believing that no substitute, however ingenious, can entirely replace it. It is particularly important to watch the mother and infant during the establishment of the nursing function. He believes that the nipples should be treated with unguents, and never with bad-tasting, so-called, cleansing solutions. [J.S.]

3.—Townsend is not entirely favorable to the milk laboratory for the artificial feeding of infants; he has 2 objections to it: (1) that by centrifugation the emulsion of the fats is broken up; (2) the excessive handling churns the milk, and also gives greater opportunity for bacterial infection; it is therefore necessary to pasteurize or sterilize the milk, especially in hot weather. He has devised a simple rule for home modification, as follows: Each ounce of 10% cream in a 20-ounce mixture, represents 0.5% of fat, 0.2% of albuminoids, and 0.2% of sugar; and each even tablespoonful of milk added to this mixture raises the percentage of sugar too. A 10% cream is obtained by allowing the milk to stand 6 to 8 hours, and pouring off the top layer. If it is desirable to increase the nutritive value of the mixture, raw white of egg may be added. He gives several illustrative cases of the benefits derived from modifications made according to this formula. Occasionally cereal waters are of advantage as diluents. [J.S.]

4.—Lord reports the case of a laborer of 32, nearly 6 feet high, with a very heavy skeleton. Three years before, he apparently commenced to grow nervous, had severe pains in the limbs, loss of appetite, and a year after the first symptoms, left amblyopia. Later, there was dryness of the skin, severe headache, and impairment of vision in the right eye. He lost considerable weight, and occasionally was dull and sleepy in the daytime. When examined, he was found to have temporal hemipopia in the right eye, the skin was dry, the hair thin, and the thyroid could not be palpated. The symptoms pointed to a lesion of the chiasm, probably a tumor of the hypophysis. The other symptoms of the case may be explained by ascribing them to glandular intoxications or degeneracy or to a disturbance of the chemic and physiologic equilibrium, resulting from a modified function of the thyroid gland. [J.S.]

- 3.—“ “ “ “ “ “ “ 1441.
- 4.—“ “ “ “ “ “ “ 1264.
- 5.—“ “ “ “ “ “ “ 1282.

6.—The following are the essential steps of the operation for movable kidney which Andrews calls the reefing operation: An incision is made at the outer border of the quadratus from the twelfth rib to the ilium. This is carried through the lumbar fascia and along the edge of the quadratus to the loose fat about kidney. The muscles are retracted and the fatty capsule split the whole length of the kidney. The 2 flaps thus formed are pulled outside, and the kidney thus held well up and back. Care should be taken that the lower pouch of this capsule is pulled high up. In cases of great prolapse, the fatty capsule will be found drawn into a long tube. Five or 6 inches of this fatty sac can sometimes be drawn up. The kidney will now lie snugly in the lumbar wound, and rise and fall in respiration. Probably it will be an inch or more below its normal place. This is an advantage, because it removes the pressure of the liver, and enables us to hold the entire organ, not merely its lower pole. The fatty capsule, and its enclosing, or Gerota's, fascia already drawn outside are now held by an assistant or by long forceps, while the opening in the muscular wall is closed by a line of mattress stitches which transfix the fatty capsule. The real support is obtained by compression between the muscles. The flaps should now be cut off an inch or two outside the muscle, everted and stitched down, after which the skin can be closed. Primary healing is easily obtained. Andrews has tested the operation in several cases for over a year and reports excellent results. Brief histories of 7 cases are given. [M.B.T.]

7.—Arneill reports a case of acute Graves' disease occurring in a married woman of 33. The chief points of interest in the cases are as follows: Cessation of menstruation 1 year before death, the appearance of the goiter 7 months before death, the advent 3 months later of palpitation of the heart, tachycardia and nervousness, immediately after a profound emotional shock, the presence of diarrhea and vomiting, great loss of weight—nearly 70 pounds in 4 months—high pulse-rate and high temperature toward the close of the illness, the presence of delirium and the complete absence of any evidences of exophthalmos. From a study of the literature he finds that this affection is extremely rare, only 2 cases having been previously reported in America. A necropsy could not be obtained in this case, but from a study of the cases which have been reported Arneill concludes that the only pathologic lesion which is found constantly present in these cases is the disease of the thyroid which is usually hyperplastic. He believes that if the histories of many of the reported cases of this disease had been worked out carefully, that in the majority signs, though indistinct, of a pre-existing incomplete Graves' disease could have been obtained. The fright, grief, or worry is simply an accidental factor, which has accentuated the signs present and hastened the development of others. The entire human family would be suffering from Graves' disease if fright, shock, and worry were sufficient causes. There is at this time either an unstable condition of the emotional nervous system, or the disease is present in its incipient stage. In the majority of acute fatal cases there is a history of uncontrollable vomiting and diarrhea, which soon exhausts the patient. [M.B.T.]

2. The Knowledge of Spinal Cord Affections Combined with Severe Anemias. OTTO MARBURG.
3. The Etiology of Basedow's Disease and Thyroidism. ROBERT BREUER.

1.—The authors report a case of typhoid fever in which there was a slight enlargement of the thyroid gland at the beginning of the disease, which increased and eventually ended in an abscess of the gland. In this abscess the typhoid bacillus was found unaccompanied by any other microorganism. The blood was carefully studied. In the beginning there was leukopenia with a relative increase in the lymphocytes; later, when the gland began to suppurate, a distinct leukocytosis ensued. The authors made a number of animal experiments to demonstrate the pyogenic power of the typhoid bacillus and the influence of the suppurations thus caused on the number of leukocytes. They proved that the typhoid bacillus produces suppuration, and that this power is independent of its virulence, barring the very virulent forms which, on account of their fulminant effects do not give time for suppuration. The leukopenia in typhoid fever is due to the localization of the disease in the organs chiefly concerned in the formation of leukocytes, and bears no relation to the poison of typhoid fever, since the latter, when located peripherally produces a leukocytosis. [D.R.]

2.—Marburg reports a case of pernicious anemia complicated with nervous symptoms resembling those of tabes dorsalis. At the autopsy extensive anatomic changes were found, entirely out of proportion to the clinical symptoms. The posterior columns were especially affected; to a less degree also the lateral tracts, particularly in the cervical cord. Marchi's method revealed the degeneration very well, but also showed black deposits in the posterior roots, which the author views as artefacts. The spinal lesions in pernicious anemia have been described by some as a myelomalacia or softening of the spinal cord; by others as myelitis. But the author found no round-cell infiltration, although the bloodvessels were decidedly altered. Yet he believes that the condition is one of myelitis, rather than one of myelomalacia, and thinks that the absence of round-

cell infiltration is dependent upon the grave anemia and consequent lack of oxygen. It has been shown by Bnz that oxygen is of great importance in the emigration of leukocytes. The localization of the lesions is connected with the distribution of the bloodvessels. [D.R.]

3.—The author reports a series of cases of acute thyroidism following the therapeutic use of iodine, and is of the opinion that the chronic iodine poisoning of older writers, which was observed particularly in cases of goiter subjected to iodine treatment, was nothing more than acute thyroidism. A woman of 56, with goiter, took for a few weeks about 13½ grains of sodium iodide per day. The thyroid gland became much smaller, but she lost flesh, was excitable, had tremor of the extremities, a hot skin, and rapid pulse. Under bromids and a milk diet the condition gradually subsided. In the second case a man of 69, with goiter, the use of sodium iodide had a similar effect. In the third case a woman of 58, with an old goiter, the use of potassium iodide for joint-pains brought on marked weakness, reduction in the struma, tremor, palpitation, rapid emaciation (particularly of the breasts), painless diarrhea, staring eyes, and von Graefe's sign, but no exophthalmus. The fourth case was that of a woman, 52 years of age, who had a slight enlargement of the neck. After the use of sodium iodide, taken on account of some ocular trouble, she developed weakness, emaciation, atrophy of the breasts, tremor, palpitation, and diarrhea. In none of these cases had there existed any symptoms suggesting exophthalmic goiter. In another series of cases (5) reported there have been mild symptoms of Basedow's disease, which were enormously aggravated by the use of iodine. In three of these cases this was employed in the form of an ointment; in one as a local application to the throat, and in the fifth, in the form of pills of potassium iodide. Another case is cited—that of a woman of 27, who had completely recovered from an attack of exophthalmic goiter—in which the application of iodine over a prepatellar bursa caused a return of the disease. Marburg believes that the iodine acts by causing an absorption from the gland of certain toxic substances contained in it. The reason that the toxic symptoms develop in only a small proportion of cases is to be found in individual idiosyncrasies. [D.R.]

July 26, 1900. [13. Jahrg., No. 30]

1. Glycerin as a Constituent for Antiseptics. OSCAR V. WUNSCHHEIM.
2. Report of 22 Cases of Artificial Interruption of Pregnancy. JOSEF V. BRAITENBERG.
3. Concerning Ferropyrin as a Hemostatic Agent. E. TOFF.

1.—Considering the frequent use of glycerine as a means for applying various medicaments, Wunschheim considered the investigation of its antiseptic properties of importance. He tested the effect of glycerine on various forms of germs, alone and in combination with various antiseptic preparations. It has no special value as an antiseptic, and if used in combination with carbolic acid and other preparations the antiseptics must be stronger than if used with water. A concentration of 10% carbolic acid is about as effectual as a 5% solution in water; but if the glycerine be mixed with equal parts of water, the disinfectant value is equally as good as in the pure aqueous solution. [M.B.T.]

2.—Braitenberg reports 22 cases of artificial interruption of pregnancy at the gynecologic clinic at Innsbruck. These cases occurred during a period of 3 years and in a total of 7,472 births. In 8 cases the interference was with especial consideration for the life of the mother; in 14 cases for that of the child. The causes stated were: contracted pelvis, acute hydramnios, nephritis, uncontrollable hemorrhage, pyrogallie acid poisoning due to treatment with pyrogallie acid given the patient for psoriasis at the skin clinic, and flat, rachitic pelvis. Two of the patients died, 1 of septic peritonitis; one 2 months after delivery, of phthisis at the medical clinic. Six children left the clinic alive with their mothers. The various methods of producing abortion used were colperysis, tamponing the cervix, inserting bougies, puncturing the membrane, and hot baths. [J.S.]

3.—Toff recommends ferropyrin as a hemostatic agent in severe nosebleed, incised wounds, etc., in which there is persistent oozing. It is a combination of chlorid of iron and ant pyrin which has all the hemostatic properties of ferric chlorid without any of its caustic properties. [M.B.T.]

Berliner klinische Wochenschrift.

July 30, 1900. [37. Jahrg., No. 31.]

1. Surgical Opening of New Collateral Ways for the Blood of the Vena Porta. S. TALMA.
2. Concerning Hemolysins. P. EHRLICH and J. MORGENROTH.
3. Concerning Phenylhydrazin and Anemia. KAMINER and ROHNSTEIN.
4. The Question of General Infection in Urinary Diseases. POSNER and COHN.

2.—Ehrlich and Morgenroth publish another lengthy article on **hemolysins**. They point out the similarity between toxins and hemolysins. The hemolysins consist of complement and immune body (immunkörper). The immunkörper corresponds to the haptophorous group of the toxin, while the complement represents the toxophorous group. They take issue with Bordet and Buchner in regard to the nature and number of the alexins or complements. They maintain that there is a plurality and that the normal serum contains a large number of complements. They believe that in the normal metabolic processes of the cells a large variety of lateral chains are cast off, which either singly or in unison with others unfold specific action. They would designate all such lateral chains circulating in the serum as haptins. It is also possible to produce anticomplements in the blood by proper treatment of animals. When mixed with complements they suspend the action of the latter. The complements normally circulating in the blood of an animal are not capable of producing anticomplements in that animal's blood. [D.R.]

3.—Many attempts have been made to produce experimentally the clinical picture of **pernicious anemia**. Fallquist used pyrocin, and the authors have employed **phenylhydrazin**. A large dose injected into animals produced death in 48 hours. During this time the erythrocytes sank to one million and even lower. Within 6 hours after the injection fragmentation of the red corpuscles and macrocytes were visible, but there was no poikilocytosis, although there was a moderate leukopenia. There was also a marked polychromasia of the red corpuscles in the stained preparations; some did not stain at all. Nucleated red corpuscles also appeared, chiefly normoblasts, but also megaloblasts. In these erythroblasts the granulation described by Pohn and Grawitz could not be observed. If the dose of poison injected was smaller a chronic anemia could be induced, consisting in a reduction in the number of red corpuscles and the appearance of large-sized macrocytes. No poikilocytosis was obtained. Nucleated red corpuscles were rare. The leukocytes were generally increased. Phenylhydrazin seems to act upon the leukocytes in a manner similar to that of toxins, acting in large doses as a negative chemotactic, and in smaller doses as a positive chemotactic agent. [D.R.]

4.—Posner and Cohn have made some experiments to discover whether bacteria injected into the lower part of the urinary tract enter the kidney and the general system. They laid bare the ureter and injected into the proximal end various kinds of bacteria. They found that the anthrax bacillus always led to a general infection. In the case of the *Micrococcus prodigiosus* 3 experiments were negative. The *Bacillus coli* always gave a negative result. The *Staphylococcus aureus* and *albus* and the *Streptococcus* gave positive results in 5 cases. The experiments produced, of course in a very exaggerated degree, the conditions obtained in the human body. In the ordinary pyelitis there is merely a local inflammation without retention of urine, which only sets in in late stages. They conclude, however, from their experiments that those forms of pyelitis which depend upon the *Bacillus coli* are less dangerous for the system from the standpoint of general infection than those caused by the ordinary pyogenic microorganisms. [D.R.]

July 19, 1900. [26. Jahrg., No. 29.]

1. Pasteur's Theory of Inoculation Against Hydrophobia. MARX.
2. Preparation of Antiplague Lymph from the Peritoneal Exudate of Infected Animals. CAMILLO TERNI and IVO BANDI.

8. Report of the Influenza Epidemic in February, 1900, in the Maternity Clinic in Greifswald. G. MÖLLER.
4. Experiments Concerning the Parasitic Nature of Eczema. W. SCHOLTZ.

5. Concerning Tetanus and Other Toxic Forms of Convulsions with Stomach Dilation. HANS URY.

1.—Marx has found that "virus fixe" is harmless when given to monkeys by intramuscular injection; also that when these animals are inoculated in the anterior chamber of the eye, they are infected, but not promptly, and not under the typical picture of hydrophobia. The fact that the passage of the hydrophobia microbes through rabbits modified the action of the virus in 2 forms of monkeys in such a way as to demonstrate that the virulence was weakened or the resistance of the microbes was decreased, demonstrates the possibility that the fixed virus in human beings may be a modified hydrophobia virus. This seems more probable when the absence of danger in the use of **antihydrophobia inoculations** is considered, and the explanation of the valuable effects of such prophylactic injections as being the result of such a modification of the virus seems very reasonable. [D.R.]

2.—Terni and Bandi have prepared an **antiplague lymph** from the peritoneal cavity of animals by injecting guineapigs with cultures of plague bacilli in Löffler's bouillon introduced into the peritoneal cavity. The animals died after 36 to 48 hours; immediately after death the fluid in the peritoneal cavity was collected under antiseptic precautions, was kept at 3° C. for about 12 hours and was then sterilized for 2 hours at 50 to 52° C. on 2 successive days; a mixture of carbolic acid 5%, sodium carbonate 25%, and sodium chlorid 75% solution were added in quantities determined by the thickness of the fluid and the amount of solid elements in it and this fluid then used for test purposes on monkeys, guineapigs and rats. It was found to be fully as effective as Haffkine's lymph, and it did not show the unfavorable after-effects and local irritation which are observed after using Haffkine's fluid. The dose can also be carefully measured. [D.L.E.]

3.—Twenty-one cases of **influenza** were observed in a maternity clinic during pregnancy and at the time of labor. Influenza had an unfavorable influence upon the early months of pregnancy. One case ended in abortion with high fever. In 10 instances the labor came on during an attack of influenza, and in 5 of these cases it was at the beginning of the ninth month. In the mild cases the course of the pregnancy and the condition of the child were apparently not influenced. The pains were energetic and the labor was short in many cases, but the uterus is likely to be readily worn out and its action must frequently be stimulated. Puerperal bleeding was common and the uterus reduced in size only slowly. [D.L.E.]

1. Two Cases of Tumor of the Cerebellum. SCHEDE.
2. Tetanus Poisoning. S. MIYAMOTO.
3. Experiments Concerning the Parasitic Nature of Eczema. W. SCHOLTZ.
4. Concerning Tetany and Other Tonic Forms of Convulsions with Stomach Dilation. HANS URY.
5. The Early Diagnosis of Intestinal Carcinoma. EUGEN HOLMÄNDER.
6. Are the Spontaneous Fracture of the Metatarsal Bones to be Considered as Accidental? GUSTAV MUSKAT.

1.—Schede reports 2 cases of **tumor of the cerebellum**. In the first case there was severe pain at first, confined to the occiput and back of the neck, but later spreading over the whole head. Disturbances of vision and hearing, accompanied by dizziness, gradually developed until he could scarcely hear at all, could only distinguish blue and white, the right eye showing $\frac{2}{3}$ and left $\frac{2}{3}$. The patient would fall if he attempted to turn while standing. The symptoms pointed towards a right-sided tumor, but at the operation a small, hard encapsulated growth, weighing 18 grams, was found on the surface of the left half. The tumor was easily removed with the finger, and as soon as its removal was accomplished the cerebral pressure, which had been intense, so relaxed as to allow the dura to be easily sutured. The result of the operation was most satisfactory, the patient being once more able to see and hear, while the

dizziness had entirely disappeared. The second case was a boy of 17, who had had headache for a year, beginning in the forehead and accompanied by severe tinnitus aurium and temporary disturbance of vision. The most marked symptom was the great disturbances of equilibrium, the patient being unable to stand at all, even with his eyes open. At the operation, a smooth-walled cyst, about the size of a walnut, was found near the median line. The contents of the cyst were evacuated and drainage established. The tumor in this case was thought to be a cystic sarcoma, so that a permanent recovery could not be hoped for. [G. N. W.]

2.—Miyamoto used for injection some old bouillon culture of tetanus bacilli, which had been kept for 2 years, and which did not kill mice with symptoms of tetanus, but did cause death through general weakness; hence, the spasms had largely disappeared. There was no tetanolysin present as it did not have any influence upon the blood-corpuscles of a defibrinated guinea pig blood in sodium chlorid solution. Hence, the appearance in the animals injected of a tetanus sine tetano was not due to tetanolysin, but to a combination of some other poison contained in the fluid with the components of other organs than the central nervous system, and the changes which occur in this toxin must be considered to be the result of the production of a toxoid, together with a general destruction of the true tetanus toxin. [D. L. E.]

3.—Scholtz found in a large series of cases of diseases of the skin other than eczema, a mixed bacterial flora in which there were a few yellow staphylococci, but these organisms were never present in large number and did not penetrate into the deeper layers of the skin. In eczema the Staphylococcus aureus was present in practically pure culture in all cases and invaded the deeper layers of the skin. Hence, he thinks that eczema may be considered to be due to a staphylococcus infection. A routine treatment with antiseptics, however, is not called for, since there is always some preliminary cause, such as abrasion or friction, to give opportunity for the staphylococcus infection, and the infection itself is not so important as the inflammation of the skin which is caused thereby. Antiseptics which are not so irritating as to increase the actual skin inflammation are valuable, and these are commonly used in eczema and will be much more effective than any stronger antiseptics which will be likely to increase inflammation, though destroying the germs. [D. L. E.]

4.—Ury reports a typical case of gastric tetany which ended fatally, and another case of gastric trouble with tetanoid symptoms but without true tetany, which ended favorably. He considers that the case of tetany are probably always fatal, while the tetanoid cases are the ones which are reported as recoveries from gastric tetany. Paresthesias in the hands and arms are often observed in real tetany as prodromal symptoms of the onset of the attack. A repetition of an attack of true gastric tetany is always exceedingly dangerous and should be avoided if possible. In the true tetany he considers operation to be strongly indicated, while in the tetanoid cases the indication is not so strong. [D. L. E.]

5.—Holländer gives some interesting family histories from cases of carcinoma of the intestine, which show a most striking family tendency to carcinoma of some form, chiefly of the gastrointestinal tract. In the first case the husband and wife, who had indistinct history of carcinoma, and a son and daughter died of carcinoma; in the next generation 4 children died of carcinoma; in the next generation 2, and in the next generation, 3. In another instance reported, 1 case occurred in 1 generation; in the next generation, 4 cases; in the next generation 2 cases (generation in these instances being used in the sense of including the collaterals as well as the direct descendants). He considers such a family history of carcinoma a very important point in the diagnosis of carcinoma of the intestine, since it seems to be intestinal carcinoma in which such striking family history is most commonly met. Another point which he considers of much importance is the occurrence of skin changes, chiefly in 3 varieties: first, vascular changes; second, seborrheic warts, and, third, pigmented patches. The vascular changes consist in the appearance of large numbers of small spots, of the size of a pinhead to that of a pea, which have the appearance of small angiomas. The warts are likely to occur in very large numbers and may reach a very marked size. He had seen them as large as pigeon's eggs. The pigmented areas vary in appearance and depth of color, but

may involve practically the whole body. These signs he has found very common in intestinal carcinoma. [Pigmentation of the skin can scarcely be considered a very valuable sign of intestinal carcinoma as distinguished from other abdominal tumors. It is not infrequently seen in abdominal growths other than intestinal carcinoma. D. L. E.]

6.—Mu-kat says that the so-called spontaneous fracture of the metatarsal bones should be considered as an injury the result of accident and that the fracture occurs instantly on receipt of the fracturing force. The reason that the injury is not followed immediately by disablement and other symptoms of a broken bone is due to the accuracy with which the surrounding structures splint, as it were, the 2 fragments. Pain and loss of function follow after continued use of the parts which results in a separation of the fragments. These conclusions have been arrived at after a study of cases occurring in the army. [O. N. W.]

1. The Future of Medical Jurisprudence in Prussia. G. PUPPE.
2. A Cured Case of Diabetes Mellitus. ZAUDY.
3. The Quantitative Condition of Carbohydrate in Diabetic Urine. HEINRICH ROSIN.
4. Concerning Benzyl-ester and Carbohydrate in Diabetic Urine. FREIHERRN V. ALFTHAN.
5. Concerning Metatramatic Alimentary Glycosuria. M. HAEDKE.
6. Usefulness of the New Saccharometer for the Quantitative Estimation of Grape Sugar in Urine. A. SPAETHE.

2.—Zaudy describes the case of a man of 50 who was excessively fat, who excreted as much as 5 liters of urine in a day, which contained at times nearly 300 grams of sugar, and in which at various times they found acetone, diacetic acid, and a substance which was probably B-ta oxybutyric acid. It was therefore a very pronounced case of diabetes. He had been rather seriously sick for over 3 years. He was put upon antidiabetic diet and salol and the sugar disappeared after a time. The patient did not stay in the clinic long, but when examined about a year afterward it was found that upon fairly free diet he excreted no sugar, and there was no albumin, acetone, or diacetic acid in the urine, and the amount of urine was rather less than normal. The carbohydrates were not increased, however, for fear of bringing back the sugar excretion. It was after the use of salol that the sugar disappeared from the urine; after 2 days' use of this drug, in amounts of 4 grams a day, the sugar sank to a very low point, and on the fourth day it practically vanished; hence, it seemed to be distinctly effective, though no very decided statement is made by Zaudy. [D. L. E.]

3 and 4.—The work referred to by Rosin was a portion of that carried out by Alfthan; the 2 may therefore be considered together. The first point investigated was whether in diabetes unfermentable carbohydrates as well as the fermentable are increased in the urine. The former were determined quantitatively by Baumann's benzoyl chlorid method. It was found that in the normal person the amount of the benzylesters per day varied in grams from 1.5 to 5; in diabetes, on the contrary, the amount varied from more than 9 grams to over 20, and the amount stood in no direct relation to the amount of sugar in the urine. Evidently, then, there is in diabetes an increase of the carbohydrates in the urine which do not ferment, though whether this is true in all cases is of course not yet known. It is also a matter of interest, and perhaps of prognostic importance to learn whether these unfermentable carbohydrates reach the normal amount when sugar disappears from the urine in diabetes. The further study of the unfermentable carbohydrates is likely to make the knowledge of the metabolism of the carbohydrates much wider. It was also discovered that the amount of carbohydrates insoluble in alcohol was much greater in the urine that had not been fermented than in the urine which had fermented; hence, some of the carbohydrates insoluble in alcohol seem to ferment; also, a substance which showed the characteristics of Landwehr's animal gum was isolated and the curious fact was observed that this would reduce copper but not Nylander's reagent. This is probably due to the fact that a mixture of gum solution and sugar solution will, if the gum is present in excess, not reduce Nylander's solution, though it does reduce copper. A case of diabetes insipidus showed marked reac-

tion to a naphthol and sulphuric acid when diluted 30 times, while normal urine shows no reaction when diluted from 10 to 15 times; hence, it was probable that nonfermentable carbohydrates were increased in this case also, a fact which may prove of much interest in the question of the relation between diabetes mellitus and diabetes insipidus. [D.L.E.]

5.—Haedke examined a series of 25 cases in the surgical clinic, chiefly those who had some serious injury of the head and other parts of the body. He always excluded those who had been at all intoxicated at the time of the injury, and those who had any history of excessive use of alcohol. He also endeavored to exclude decided arteriosclerosis, lead-poisoning, and the like. He gave 100 grams of pure grape-sugar in watery solution. **Alimentary glycosuria** was observed in 15 of the 25 cases examined. This is a much larger percentage of cases than in others who have not been subjected to injury; in control investigations of 20 people who were all markedly alcoholic, Haedke found only 2 in which alimentary glycosuria was present. In none of the series of cases was he able to cause a glycosuria by giving starches, and in no case did a true diabetes follow upon the glycosuria. [D.L.E.]

6.—Spaethe has made a series of control investigations of the **saccharometers** devised by Einhorn, Andt-Fiebig and Lohnstein (the latter's having 2 forms). He finds that the improved Lohnstein saccharometer has not the points of error that are seen in the others and that it gives accurate results. It is also simple and readily used. [D.L.E.]

Münchener medicinische Wochenschrift.

August 7, 1900. [47. Jahrg., No. 32]

1. The Indications for Surgical Interference in Extrauterine Pregnancy. L. PROCHOWNICK.
2. Nervous Disturbances in the Region of the Brachial Plexus in Angina Pectoris. L. LOEWENFELD.
3. Xeroderma Pigmentosum. K. HERXHEIMER and R. HILDEBRAND.
4. Pathogenesis of Gout. O. HAGER.
5. Suturing of Arteries. RUDOLF SEGGER.
6. The Corset and Reform Dress. JUSTUS THIERSCH.
7. Remarks upon Starvation. HARTMANN.
8. Heinrich Bose. POPPERT.

1.—Prochownik testifies to the difficulty of always making a certain diagnosis of **extrauterine pregnancy**. Formerly he was an advocate of conservative treatment, but he now advises operation in many cases. He bases his change of opinion upon the results of his own experience and gives a comparative, tabulated statement of 139 cases, 47 of early operation and 92 of conservative treatment, in 40 of which surgical operation was the last resort. He usually prefers laparotomy, and adds that his observations have in the course of years verified the statement that a previous infection of the genitalia is very frequently the cause of extrauterine pregnancy, and induces tubal abortion and hematocele. [W.K.]

2.—Loewenfeld discusses the **nervous disturbances in the brachial plexus occurring in angina pectoris**. They are sensory, motor, and vasomotor. The inner side of the upper arm, the anterior surface of the forearm, the ring and little fingers, and the ulnar side of the hand are most frequently affected. The motor disturbances involve exclusively the left arm and consist in a marked weakness. Occasionally there is a convulsive tremor of the left arm. The vasomotor phenomena manifest themselves as coldness and pallor of the left hand. The case is cited of a man of 52, who felt pains in the arms after carrying a knapsack. The attacks occurred periodically, and beginning in the shoulders radiated into the arms, especially the left, into the region of the sternum and the left side of the thorax; rarely into the right side. The heart was a little enlarged and the sounds feeble. During the attacks the left hand was pale and cold. In time the paroxysms in the left arm became excruciating, and in the intervals it was possible to produce pain by passive motion of the left arm and shoulder, and the brachial plexus was tender above the clavicle. Death occurred in an attack while the patient was at stool. The autopsy showed **calcification of the coronary arteries and atrophy and dilation of both ventricles**. Another case is cited in

which the pain in the precordia was slight compared with that in the arm, the patient also dying suddenly in an attack. Regarding the nature of the brachial symptoms, the view of the majority of authors is that they originate from the cardiac plexus, pass through the 2 lower cervical ganglia into the spinal cord, and thence out along the brachial nerves. This explanation does not seem quite suitable for those cases in which the paroxysm of angina start in the arm, or in which the brachialgia predominates. If the same theory is to apply we must assume that the irritation starting in the cardiac plexus is manifolded and intensified in its transit. The brachial plexus in the author's case showed on staining atrophy and sylerosis, and he believes on the strength of this that the neuralgic attacks in the left arm were due to a primary and independent disease of the brachial plexus. The angina was a complement or consequence of this neuralgia. The anginal attack may begin either in the cardiac or in the brachial plexus. The author's final conclusions are that the brachial neuralgia may be a consequence of angina or may exist as an independent concomitant affection. In the latter case the 2 have no causal connection, but have a reciprocal influence for the worse. He thinks that brachial neuralgia is due either to changes in the nerves or to the same cause as the angina pectoris, an organic heart-lesion. [D.R.]

3.—The author reports 4 cases of **xeroderma pigmentosum**, one in a man of 70, 2 in brothers, and one in a girl of 5 years. The points illustrated by the cases are that the disease is not necessarily fatal at an early date, as has been maintained, and that the early occurrence of malignant tumors is not of necessity a sign of particular malignancy on the part of the disease. [D.R.]

4.—A summary concerning the **pathogenesis of gout**. The author rejects the old view of Garrod that the essential element of gout is the deposit of uric acid in the joints, and believes that this deposit is only a symptom, as is also the increase of uric acid in the blood. The deposit occurs in the joints secondarily to a **necrosis in the joint tissues**. This necrosis is brought about by the irritating action of certain **alloxur compounds**, particularly adenin, circulating in the blood. It has been shown that before the outbreak of an attack of gout there is a retention of nitrogen in the system. This retention is not accompanied by an increase in weight and is to be credited to the presence of nitrogenous extractives of the alloxur or uric-acid group. The adenin is the most harmful, producing necrosis of the tissue-cells. Why it does so in certain particular organs or parts, like the joints, is not definitely known, but it probably depends upon anatomic conditions. The necrosis induces an extensive disintegration of tissue-cells, and the decomposing nucleins of the latter lead to an accumulation of alloxur bases and uric acid in the blood. The uric acid thus produced, or that existing preformed in the blood, is deposited in the affected parts as tophi. The recent theory of Luff, according to which the primary fault is in the kidneys, is rejected by Hager. [D.R.]

6.—Thiersch inveighs against the use of the **corset**, and also denounces the custom, much more prevalent in Germany than elsewhere, of wearing a large number of skirts suspended from the hips. [D.R.]

7.—In a man who had **starved to death** the principal lesions were complete emptiness of the digestive tract, except for the presence in the lower part of the descending colon of small, greenish-black, faceted scybala, the absence of blood from the organs, and moderate wasting of different viscera. In addition to these findings the diagnosis of death from starvation (the case was a medicolegal one) was based upon the statements of witnesses and upon the absence of all other efficient causes of death. Differing from previous observations, there was in this case not much wasting of the subcutaneous fat. [D.R.]

Centralblatt für innere Medizin.

September 15, 1900.

1. Is Strychnia Antidoted by Living Animal Tissue? S. J. MELTZER and G. LANGMANN.

1.—The authors have investigated further the statement of v. Czyhlarz and Donath (same journal, 1900, No. 19) that

when strychnia is injected into an extremity in which absorption is temporarily prevented by a tight ligature, the drug does not have a poisonous effect. Their work upon snake-poison in guineapigs and rabbits shows that the occurrence of death was postponed but never prevented when a tight ligature was placed upon the proximal portion of a limb and taken off 3 or 4 hours after the strychnia was injected. Snake-poison was not considered to be very demonstrative of any results, since it is not particularly poisonous in guineapigs at any rate. The same thing also occurred, however, if the limb was first ligated for several hours, the ligature then being removed and strychnia injected. Strychnia was used in frogs and rabbits because they show special sensitiveness to this drug. The results as to actually antidoting the strychnia in the ligated limb were negative in both frogs and rabbits. In guineapigs minimal doses were found to be much less violent in action, or the occurrence of convulsions was entirely prevented. These results they reduce to the statement that in guineapigs, which animals have but slight sensitiveness to strychnia, the application of a ligature prevents the absorption of this drug to some extent. That it is due to prevention of absorption and not to actual antidoting of the drug was shown by the fact that both extremities were ligated and double the minimal dose was injected. In these cases tetanus was produced without exception. Under these circumstances, then, each leg had absorbed sufficient to make the combined amount productive of poisoning. This was even more clearly shown when 3 extremities were ligated and in each one a minimal dose was injected. This gave a much larger space for absorption. As the authors anticipated, after the removal of the ligatures severe tetanus developed. They therefore attributed their results to the hindrance of absorption rather than to an antidotal effect. [D.L.E.]

Centralblatt für Gynäkologie.

July 28, 1900. [No. 30.]

1. Upon Vaginal and Uterine Dilation. BOSSE.

1.—Bosse presents an exhaustive resume of the advantages of vaginal and uterine dilation in obstetric practice. Of the various methods of dilation he prefers that by means of the colpeurynter, and says that Champetier's balloon is the instrument par excellence. The advantage of this method over dilation with bougies, is that the result is more certainly obtained in much less time; and, in general, it is especially adapted to cases in which artificial premature delivery is indicated, to cases of combined version on account of placenta previa, or of severe eclampsia; or cases of pneumonia or heart-failure complicating pregnancy and labor. [W.K.]

1. The Question of Retention of Ovarian Remnant. ISIDOR FISCHER.

2. Face Presentation: Chin Posterior. MODEST POPESCU.

1.—Fischer says that but little is known as to the fate of a fragment of ovarian tissue left behind in operating. He reports a case in which a woman, aged 22, underwent an operation for tumor of the adnexa in which both tubes and ovaries were removed except a portion of the right ovary near the hilum about the size of a hazelnut, which seeming normal and healthy was permitted to remain. One year after the operation a cyst about the size of the fist had developed from this remaining ovarian tissue, which it was subsequently necessary to remove also. [W.K.]

2.—Popescu describes a case of face presentation, chin posterior, in which by means of forceps the head was turned, so that the chin was in the middle of the right pelvic wall, and the forehead in the middle of the left; and then the child was extracted. The operation was difficult and attended with much loss of blood and resulted in the mother's death the next morning. He thinks the lesson taught by this experience is, that in such cases it is better to abandon the life of the child and, in the interest of the mother's life, advance at once to the perforation even of a living child. He would therefore forbid the use of forceps, not only in the high transverse presentation of the face, but also in face-presentation, chin posterior. [W.K.]

2. Chinosol in Midwifery Practice. By H. TJADEN.

2.—Tjaden continues the discussion of the advantages and disadvantages of chinosol as a germicidal and disinfecting agent for sterilizing the hands of midwives in their obstetric practice. [W.K.]

Neurologisches Centralblatt.

September 15, 1900. [No. 18.]

1. Acute Disturbance of Motility, with the Characteristics of Cerebellar Ataxia, Developing in Alcoholics. von BECHTEREW.

2. Further Communications Concerning the Narrowing of the Pupil that occurs upon Forcible Closure of the Eye. J. PILTZ.

3. The Clinical Position of the So called Erythrophobia. A. FRIEDLÄNDER.

4. A Case of Paralysis of the Lower Portion of the Brachial Plexus, following Gunshot Wound. II. BRASSERT.

1.—von Bechterew calls attention to the peculiar form of ataxia that develops after excessive indulgence in alcohol, and following the subsequent coma or sleep. The patient suddenly discovers that he has difficulty in standing upright; there is a feeling of subjective vertigo, and occasional nausea or vomiting. In the course of time all symptoms excepting the ataxia disappear, but the latter may persist for an indefinite period. This ataxia is only observed when the patient stands upright, or attempts to walk; the movements of the individual limbs are normal. Occasionally there is tremor, or nystagmus, and sometimes inequality of the pupils; in a few cases epileptic attacks have preceded the condition. Treatment consists of baths, potassium iodid, strychnia. The symptoms are probably caused by a lesion in the cerebellum, although, as no autopsy has yet been obtained, this is still uncertain.

2.—Piltz, in continuation of his studies upon the pupillary reflexes, reports a remarkable case in which there was complete paralysis of the muscles of the eyeball, and a pupil that failed to react to light or accommodation. A vigorous closure of the eye caused, however, a distinct narrowing. He also reports 6 cases, in all of which closure of one eye, or attempted closure against resistance, caused narrowing of the pupil of the other eye. The diagnoses were: parietic dementia, 2 cases; tabes dorsalis, 1 case; precocious dementia, 1 case, and neurasthenia, 2 cases. He supposed that this is due to a transmission of energy from the facial muscles to both centers for the contraction of the pupils. He then gives an analysis of a considerable number of cases, including 32 of parietic dementia, and 31 of katatonia. He finds that among the former, contraction of the pupil upon forcible closure of the eye occurs more frequently than in normal persons, and in the latter, contraction upon attempted closure of the eye against resistance, although the light reflex is present. He gives a complicated explanation of this phenomenon. In conclusion he reports a case of traumatic paralysis of the iris, in which only the orbicular reaction of the pupil was preserved. [J.S.]

3.—Friedländer gives a preliminary section of a paper upon the clinical position of erythrophobia, that is a morbid fear of blushing. The first case was observed by Casper in 1846. The name was first used by Boucher in 1890. [J.S.]

4.—Brassert reports the case of a man, 57 years of age, who at the age of 17 was shot through the breast, just below the right clavicle; this was followed by paralysis of the right hand, and disturbance of sensibility and pain in various regions; there was hyposthesia in the lower third of the arm, followed subsequently by wasting of the muscles of the hand. Forty years later the condition was as follows: weakness of the muscles of the shoulder and arm, atrophy of the flexors and pronators in the forearm, and atrophy of the thenar, hypothernar, interosseal and lumbrical muscles in the hand. There was mainengriffs, sensation was diminished in the ulnar region, and slightly in the median region, the degenerated muscles failed to react to electricity; there were no disturbances in the pupillary reflexes; there was some stiffness of the joints. The case represents the form of paralysis described by Klumpke. [J.S.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Atrophic Rhinitis.—Douglass (*Post-Graduate*, June, 1900) states that the complete removal of the scabs and the cleansing of the nares and pharynx constitute an important part of symptomatic treatment. Patients should be made to understand that the physician should see them every two days, or better daily; that all scabs can only be removed by cotton dipped in some solution and carefully applied to loosen. Every nook, furrow, and fold must be carefully searched. Patients realize only too well that the douche does not remove these scabs. The best results are obtained from the use of an antiseptic and deodorizing solution applied twice daily, followed by the medicant we may choose, and on alternate days these cases should be carefully cleansed at the physician's office. A spray of hydrogen peroxid (1 to 10, or 1 to 20) seems to soften and loosen scabs well, and is both an antiseptic and deodorizer. After complete spraying and a wait of a couple of minutes this should be washed out with warm normal saline solution, used in either the nasal syringe or douche-bag. This spraying and douching can be repeated until a quart of water has been used. When the odor is very offensive a solution of mercury bichlorid (1 to 10,000) may be used with the salt in the douche. The use of trichloroacetic acid (1% solution for home use and 2 to 5% solution for office use) sometimes acts favorably, but according to Douglass it is less satisfactory on the whole than other methods. With citric acid the author has had no experience. Ichthyol is a drug which gives the greatest relief. Nearly all laryngologists agree that it is the most valuable remedy for the relief of the disagreeable symptoms and the best stimulant for the mucous membrane. Douglass employs ichthyol in three ways: First, by means of a 10 to 20% aqueous solution applied on a large pledget of cotton and introduced into the nares upon the atrophied areas. As soon as the nares have been cleansed the pledgets are introduced and the patient allowed to sit in the outer office for 15 to 30 minutes, after which the pledgets are removed and the oily sprays are used to conclude the treatment. When there is ulceration, for persistent flow of pus, ichthyol in full strength may be rubbed directly into the parts. Ichthyol on cotton wound on a probe is gently rubbed for 4 or 5 minutes into the atrophied mucous membrane. The third method of using ichthyol is by means of a salve:

R.—Ichthyol 40 grains.
Menthol 5 grains.
Vaselin 1 ounce.

To be used after cleansing the nostrils and at bedtime. The patient is directed to insert a piece as large as a bean and then to snuff it back. When the odor is intolerable, as arises from necrotic bone, orthochlorphenol in solution with glycerin of the strength of 10 to 25% seems to work well. In 10% solutions it is a strong stimulant. In solutions of 25% it is a decided cauterant, the great objection to its use being the odor of phenol which it possesses. It must be used with caution.

The Use of Morphin in Surgical Practice.—Edward Martin (*Therapeutic Gazette*, September 15, 1900) states that the general indications as to the employment of morphin in surgery may be summed as follows: 1. Morphin should be given hypodermically and in doses sufficient to accomplish the purpose for which it is given. 2. When surgical shock is attended by such severe pain as to cause uncontrollable restlessness, morphin should be given in doses adequate to relieve it. The same treatment is indicated for shock-restlessness without pain (usually due to hemorrhage) the appropriate general treatment for shock also being carried out. 3. Morphin is the best internal hemostatic in the treatment of hemorrhage; when the hemorrhage is complicated by restlessness morphin is absolutely indicated because of its quieting effect upon both mind and body. 4. When drunkards, or exceptionally neurotic patients, are to be anesthetized a preliminary hypodermic injection of morphin renders such anesthetization quicker, easier, and safer, and favorably effects the stage of recovery. Obstinate and exhausting

vomiting after ether is sometimes relieved by morphin. 5. If in the first 24 hours after operation pain becomes so severe as to cause uncontrollable restlessness, this pain should be relieved by morphin. To this rule there are practically no exceptions; it applies to all operations regardless of the operative area. 6. When used in accordance with these indications the beneficial effects of morphin so overshadow its injurious effects that the latter are not demonstrable. To this rule there may be a very few exceptions.

Enemata for Use After Abdominal Sections.—Hunter Robb (*Cleveland Medical Gazette*, September, 1900) states nutritive enemata should not be given oftener than every 3 or 4 hours for fear of rendering the bowel intolerant of them. The bowel should be thoroughly irrigated every morning with warm, normal salt-solution, so that the nutritive enemata will be better absorbed. The following enema is suggested:

R.—Peptonized milk..... 1 ounce.
Whisky..... 1 ounce.
Whites of 2 eggs.....
Table salt 24 grains.

For the distressing thirst which sometimes develops after abdominal sections an enema of one pint of tepid water may be slowly administered. For unloading the bowels a high enema of one pint of soapsuds in warm water may be allowed to run slowly into the bowel from a funnel. If this enema does not prove effectual it may be repeated, or one like the following substituted:

R.—Warm water 1 pint.
Olive oil..... 2 ounces.
Turpentine..... 2 to 4 drams.

It preferred, from 4 to 6 ounces of warm olive oil or glycerin may be first injected in order to soften the fecal matter, and an enema of soapsuds and water given an hour or so later. Occasionally the addition of an ounce of Epsom salts to the pint of warm soapsuds and water will act when other enema have failed.

A Case of Anthrax Successfully Treated by Local Injections of Pure Carbolic Acid.—Fisher (*Therapeutic Gazette*, August 15, 1900) reports a case of anthrax in a man, aged 36, who had been employed as a card-stopper in a large woolen mill. The disease began 8 days before admission. When first seen his temperature was 101° F., he complained of headache and weakness, the tongue was heavily coated and the bowels were constipated. The affected arm was very painful and considerably swollen. On the day after admission 1 dram of carbolic acid (10%) was injected into and around the eschar on the forearm. On the following day his condition was slightly improved, and 1 dram of pure carbolic acid was now injected into, around and beneath the eschar. These injections of pure carbolic acid were given daily for the next 4 days, after which the symptoms had almost entirely disappeared. At no time was carbolic acid detected in the urine, although the patient had had one injection of carbolic acid (10%) and 6 injections of pure carbolic acid in dram doses daily. After 3 injections the temperature fell to normal, and after 5 injections the eschar ceased spreading. Jarnorsky has reported 72 cases of anthrax, all of which were cured by the local injection of carbolic acid.

Diphtheritic Paralysis and Antitoxin.—Ransom (*Journal of Pathology and Bacteriology*, No. 4, 1900) concludes: 1. Paralysis may certainly be expected after intoxication with not less than one-fourth of the minimal fatal dose of toxin; it may occur with doses between one-fourth and one-eighth, but not when the dose is below one-eighth. 2. Antitoxin given 15 to 22 hours after intoxication, with doses not greater than the lethal dose, exercises in large doses a modifying influence on the subsequent paralysis. Small doses of antitoxin have no evident effect in diminishing the paralysis. 3. Transferring these results to practice among human beings, we may expect liberal doses of antitoxin, given early in the illness, to influence favorably the subsequent paralysis, and this beneficial influence is likely to manifest itself, not so much on the local paralysis (soft palate, etc.), as on such symptoms as failure of the heart. Severe cases, arc, however, likely to be followed by some paralysis in spite of even large doses of antitoxin.

THE SURGICAL MANAGEMENT OF UMBILICAL
HERNIA WITH LARGE RING.*By E. D. FERGUSON, M.D.,
of Troy, N. Y.

Fellow Members of our Association and our Guests:—
An umbilical hernia in its early history, when the opening through the aponeurotic covering of the abdomen is small and the contents of the sac can readily be returned, offers an opportunity for a relatively simple, safe, and satisfactory operation. In these early cases the simple denudation of the opposing surfaces of the small ring and the proper insertion of any form of coaptating suture usually secure a radical cure if done in an aseptic field. Even in these simple cases, however, it is probable that the operation will be best done by denuding the borders of the ring to the posterior level of the tendinous structures, after excision of the sac down to the ring, and then splitting vertically the edges of the ring so that the two layers of aponeurosis which enclose the rectus muscle may be separately closed by two layers of sutures. From the intimate adhesion of the peritoneum to the edges of the ring this expedient becomes a convenience, for in closing this posterior layer, if care in denudation has been taken it is manifest that the undenuded peritoneal surfaces can be approximated at the deeper layer of sutures by stitching through the denuded borders, while the upper layer will furnish opposing surfaces of pure fibrous tissue. The common difficulty found in dissecting the peritoneal sac free at the ring so as to preserve its integrity, renders the resort to denudation the easier method, and fully as satisfactory in cases with small rings. In closing the layers of the fascia in this way we have created as deep and strong a union in tendon tissue as can be made at that point, and if the healing of these tendinous layers proves to be aseptic, we may confidently expect a permanent cure.

It seems hardly necessary at present to restate the arguments in favor of suturing the separate layers of tissue entering into the hernial field so that like tissues only shall be approximated by the sutures, or to insist that the coaptation of fibrous tissue in the form of tendon, fascia, or aponeurosis, is the only curative expedient in our operations for hernia. It is well known that "through and through" suturing of a ring imperfectly denuded of its peritoneal covering is too frequently the course pursued even at the present time. In such cases the healing process is represented largely by the gluing together of the peritoneal borders of the ring without a welding of fibrous tissue,—a state of affairs quite likely to result in a recurrence of the hernia.

If failure to secure a permanent cure is the occasional result in cases of umbilical hernia with small rings, it is not surprising that in cases with large rings success should have proved the exception rather than the rule.

The mere fact that the hernia has a large ring implies the probable presence of certain conditions which add materially to the difficulties of the operation. In the first place it is probable that the hernia has existed for a long time and that more or less of the abdominal organs have formed adhesions to the inner surface of

the pouch. In fleshy patients it is difficult, if not impossible, to feel sure of a complete return of the contents of the sac prior to operation. I have several times been surprised to find considerable masses of omentum, or even loops of bowel fixed by adhesion well within the pouch where I had concluded from palpation of the ring, after the return of a large volume of hernial contents, that the sac was empty. This is readily accounted for by the broad or flat adhesion of omentum at the ring, or the collapsible state of the loop of bowel at that point, while the surrounding cushion of adipose tissue does not allow of the recognition of the omental mass of fat, or of the soft bowel which is free from the spring and resistance due to strangulation.

Then further, the puzzling relations of several loops of bowel imprisoned in a tangle of fibrous bands, ropes or honeycomb of omentum, and adhesions to the sac, offer problems which are often extremely embarrassing to the operator.

In cases in which the incarcerated content of the pouch is very large, not permitting a considerable reduction in the size of the hernia by rest in the dorsal position for several days, the patient is subjected to those risks which experience has shown to attend the sudden restoration of the contents of a large hernia to the abdominal cavity, a fatal result supervening in spite of careful and aseptic work. This class of cases is recognized for their operative difficulties and risks as well as for the tendency to relapse.

It is not my purpose, however, to dwell upon such elements of the procedure for the cure of umbilical hernia. My object is to exploit a method of closing large rings, and I shall only dwell upon the treatment of the sac and its contents in so far as it specially relates to that method. Neither will a strict definition of the size of a *large ring* be given, for in some instances a ring may be considered large when the distance is actually less than in one which cannot so be classed. The statement that the ring will admit two, three, or even four fingers, laterally placed, does not fully classify the cases, though giving a general idea of the actual size of the ring. *The essential feature of those rings which should be classed as surgically large, is the inability to approximate the borders of the ring by a vertical line of suturing without placing the parts thus sutured in a considerable and constant state of strain on the sutures.*

We cannot too strongly insist that any suture material at present available when subjected to considerable strain will either give way or so cut the tissues included in the sutures as to allow of a separation of the approximated borders before safe union has occurred. Who would expect an earring with its small wire to remain in the lobe of the ear if a constant weight of even a few ounces were suspended to the ring? And yet some of those large hernial rings are brought together by a force represented by several pounds, often breaking the silver wire in the process of coaptation, in the vain hope of securing a firm union. Separation of the apposed surfaces is practically inevitable in such cases, and the loop of wire, silkwormgut, or silk will be found on the side of the ring at which the individual stitch included a larger or stronger portion, as it would sooner cut through the opposite part. In this way I have found silver loops on opposite sides of the reopened ring, where the futile attempt had been made to hold forcibly by nonabsorbable material parts which were subjected to strain.

* The Presidential Address at the Meeting of the New York State Medical Association, October 17, 1900.

It seems to me that all procedures which are intended to secure permanent apposition of parts by nonabsorbable suture material are surgically wrong, for if union should not occur within the usual time, or if strain is to continue beyond the usual time of healing, or even to be considerable during that time, the sutures will so cut into the tissues as to defeat the attempt.

Any suture-material that remains much longer than is sufficient to allow firm union of the parts apposed by the sutures, becomes a foreign body with a liability to become the focus of irritative changes. Even absorbable sutures when overhardened by chromicising may remain so long as to give trouble, but such a result is an incidental factor and not a constant condition as with nonabsorbable sutures.

Before detailing the special operative expedient which it is my purpose to set forth in this paper, it will be well to recall the anatomic relations of the parts.

By reference to the diagram, Fig. 1, taken from Gray's Anatomy, showing a transverse section of the abdominal walls in the lumbar region, it is seen that the three muscles on the anterolateral aspects, namely the external oblique, the internal oblique, and the transverse,

FIG. 1.—From Gray's Anatomy.

have three aponeurotic tendons so disposed that the tendon of the internal oblique is split at the semilunar line, one half of the tendon uniting with that of the external oblique and passing in front of the rectus muscle, and the other half uniting with the tendon of the transverse muscle and passing behind the rectus. Both divisions come together at the inner border of the rectus, and are there blended with each other as well as with the tendons of the opposite side so as to form the linea alba.

It is this division of the aponeurosis of the internal oblique and the blending of the divisions with the aponeuroses of the two remaining muscles in passing respectively in front and behind the rectus muscle that furnishes the condition which led me to devise the operation. This division is nearly constant and may usually be counted on in practice, but in one case I found the layer of aponeurosis behind the rectus quite defective, in fact scarcely stronger than the fascia transversalis, a structure which is of service as an aid in preventing hernia, but not in itself sufficient, for in fact it is usually included with the peritoneum in the first layer of suturing in abdominal operations, the operator

not distinguishing or separating the fascia from the peritoneum. This disposition of the aponeurotic tendons of the abdominal muscles does not extend the whole length of the rectus, but only for the upper three-fourths of that muscle. At about midway between the umbilicus and the pubes the muscle penetrates the posterior layer of its sheath, the aponeurotic margin bordering the upper and free fold being known as the semilunar fold of Douglas. This change in the relation of the aponeurosis is so generally found at the indicated level that we may regard it as practically constant, so that for the distance of three inches below the umbilicus we will find a strong lamella of aponeurosis behind the muscle, and one in front of it, an extent usually sufficient for the expedient that I adopted. Of course this arrangement of the lamellae extends from the umbilicus upwards into the epigastric region, though the sheath becomes less in size and its parts more blended as the ensiform and the rib cartilages are approached.

Opposite the umbilicus and at two points above, namely, just below the ensiform cartilage and midway between that point and the umbilicus, the rectus is partly divided by tendinous material which penetrates the substance of the muscle to a greater or less extent, usually from the anterior lamellae of the sheath. These lineae transversae enable the muscle readily to act in sections, but they rarely penetrate the muscle so completely or firmly as to prevent the separation of the anterior lamella of the sheath from the muscle. In some cases, however, if we are to leave a continuous stretch of muscle it will be necessary to proceed carefully in the dissection through these transverse lines, otherwise we shall either destroy the continuity of the muscle, or render thin, or even penetrate the anterior lamella of the sheath. If in reconstructing a continuous protective covering in the abdominal walls, the problem arises as to which is more important, the muscle or the aponeurosis, we should always proceed so as to preserve the aponeurosis intact rather than the muscle. Even if the separation through the lineae transversae goes so deeply as to endanger the local continuity of the rectus muscle, if we do not seriously weaken either the posterior or anterior lamella of the sheath we shall have available material which will be efficient in the repair of a hernial opening.

As is well known, the lamellae which constitute the sheath of the rectus muscle as they pass to the median line blend with each other and with those of the sheath of the opposite muscle in what is known as the linea alba. This union is narrower below the umbilicus than above, but throughout its extent furnishes an example of very firm blending of aponeurotic tissue.

In the development of the embryo a weak point in this line is left by the umbilical vessels there entering the abdominal cavity. At the point of entrance of these vessels we may usually count on a firm blending of the anterior and posterior layers of the sheath of the rectus on each side of the vessels, but blending of the borders of these sheaths after the atrophy of the umbilical vessels is rarely so perfect as to render that part of the abdominal wall as strong as either above or below that point; hence when lateral strain becomes strong in lifting, pregnancy, childbirth, or other cause of strain or distention, this weak spot may yield and a hernia result.

The influence of pregnancy is manifest in the greater frequency of umbilical hernia among parous women. In the development of an umbilical hernia, the yielding is usually just at the point where the umbilical

vessels entered the abdomen, consequently, and on this point I wish to place emphasis, the hernial ring will be bounded by the linea alba at a narrow space at its upper and lower portions, and between these points on each side will be the blended borders of the two lamellae of the sheath of each rectus. This lateral blending of the two elements of that muscle-sheath is the key to the situation. It is usually a union of great strength, and even in cases where the ring has been quite freely excised and the borders approximated with through-and-through suturing, or other methods of closing the opening, should a relapse of the hernia occur, we may expect to find a strong union reestablished at the inner border of the rectus muscle between these two lamellae.

I wish to make my meaning clear on this point, for it is the key to the situation. At the center of the upper and lower portions of the ring the tendinous structures are blended in the linea alba, and in a way recognized by all as furnishing a union of great strength. On the lateral portions of the ring where the tendon in front of the rectus becomes blended with the tendon behind that muscle so as to make thus a tendinous border entirely around the ring, the strength of the union of the aponeurotic layers is not so generally recognized.

It is only necessary to open the sheath of the rectus opposite the ring of an umbilical hernia to recognize the strength of the union of the two layers at that point, at least in the great majority of cases. There is in addition a practical point of importance in our efforts to cure in these cases. In some of them we will find that one or more attempts have been made to effect a cure by denudation and direct approximation, and in such cases the denudation or *excision* of the ring will have diminished or even removed portions of this line of union between the two layers of the sheath, but as the sutures are usually applied so as to include these two layers, the new borders will be brought together anteroposteriorly, and as the strain in that direction will be small the two layers will probably remain together and result in a new and firm union, though the lateral strain prove too great to permit a firm union with those layers approximated from opposite sides of the ring.

With this exposition of anatomic and operative points as a basis, I will select the first case in which I applied the plan to be described. That case is selected as illustrative for the reason that it presented all the conditions in which any usual procedure would with nearly absolute certainty result in failure to cure, and the additional reason that the lapse of time as a test of cure is the longest I can offer, and still further an event in the progress of the case furnished some evidence of the efficiency of the plan and a more recent event one of the sources of failure.

The patient, a woman, 34 years of age, was admitted to the hospital April 20, 1899. She had given birth to five children, three of whom are living. Nine years after the birth of her first child she discovered an umbilical hernia, also a right inguinal hernia. The inguinal hernia, I found, had been cured by an operation, but several operations had been executed on the umbilical hernia, each of which had promptly resulted in failure to cure. She reported seven operations on the umbilical hernia, and as five of them were ascertained to have been made, credit may be given to the statement that seven attempts to cure were made prior to the operation undertaken by me.

The patient having illness not associated with the hernia and attended with fever, operation was deferred until June 13, 1899.

On that day, when the patient was under the influence of an anesthetic, the hernia, which was about the bulk of a large-sized coconut, was found to have a ring somewhat larger than a silver dollar, readily receiving three fingers placed laterally.

It was then and for the first time apparent that adhesions of viscera to the sac prevented complete reduction.

A vertical incision was made directly into the sac, when the adhesions of bowel and omentum to the sac were found extensive, intricate, and in many places very firm. These adhesions were separated so far as to release the bowel from any probable source of obstruction, and the sac was dissected free from structures outside of it well to the aponeurotic margins of the ring, and a portion of the pouch was then excised, leaving enough in extent and of proper shape so that what remained could be closed by a whip-stitch along the median line without tension on the suture. No

FIG. 2.—From Sappey's Anatomy.

direct measure intended to approximate the borders of the ring was undertaken, nor could it have been accomplished without such tension as surely to defeat the attempt to cure.

In dissecting the sac free from the parts outside of it, there was left a large surface of the sheaths of the recti muscles more or less uncovered. Attention was now given to a thorough uncovering of those sheaths from all overlying portions of fat or loose connective tissue for a space sufficient for the subsequent procedure. Having thus secured a surface of tendinous structure in a condition to allow securing easy coaptation and good union, a longitudinal incision was made in the sheath of each muscle near the external border. (Fig. 2.) Each incision was probably slightly more than 5 inches in length, with the middle point opposite the center of the hernial ring. The anterior layer of the sheath was then separated mainly by blunt dissection from the underlying muscle well to the borders of the ring, and for sufficient distance vertically to allow turning the flaps thus formed inwards, so that coaptation could be secured without tension. The diagrams will illustrate

this better than verbal description. But little trouble was encountered in this procedure in effecting a separation at the lineae transversae, though an occasional strand of fibrous tissue required the careful use of the blunt scissors or scalpel.

That part of the dissection, however, needs to be made with care, the fascia being held under proper tension and sufficiently freed from blood to allow of full use of sight and touch in determining just what to do in order to secure an uninjured sheath of tendon. Between the transverse lines the sheath is free to any manipulation which the operator wishes to make after the vertical incision along the outer border is made. It seemed probable that sufficient sources of nutrition would remain to prevent death of any portion of this tendinous flap, *if no cross-incision were made*, and if tension through suturing were avoided, hence the flaps were made as long and broad as was practicable.

When the flaps were free they were turned to the middle line and sutured by the cobbler's stitch about $\frac{1}{4}$ inch from their free borders for a distance slightly in excess of the vertical extent of the ring, and then a

FIG. 3.—From Sappey's Anatomy.

loosely-placed whip-stitch was used to coaptate the free edges above the cobbler's stitch. (Fig. 3.) The folded and doubled portions of the flaps were then secured by somewhat loosely-placed interrupted sutures, placing a few of these stitches so as to fasten the flaps near the borders of the ring. These interrupted sutures were made to include as small portions of the tissues as possible, in order to reduce interference with nutrition to as small a degree as was practicable. The surfaces thus held by the interrupted sutures would not be under great strain, and, being broad and flat, coaptation could be secured without the probability of noteworthy tension on the sutures, even should vomiting occur. It seems probable that care in this part of the procedure will be necessary, in order to avoid serious interference with the nutrition of the flaps; but the tissues involved being constituted of strong elements, the sutures need include only such small portions as the dexterity of the operator will permit him to take.

The hernial ring having been closed in this way, the overlying skin was trimmed to proper dimensions and

proportions to allow closure without tension, when the skin and underlying tissues on the lateral portions of the wound were closed by running suture, to secure apposition and avoid "dead spaces" and the margins of the skin were closed by the use of a buried suture, kangaroo tendon being used in all the suturing. The wound was then sealed with collodion, and the waiting for the result was begun.

Nothing noteworthy occurred in the healing process, though the development of intercurrent illness 3 or 4 weeks after operation required that the woman should remain in bed longer than would otherwise be deemed necessary.

After the wound was closed I had noticed that some of the running stitches used to coaptate the skin to the underlying parts had penetrated so near the surface of the skin as to lead me to fear that they might become the means of infection, for experience had led me to believe that such infection could arise in two ways. In the first place the suture might penetrate a follicle containing a pus-forming bacillus, or, secondly, it might come so near to the surface that in the exfoliative changes or through attrition or abrasion just above the strand of suture it might be so exposed as to allow infection through contamination of the thread by external agents. The suspicious points, however, were so near the lateral portions of the field that my anxiety was not great, and as week after week passed without any sign of inflammation, all fear from that source subsided.

About the middle of August, however, signs of a mild inflammatory process were manifest at the seat of one of these offending stitches, but as it was evident that the bacillus was not of a virulent character, would tend to progress slowly, and sufficient time having elapsed to insure the thorough union of the tendinous structure, I allowed the process to continue several days before interference, but on August 19, *i. e.*, 2 months and 6 days after the operation, I opened the abscess. The suppurative process had proceeded along the subcutaneous suturing so as to separate the skin from the fascia and to explore the line where the two tendinous flaps had been joined, and I was pleased to note that the welding had become so complete that it was only by careful observation that I could discover where the coaptation had been made, the tendinous structures having blended into a continuous aponeurosis extending entirely over the space included in the former hernial ring.

It was several weeks before the abscess finally healed, but at no time has there been any sign of yielding at the site of the umbilicus, but when I saw the fascia at the bottom of the abscess it occurred to me that I had not been sufficiently careful in coaptating the reflected and underlying fascia below the ring where the strain would be the greatest.

In the description of the operation the fact that two silver sutures were found, one in each opposing margin of the ring, was omitted, but such was the case, and thus was added another instance in support of what seems to be a proper conclusion—that nonabsorbable sutures under strong tension are useless in operations for the cure of hernia, for here the tension had caused one stitch to cut through one margin of the ring, and the other through the opposite margin.

The operative procedure which I have endeavored to set forth is so far as I know a new one, for I have not been able to learn of its previous use, or description; but I have no pride in becoming the introducer of a novelty, and will feel no chagrin if I learn that I have

overlooked in our massive literature a similar story of surgical expedient.

Nor do I desire to take refuge behind a classification as a presidential address from any criticism of means or methods, but will gladly welcome any evidence which will show fault of technic, for thereby is the progress of medicine served, an object which should be more dear to each of us than the desire to be a discoverer.

THE GERM OF YELLOW FEVER.

BY LIEUTENANT COLONEL CHARLES SMART,

Deputy Surgeon-General U. S. Army.

THE identification of the germ of yellow fever has for the past twenty years been one of the principal objects of pathologic and bacteriologic investigators; for with the germ would be associated the antitoxin, the cure, and the prevention of this deadly disease. Truth is mighty and will prevail, but in medical matters its progress is slow. Those who have been laboring at this work know how little is effected by years of work and how many false steps have been made which have required years of patient research to remedy the evil and restore the *status quo*. Scientists, and medical scientists among the number, are generally and properly credited with an acceptance of new discoveries only when fully verified. The history of medicine fully illustrates this. The laboratory-workers have no reward before them except that which may come to them by virtue of earnest and good work truthfully recorded as throwing light upon causation, treatment, and prevention of disease. Occasionally a medical man scores a success in gaining a medal for a special essay on a particular subject. The money value is of no account, but the medical credit is great, and our young men aspire to be the recipients of such credit. This has a material value in the progress of medicine; but outside of this the rewards are only exceptional and appear to go by impulse and unscientific acceptance of asserted claims, rather than by well-considered results. Only in this way can we explain the \$10,000 award to Sanarelli for his claimed discovery of the germ of yellow fever—a discovery which had been asserted by half a dozen other workers in pathologic and bacteriologic fields before him. Four years ago Sanarelli announced the discovery of the germ of this disease, and this appeared to be accepted almost without question. Surgeon-General Sternberg, then at the International Medical Congress at Moscow, Russia, suggested that *Bacillus icteroides* of Sanarelli was no more the specific cause of yellow fever than his *Bacillus X*, which he recognized as resembling *Bacillus coli communis* in its morphology, although its pathogenic power was greater. Since his appointment as the head of the Medical Department of the United States Army, Surgeon-General Sternberg has been unable to make personal investigations in the bacteriologic laboratory, but fortunately his position has enabled him to suggest to other bacteriologists the line of work to be followed to bring forth the evidence on this important question. Drs. Reed and Carroll and Dr. Agramonte have followed up this question with the utmost care. The report of the former will soon be published in the *Journal of Experimental Medicine* (Johns Hopkins, Baltimore, Md.), while Dr. Agramonte's report has already been published in the *Medical News* (February 10 and 17, 1900). Agramonte's conclusions are that Sanarelli's *Bacillus icteroides* is no more concerned in

the production of yellow fever than are the common colon-bacilli which are frequently found in the blood and viscera of individuals suffering or dead from yellow fever. He isolated this bacillus from three cadavers in which death was not due to yellow fever. Reed and Carroll report Sternberg's *Bacillus X* as belonging to the colon group, and Sanarelli's *Bacillus icteroides* as a member of the hog-cholera group. We have seen a communication from Dr. Reed, under date of July 24, 1900, in which he states, in relation to the present outbreak of yellow fever at Pinar del Rio, Cuba: "Our laboratories are now in good working order. We have been able to study carefully seven cases since our arrival. Of these, one resulted in recovery (a severe case) and six were fatal. Neither during life nor after death have we been able to isolate *Bacillus icteroides*; but our sixth autopsy, which occurred day before yesterday, cannot be definitely reported upon as yet."

The July issue of the *Rivista d'Igiene e Sanità Pubblica*, published in Turin, contains a translation in Italian of Surgeon-General Sternberg's reply to Sanarelli, and in the same article is published a report of the researches made during the past two years by Dr. Adolphe Lutz, in the province of San Paulo, Brazil. Dr. Lutz, who is a corresponding member of the Academy of Medicine of Turin, is quite outspoken in his statements. The serum of Sanarelli has neither bactericidal nor antitoxic qualities for the bacillus used in producing it; and as regards the etiologic role, the bacillus cannot be found by known methods of research in more than half of the cases of yellow fever. He believes that those observers who report that they have found the bacillus in all cases, and that they can make the diagnosis by the agglutinating action of the blood, are the victims of gross errors of observation.

The details of these articles submitted beneath make it appear probable that the credit given to Sanarelli has been an assumption and that we have yet to learn what is the specific cause of yellow fever.

Letter from Dr. Adolphe Lutz on the Germ of Yellow Fever.*

SAN PAULO, January 12, 1900.

PROFESSOR PERRONCITO, *President of the Royal Academy of Medicine of Turin*.

In response to your request I send you a resumé of the researches made in my institute in 1898, which has just been printed. You will see that, in perfect accord with all unprejudiced observers, I consider that the serum of Sanarelli has not shown any favorable effect upon the sick who have been treated by this method. It is, besides, well known that its preventive action has completely failed in many cases in which the experiment has been made. I will say further that in our experiments made with the bacillus isolated at San Carlos, and recognized by Sanarelli as genuine, the serum has not succeeded in protecting the animals experimented upon against the effects of inoculation. When the cultures of San Carlos are tried with the serum of Sanarelli they are agglutinated in the proportion of 1 to 4,000, and even more. The bacillus does not develop in the pure serum, but mixed with one or two parts of bouillon it no longer prevents abundant development—only the bacillus grows agglutinated at the bottom of the tube, producing long chains very similar to those of the bacillus of Yersin. You can easily repeat this experiment, which was made by one of my assistants.

It results from all this—as I have already stated to a representative of the company manufacturing the serum—that this serum has neither bactericidal nor antitoxic power for

* Translated from the *Rivista d'Igiene e Sanità Pubblica*, Torino, 1^o Luglio 1900.

the bacillus used in producing it and that its employment should not be recommended.

As regards the etiologic role of the bacillus which was discovered and very well studied by Prof. Sanarelli, it seems to me that it is not entirely beyond doubt. Many epidemiologic facts accord very badly with the bacillary theory. The bacillus has never been found in an evident manner in the fresh tissues of 60 yellow fever cadavers which I have examined with the best staining methods. The blood, which is always sterile in the first part of the malady, rarely gives a frank agglutination. The bacillus cannot be found by known methods of research in more than half the cases. When it is present it is only obtained in rare colonies, the disease being characterized by the facility with which the organism is invaded by microbes which have nothing to do with the malady. It is possible that the presence of Sanarelli's bacillus is simply due to a secondary infection, which varies in frequency according to the season and locality at which the observation is made.

I have seen in the literature references to observers who found the bacillus in all cases and who believe they are able to make the diagnosis by the agglutinating action of the blood. But I am absolutely certain that their reports are the result of confusion and gross errors. If we admitted that the bacillus of Sanarelli is the cause of yellow fever there remains still much obscurity upon the transmission and mechanism of the malady; and certainly therapeutics has as yet gained nothing from this discovery. The prevention of the disease continues to be one of the most difficult tasks.

As corresponding member of the Academy of Medicine of Turin I feel myself obliged to make these declarations, as I have already done in my capacity as Director of the Bacteriological Institute, where the study of yellow fever has been carried on with much care during long years. Personally, I have seen more than 500 cases and about 100 autopsies, so that I am quite familiar with the malady. I have also visited 20 independent epidemic centers of the disease. If I have not published more upon this question it is because in my opinion it is still so far from being elucidated that it cannot be profitably discussed.

I terminate my letter with best wishes for the Academy and its members.

Very truly yours,

ADOLPHE LUTZ, M.D.

Reply to Sanarelli.*

By GEORGE M. STERNBERG, M.D., LL.D.,

Surgeon-General U. S. Army.

I SHALL not, at the present time, attempt to make a critical review of the evidence offered by Sanarelli in support of the specific etiologic relation of his *Bacillus icteroides*, nor to reply *in extenso* to his criticisms upon my previous communications relating to this subject. But in justice to myself I beg leave to call attention to the following facts:

In my paper read at the Twelfth International Medical Congress, and published in this journal (Band 22, No. 6-7), I did not make the positive claim that *Bacillus X* was identical with Sanarelli's, but gave reasons which led me to infer that this was the case. I say in this paper:

"Up to the present time the probability seems to be quite in favor of the view that Sanarelli's *Bacillus* is the same as my *Bacillus X*, and if this identity is not established the former can scarcely be the true cause of yellow fever, for I made in Havana, by the most approved methods, numerous cultures from yellow fever cadavers and carefully studied all bacteria found in these cultures. I *Bacillus icteroides* of Sanarelli was in the blood or in the tissues of yellow fever cases in Havana I certainly should have found it, for it grows readily in the culture-media used in my researches. But if it is not identical with my *Bacillus X* it was not present in the blood and tissues of the yellow fever cadavers which I studied in my extended researches in Havana. In the same paper I recognized my *Bacillus X* as being closely related to the colon-bacillus. I said:

"This bacillus resembles *Bacillus coli communis* (*Bacillus a*) in its morphology, although it is somewhat broader, and its colonies in gelatin roll-tubes are also quite similar,

especially so long as they are young. It is distinguished, however, from *Bacillus coli communis* by its pathogenic power when it is injected into the abdominal cavity of rabbits."

In my second paper (Band 22, No. 19), I say:

"In judging of cultural differences now existing it must be remembered that *Bacillus X* has been cultivated in artificial media for eight years. In the comparative study now being made in the pathological laboratory of the Army Medical Museum in this city, the peculiar seal-like colonies, to which Sanarelli attaches so much importance, have not been observed in cultures of *Bacillus X*. Again, *Bacillus X* causes gas-production in lactose bouillon, while Sanarelli's bacillus does so in less degree or not at all.

"In view of these facts identity in biologic characters can not be maintained.

"The next question which arises is whether the bacillus obtained by Sanarelli from yellow fever cadavers in Rio de Janeiro, and by me from yellow fever cadavers in Havana, are varieties of the same species. Comparative experiments are now being made under my direction with a view to determining this question.

"If *Bacillus X* and Sanarelli's *Bacillus icteroides* are not even varieties of the same species, the question will remain whether one, or the other, or neither, is concerned in the etiology of yellow fever."

In my third paper (Band 25, No. 13), I say:

"The experiments which have been made under my direction in the laboratory of the Army Medical Museum in this city (Washington) have convinced me that the bacillus of Sanarelli and my *Bacillus X* have permanent characters which distinguish one from the other and, consequently, that they are not varieties of a single pathogenic species. I am, therefore, obliged to admit that Sanarelli's researches give no support to the supposition, which for a time seemed to me to have a certain degree of probability, that my *Bacillus X* is the specific cause of yellow fever. On the other hand, my researches give no support to Sanarelli's claim. My *Bacillus X* was obtained by me, in small numbers, from about one half of the yellow fever cadavers examined by me in Havana. Sanarelli, using the same methods, found his bacillus in about the same proportion of cases and also, with one exception, in comparatively small numbers. Both bacilli are pathogenic for rabbits and guinea-pigs—Sanarelli's bacillus more so than my *Bacillus X*. But experiments upon these animals fail to give any satisfactory evidence that either bacillus is the specific cause of yellow fever. Both bacilli when injected into the circulation of dogs (5 cc.) produce vomiting, fever, a hemorrhagic gastroenteritis with bloody discharges from the bowels, albuminous urine, necrotic changes in the liver, collapse, and death in a certain proportion of the cases."

In a short reply to Sanarelli's paper published in the *Medical News* (December 9, 1899) I say:

"I gave some of my reasons in my article published in the *Medical News* of August 19, 1899, for maintaining a position of scientific conservatism as regards the etiologic role of Sanarelli's bacillus. His paper, which you are about to publish, adds nothing to the experimental data previously recorded, and, as I said in my paper above referred to, 'I have no time or inclination for controversial writing.' I have been unable to make any personal investigations since I was appointed Surgeon-General of the Army in 1893, but have followed with deep interest the researches of other investigators, and when the evidence is all in, hope to arrive at an unbiased opinion with reference to this important question. For the present I see no good reason for changing the opinion expressed at the conclusion of my previous communication, viz., that the etiologic relation of Sanarelli's bacillus has not yet been established. But, as I said in conclusion, 'if, however, the results reported by Drs. Reed and Carroll can be shown to be based upon erroneous observations, I shall be ready to revise my opinion. Truth is mighty, and no doubt in the end will prevail.'

"At some future time when the experimental evidence is all before us, I hope to make a critical review of the subject of yellow fever etiology, and if I arrive at the conclusion that the question has been definitely settled I shall be greatly pleased, for I am deeply interested in the advancement of scientific medicine. But the progress of science, in the past, has often been retarded by premature announce-

* Translated from *Centralblatt für Bakteriologie*, Bd xxvii, No. 20-21.

ments of discoveries, and by confirmation of alleged discoveries by prejudiced or incompetent investigators. A spirit of scientific conservatism is, therefore, very desirable if one would judge for himself of the merits of a question which can only be decided upon experimental evidence."

I have recently received detailed reports from Dr. Agramonte and from Drs. Reed and Carroll with reference to their latest experimental researches. Dr. Agramonte's report has been published in the *Medical News* (February 10 and February 17, 1900), and the report of Reed and Carroll will soon be published in the *Journal of Experimental Medicine* (Baltimore). Agramonte, as a result of his investigations made in the city of Havana during last summer, arrives at the following:

"2. *Bacillus ieteroides* of Sanarelli, lately (1897) asserted to be the causative agent of yellow fever, is no more concerned in the production of this disease than the common colon bacilli which are frequently found in the blood and viscera of individuals suffering or dead from yellow fever.

"3. When approved bacteriologic methods are employed, the bacillus of Sanarelli does not, as a rule, appear in cultures from the blood of yellow fever patients.

"4. *Bacillus ieteroides* may be and has been found present in the tissues of cadavers dead from other diseases, neither allied nor similar to yellow fever.

"5. The bacillus of Sanarelli, when subjected to agglutination tests, is not affected by the serum of yellow fever patients or convalescents.

"6. The serum of convalescent yellow fever cases affords absolutely no protection against infection by the bacillus of Sanarelli."

He says in his report:

"*Bacillus ieteroides* (Sanarelli). — *Bacillus ieteroides* occurred in 7 autopsies out of 23 (Nos. 5, 6, 10, 11, 15, 16, and 23), making an average of 30.43%. Its frequency in the organs was as follows: In cultures from the liver and heart-blood of No. 5; from the liver and spleen of No. 6; from the liver and kidney of No. 10; from the kidney, blood, and urine of No. 11; from the liver and pericardial fluid of No. 15; from the kidney of No. 16; from the liver and spleen of No. 23. Hence it will be seen that it was present in the liver of 5 cases, heart-blood of 2 cases, spleen of 2 cases, kidney of 3 cases, and pericardial fluid of 1 case."

With reference to *Bacillus X* he says:

"*Bacillus X* (Sternberg). — Associated with the *Bacillus coli* in a large number of cultures, its presence being recognized in some instance only after passing through guineapigs, was *Bacillus X* of Sternberg. This organism presented peculiar motility in some cultures, while in others it occurred as a nonmotile bacillus. It was classified principally from its pathogenic action on guineapigs, which, when inoculated with pure cultures of *Bacillus coli*, usually recovered; when these cultures contained *Bacillus X*, a fatal result was the rule. It became deprived of its motility with great readiness sometimes within a period of a few days."

Agramonte reports that he has isolated Sanarelli's bacillus from three cadavers in which death was not due to yellow fever. See his paper in the *Medical News* of February 10, 1900, p. 210-212.

The conclusions of Reed and Carroll are stated as follows:

1. *Bacillus X* (Sternberg) belongs to the colon group.

2. *Bacillus ieteroides* (Sanarelli) is a member of the hog-cholera group.

3. The various channels of infection, the duration of the disease, and the gross and microscopic lesions in mice, guineapigs, and rabbits are the same for *Bacillus ieteroides* and the hog-cholera bacillus.

4. The clinical symptoms and the lesions seen in dogs inoculated intravenously with *Bacillus ieteroides* are reproduced in these animals by infection with the hog-cholera bacillus.

5. *Bacillus ieteroides*, when fed to the domestic pig, causes fatal infection, accompanied by diphtheritic, necrotic and ulcerative lesions in the digestive tract, such as are seen in hogs when infected with the hog-cholera bacillus.

6. This disease may be acquired by exposing swine in pens already infected with *Bacillus ieteroides*, or by feeding them with the viscera of infected pigs.

7. Guineapigs may be immunized with sterilized cultures of *Bacillus ieteroides* against a fatal dose of the hog-cholera bacillus, and vice versa.

8. Rabbits may be rendered immune by gradually increasing doses of a living culture of *Bacillus ieteroides* of weak virulence against a fatal dose of a virulent culture of the hog-cholera bacillus.

9. The sera of animals immunized with *Bacillus ieteroides* and the hog-cholera bacillus show a marked reciprocal agglutinative reaction.

10. While the blood of yellow fever practically does not exercise an agglutinative reaction upon *Bacillus ieteroides*, the blood of hog-cholera agglutinates this bacillus in a more marked degree, thus pointing, we think, to the closer etiologic relationship of this bacillus to hog-cholera than to yellow fever.

REPORT OF A CASE OF TETANUS WITH RECOVERY.

By ANDREW H. WHITRIDGE, M.D.,

of Baltimore, Md.

The following case of tetanus occurred during my service at the Johns Hopkins Hospital in spring of 1899, and is interesting because the first symptom of the disease manifested itself on the thirteenth day, and 9 injections of tetanus antitoxin serum 10 cc. each were injected in the arms and thighs, followed apparently by no improvement. Morphia, $\frac{1}{2}$ grain, was given hypodermically every 4 hours, the dose being increased in a few days to $\frac{1}{4}$ grain, and showed most beneficial results in abating the spasms and irritability of the muscles. The patient made a perfect recovery and when seen one month after his discharge was entirely free from any tetanoid symptoms.

The patient was a young colored man, 28 years of age, a waiter by occupation, and was admitted to Johns Hopkins Hospital May 8, 1899, complaining of a burned foot. Family history was good, no tuberculosis, Bright's disease or insanity; personal history, had measles and no other diseases of youth. He always had been healthy. Eight years ago he had both feet badly frostbitten, and recovered with the loss of terminal phalanges of both feet. He had attacks of vertigo beginning five years ago which he claims was the result of an accident, falling three stories down an elevator shaft, striking his right forehead, after which he was unconscious for a few minutes, but soon got up and resumed his duties for that day, feeling perfectly well. Six months later the first attack of vertigo occurred. In these attacks he is dizzy and unconscious for a few seconds, but doesn't fall if he can catch hold of an object. These attacks come on during sleep. He denies that his muscles twitch before onset of vertigo, but has been told while he is talking with his friends he will suddenly begin to talk queerly and incoherently, and makes whining noises. He doesn't have any recollection of events during attacks, has never bitten his tongue, nor passed feces nor urine during a convulsion, and with the exception of present accident never injured himself. Such attacks come on three or four times in a year. He denies syphilis and gonorrhea; drinks only beer, not to excess.

Present illness: The accident occurred April 29, 1899, while the patient had an attack of vertigo. At the time of attack he was sleeping in a chair, and fell out and struck his foot against a red-hot stove burning the dorsum of the foot badly. The pain kept him awake that night, and he walked around room to get relief, not using any precautions to protect sole of foot from being infected. Next day he applied linseed oil and lime-water to the burnt surface and then noticed that his ankle was swollen, also that the glands in the right groin were swollen and tender. During this day he constantly kept his foot on the ground, and walked around the room with aid of a cane. Next day he went to bed and remained there until his admission to the surgical side. Four days after the accident, he noticed that the skin over the dorsal surface of the foot had changed from black to greenish-yellow, and a fetid discharge was oozing from the abrasions in the skin.

Physical examination. Temperature on admission 98.6°. Patient is exceedingly well built man; thorax symmetrical and well developed; lungs and heart negative on percussion

and auscultation. Urine negative, no albumin or sugar. Over right temporal bone there is a small linear scar and on palpation depression of temporal bone is noticed. Covering the dorsal surface of right foot there is an extensive sloughing area covered by a dirty greenish-white necrotic tissue extending from the toes to the end of the os calcis. The slough gives off an exceedingly offensive odor and the whole epidermis is entirely destroyed. In places areas of necrotic tissue were surrounded by granulation-tissue. The ankle was swollen but not the leg. The glands in the right groin large and tender. No evidence of syphilis on physical examination.

May 12, four days after the patient was admitted to my ward, which was 13 days after accident, I noticed some stiffness in the muscles of the face when opening his mouth, and some difficulty when swallowing liquids, it caused pain in his throat and neck. Thinking at this time he had caught cold, I ordered liniment for him so that he could have his muscles massaged. The symptoms remained the same during all that day, with temperature 98.4°, pulse 80.

On May 13 the patient could hardly open his mouth. There were slight spasms in the masseter muscle. The masseter contracted at will and became hard on attempting to open his mouth. He had some difficulty in swallowing, complained of pains through chest and back, and there was marked stiffness and rigidity of the cervical muscles. The patient was then transferred to a dark room, put on liquid diet and kept absolutely quiet. On May 14 he complained of pains through chest and face and neck, and marked rigidity of the cervical muscles; had characteristic cervical opisthotonos, also trismus. Mouth could be opened only 1 cm. He had great difficulty in swallowing. When passive irritation was made, he had risus sardonicus, which is well shown by the accompanying photograph. Facies has a peculiar appearance, with slight ptosis of right eyelid, deepening of the nasolabial fold, raised eyebrow and wrinkled forehead. When he swallowed cocoa this morning he was thrown into convulsions. I began giving nutritive enemata of peptonized milk, 4 fluidounces, albumen of two eggs every 4 hours; 10 cc. of tetanus antitoxin was injected into the arm, followed apparently by no good result. Patient in the afternoon had several convulsions, which began by contracting the muscles of the face, causing risus sardonicus, then invaded the deeper muscles of the neck, causing excruciating pain with cervical opisthotonos to such a degree that his occiput touched the thoracic vertebrae. During the spasm his trunk and limbs were perfectly rigid and he had severe pain through chest, with great difficulty in retaining his breath. This convulsion lasted four minutes. An eighth grain of morphia was injected which quieted him for three hours. The temperature reached 100°. After the spasm was over the patient was bathed in profuse sweat. In the afternoon the patient received a second serum injection and was ordered morphia $\frac{1}{4}$ grain every 4 hours. Efforts to talk caused spasm. On May 15 there was great difficulty in retaining nutritive enemata, and marked restlessness of the body. In the morning he had a convulsion lasting three minutes. He received the third injection of tetanus antitoxic serum and morphia was discontinued. The temperature was 98°, pulse 88. May 16 he had two convulsions in the morning lasting over five minutes, which began by contraction of the muscles of the face and arms, the whole body finally becoming rigid, and opisthotonos in marked degree existing, the patient being held as in a vise, and breathing with the greatest difficulty. During the convulsions he foamed at the mouth and was bathed in profuse sweat. Fourth injection of tetanus antitoxin was given and a slight improvement in the symptoms was seen after injection, the temperature being 98.8°, and pulse 100. May 17, morphia still discontinued. The patient had frequent and severe tetanoid contraction of the pectoral muscles, which ascended to the cervical group, and some contraction of the extensor muscle of the leg. Both biceps muscles were contracted. During the spasm the patient was almost asphyxiated and could not speak. The temperature was 100°, and pulse 120, with spasms coming on every two to three minutes. He appeared more sensitive to noise today than usual. On account of irritability of patient it was thought best to continue the morphia, a $\frac{1}{4}$ grain every four hours was ordered which was soon followed by diminished irritability of the muscles. The fifth injection

of serum was given in thigh in the afternoon, but there was no noticeable improvement of symptoms after injection. May 18, he had frequent clonic momentary convulsions during which there was slight arching of the back, and flexion and adduction of the arms with closure of the fingers; with effort mouth could be opened to slight extent. The recti abdominals and erector spinae muscles contracted forcibly on the slightest irritation. The muscles of the extremities are easily thrown into spasms at the slightest touch. On swallowing some cold water patient had a convulsion, followed by rigidity of the body. The temperature was 102°; pulse, 125. He had slight convulsions in the evening, which were controlled by using chloroform. May 19 the patient talked irrationally several times during the night; on swallowing some milk was thrown into convulsion. Nutritive enemata were discontinued, as he was unable to retain any of them on account of loss of control of the sphincter muscle. The temperature was 102° and pulse 120. He was very weak. May 20 was a very comfortable day, the spasms being less frequent and not so severe. The temperature was 100.6° and pulse 128; no convulsions. May 21: The patient's foot has been out of bath for past 3 days; spasms are not so frequent. The dose of morphia was reduced to $\frac{1}{4}$ grain. The temperature was 99.2°, and pulse 104. May 22: There is marked evidence of irritability of muscles of the arms, abdomen, and

spinal group, which contract readily on passive irritation. The muscles of the extremities are easily thrown into spasms at the slightest touch. The patient had spontaneous irritative attacks, interrupted with momentary convulsions which threw him into convulsions of partial opisthotonos, the buttocks, however, not raised. Trismus was still marked. The sixth injection of serum was given in the thigh. The temperature was 99.2°, pulse 104. May 24 the spasms were less frequent. The seventh injection of serum was given in the arm, but no improvement followed after injection. There was noticeable improvement after an injection of morphia. On May 25 the patient had frequent spasms, the cervical and abdominal muscles being contracted. He complained of pain through the thorax, and great difficulty in retaining his breath, which has been a constant symptom throughout his illness. Trismus was less, and he could open his mouth 1.5 cm. The eighth injection of tetanus antitoxin serum was given. On May 26 he received his ninth and last serum injection. Morphia, $\frac{1}{4}$ grain every 4 hours, was continued for 2 days. On May 29, after morphia had been discontinued for one day, the spasms became more frequent, the cervical and abdominal muscles being rigid. Having no serum on hand, $\frac{1}{4}$ grain doses of morphia were renewed, which was followed by very noticeable improvement in severity of spasms and wider separation between the attacks. The patient continued to improve slowly, getting up in the wheelchair on May 30 for a half hour. After May 30 he got up

daily in wheel-chair, although he complained of contraction of the cervical and abdominal muscles, with pain through the thorax and abdomen. He was now put on soft diet, causing no new symptoms nor any increased frequency of spasms. On June 14 he said he felt very comfortable, although he still had the facies which were present during the convulsions, deepening of the nasolabial fold, slight ptosis, raised eyebrow, and wrinkled forehead. His jaw could be opened 2.5 cm. There is still considerable rigidity of muscles of back and arm. Kernig's sign was present, and the patellar and deep reflexes were quite active. His chief complaint is of pain through the chest and in the hamstring muscle. Morphia has been discontinued since June 1. On July 5 the patient was discharged as cured.

At this time there was still some stiffness in muscles of the back, but he could open his mouth 4.5 cm. and masticate food readily without any difficulty. The only complaint he had when leaving hospital was sensation of tightness through the thorax and the existence of diarrhea, 5 or 6 stools a day. While in the hospital, he was treated for diarrhea, taking a lead-and-opium pill every four hours for three weeks. This was an oversight, as I thought I had ordered the nurse to discontinue them. At the end of two weeks from his discharge from the surgical side the patient returned to the hospital, complaining of a pain of colicky character in the abdomen with some gastrointestinal disturbances. He was admitted to the medical side, where they discovered he was suffering with lead colic. He had a distinct blue line at the junction of the gums with the teeth, also had colicky pains in abdomen. These symptoms soon disappeared under treatment. He had never worked in lead, and when leaving the hospital July 5 went directly to his home where he took one lead pill three times a day. I think I am safe in drawing my conclusion that he got his lead-poisoning from the pills which I ordered in the hospital. On May 18 when the spasms were most frequent, and his foot had been treated for 10 days, Dr. Harris made a bacteriologic examination of pits of tissue removed from slough. A mouse was inoculated and died of convulsions, but no tetanus-bacilli were found on cover slips or by cultures. The cultures proved to be of the bacillus of malignant edema and the *Bacillus aerogenes capsulatus* (Welch). Owing to the extensive surface which was covered by the slough there was only a mere chance that he got a bit of tissue in which the tetanus-bacilli had set up the infection, and on this account I feel confident if the area had not been so extensive we would have been able to isolate the tetanus-bacillus.

REPORT OF THE MILK COMMISSION OF THE PHILADELPHIA PEDIATRIC SOCIETY.*

THE Milk Commission of the Philadelphia Pediatric Society was appointed at a meeting held on January 10, 1899. Since then the Commission has made from time to time informal reports upon its work, but it has been unable to lay before the meeting any definite results until the present time. The reasons for this apparent delay are many. In the first place, the plan formulated by the Commission and approved by the Society differs in many respects from that adopted by other bodies, aiming at the improvement of the milk-supply for infants and for general consumption. So far as we have been able to find, there is no commission in any city with powers exactly similar to those with which

you have invested your Commission. Consequently, our plans had to be originated *de novo*, and consequently needed correction from time to time.

After consulting the available literature regarding similar work in other cities, and after considerable correspondence with those capable of giving the Commission information, the details of the plan were gradually evolved after many meetings and with repeated revision and corrections. After the general plan had been agreed upon, legal advice was sought as to our rights and powers, and in regard to what measures should be taken in order that successful applicants for our certificates might be protected from fraud upon the part of those not meeting our requirements. Numerous conferences were then held with various dairymen of approved standing, in order to determine whether our methods could be practically employed. It was not until these steps had been taken that the members of the Commission felt that their ideas were sufficiently well established to undertake the actual practical work devolving upon them. During the early spring of this year the Commission felt that it was prepared to offer to dairymen the opportunity for expert examination of their milk and cream. This was done by addressing printed circulars setting forth the objects and proposed methods of the Commission to a large number of milk producers. As a result of this many requests for information were received, and a considerable amount of correspondence was made necessary, especially in regard to the limit of fat in milk allowed by the Commission. The Commission heard the various suggestions made, and, while adhering to the essentials of their plan, made some slight modifications which they deemed advisable in order that the greatest number of infants should be benefited.

A summary of the articles of agreement with the dairymen is as follows: The Commission appoints experts to examine the dairy and its products in regard to the health of the cows, the cleanliness of the stables, milk-room and apparatus, and the health of the employes; also in regard to the chemical composition and purity of the milk, and the number and kinds of bacteria present. The Commission grants or refuses certificates in accordance with the result of the experts' examinations. These certificates are in such form that they can be handed to the consumer with each bottle of milk or cream. The dairyman agrees to abide by the decisions of the Commission and to pay for the examinations.

The procedures so far followed have been: First, that the agreements have been signed when the dairymen notified the Commission that they wished to have their dairy examined. The Commission, when so notified, instructs its experts to examine the dairy and its products. The experts then report to the Commission on blanks provided for that purpose, and, finally, where the examination has shown the proper conditions to be present certificates have been issued in accordance with the contract. So far the contracts have been signed by three dairies. The milk and cream of two of these have been found to attain to the standard set by the Commission. The other dairyman has so far failed to obtain a certificate, because the bacteria present in his milk exceeded in number the standard of 10,000 to the c.c.m. when it has been examined by the experts of the Commission. This dairyman is, however, we understand, sedulously endeavoring to improve his methods in order that he may obtain our certificate. We hear

* Read at the meeting of the Society, held October 9, 1900.

from reliable sources that other dairymen have failed to apply for contracts, finding through their own experts that they cannot as yet fulfil in all respects the requirements of the Commission.

Our accomplishment so far is that we now have in Philadelphia two dairymen producing typically good milk for infant feeding, while others are being stimulated to improve their dairies so as to enable them to obtain the certificate of the Commission. It does not seem too much to hope that ultimately the whole milk-supply of the city may be improved, owing to the demonstration of the practicability of such improvement and to the demand for certified good milk that will surely follow the education of the public.

At the present time but two dairies have applied for and been successful in obtaining the certificate of the Commission. These are the dairy of the Walker-Gordon Laboratory Company at Plainsboro, N. J., which comprises 177 cows, the center for distribution in the city being 1721½ Chestnut street, and the dairy of F. A. Wills, at Abrams, Pa., which is composed of 16 cows, the town office for distribution being at the corner of Berks and Camac streets.

With this report the Commission have brought for your inspection the various circulars, contracts, blanks for experts' reports and certificates which they are putting in use at the present time. All of which is respectfully submitted.

FREDERICK A. PACKARD, *Chairman*.

J. P. CROZER GRIFFITH.

ALFRED STENGEL.

THOMPSON S. WESTCOTT.

ALFRED HAND, JR., *Secretary*.

The standards adopted by the Commission and set forth in the contract are as follows: The bacteriologist's examination shall find the milk to be free from pus or injurious germs and have not more than 10,000 germs of any kind or kinds to the c.c.m. The chemical standards are a specific gravity of from 1.029 to 1.034, reaction neutral or faintly acid, not less than 3.5% to 4.5% proteid, 4% to 5% of sugar, not less than 3.5% to 4.5% fat (milk of a higher percentage to be so specified on each bottle); freedom from all contaminating foreign matter and from all additions of chemical substances or coloring matters; richness of cream in fat to be specified within 1% of the actual percentage; neither milk nor cream having been subjected to heat before the examination, nor at any time unless so announced to the consumer. The veterinary inspector examines "the cleanliness of the dairy in general, the care and cleanliness observed in milking, the care of the various utensils employed, the nature and quality of the food used, and all other matters of a hygienic nature bearing upon the health of the cows and the cleanliness of the milk, including as far as possible the inquiry into the health of the employes on and about the dairies; and . . . that the cows are free from tuberculosis or other diseases." These examinations are made approximately about once a month, without notice beforehand to the producer.

The report of the veterinarian concerns his examination:

- I. As to milking cows; hospital cows; dry cows; cows added since last report; cows in quarantine; cows recently calved; cows sick since last report. Total number of cows in herd, ———, of which ——— have been tested with tuberculin.
- II. Condition of milch cows.
- III. Food employed.

IV. Condition of stables; ventilation; heat; floors; troughs; cleanliness, etc.; dimensions of stables; condition of other buildings.

V. Health of employes and of their families, so far as ascertained.

VI. Source and character of water in dairy and stables.

VII. The general precautions of cleanliness in milking and the care of the milk are satisfactory

The report of the bacteriologist relates to the number of bacteria per c. c. of milk in each sample of milk obtained; pathogenic organisms or evidence of purulent inflammation of the udder; the sealing of the milk-bottles as prescribed by the commission etc.

The report of the chemist is as to the following results: Total solids (by evaporation of weighed amount in platinum basin); fat (Leffmann-Beam method); ash (by burning off solids obtained as above); total proteids (Kjeldahl-Gunning method, factor 6.25); preservatives and added color; specific gravity, etc.

ANGIONEUROTIC EDEMA OF THE SALIVARY GLANDS.¹

By JAMES ELY TALLEY, M.D.,

of Philadelphia.

MRS. A., 34 years, Irish American, has been under my observation for 5 years. During that time she has suffered twice from septicaemia due to retained membranes following neglected abortions, both probably due to a badly retroflexed uterus for the second of which she refused treatment; she also has a nephritis which dates from the first abortion. She is apparently unusually susceptible to poisons both microbic and medicinal, as the parenchymatous nephritis dates from the first attack of septicaemia, during which attack three douches of mercuric chlorid, 1:8000 produced a marked pyralism, and two grains of quinin on two separate occasions produced a widespread and intense urticaria-like eruption with much subdermal edema. She had had a similar experience with quinin years before.

Three years ago the patient had her first attack of general urticaria which was hemorrhagic, and since then she has rarely been free more than a week or so at a time from hives. The rash varies from a few patches to a general profuse eruption, with here and there one that is hemorrhagic. She is always dermatographic. Since the development of the nephritis 5 years ago, she has had 4 profuse hemorrhages, 2 nasal and 2 uterine. For two years she has suffered occasionally from nocturnal asthma.

At intervals of 7 years—thus antedating the nephritis and the first attack of urticaria—she has complained of spells of a peculiar swelling at the angle of the jaw, but it is only recently that I saw her in an attack and was able to determine their character. Two hours after the beginning of the attack the submaxillary and sublingual glands were enormously swollen and very tender. The parotids were apparently not so largely involved, though the lower part of these glands were also somewhat larger than normal.

These attacks come on every few months and reappear each morning from 7 to 8 o'clock for several days in succession. They begin with a "tickling in the ear and throat, a drawing of the tongue," pain and rapid swelling of the glands, which reaches its maximum in about 15 minutes, and is immediately followed by a profuse flow of saliva, which begins with a sensation as of "many little blisters bursting under the tongue," returning to normal in from 3 to 24 hours. The sensation of many blisters bursting is interesting when one remembers that the submaxillary gland discharges by one, and the sublingual by many ducts beneath the tongue.

At first this condition was always confined to the right side, but recently both sides are involved in the attack, which alarmed the patient and caused her to seek advice during an attack.

These spells are preceded by nausea, much belching and gastric distress, but no colic. So far as can be determined, neither the parents, nor brothers or sisters have had any such trouble. There has been no hemoglobinuria, nor do the attacks have any relation to the menses.

¹ Read before the College of Physicians, May 2, 1900.

The character of the swelling, the rapidity of its development, the lack of any evidence of salivary calculi, the preceding gastric distress and periodicity, especially when occurring in one who is so subject to urticaria and so dermatographic, would seem to indicate a case of angioneurotic edema of the salivary glands.

The points of special interest are that the salivary glands are involved rather than the lips, the labia or some other common seat of election, and that the secondary paresis of the vessels producing a hyperemia increases tremendously for a time the function of the glands, as shown by the outpouring of saliva.

TWO NEW PIECES OF LABORATORY APPARATUS: PETRI DISH FORCEPS; EXHIBITION TEST-TUBE STAND.

By RANDLE C. ROSENBERGER,
of Philadelphia.

Demonstrator of Bacteriology and Morbid Anatomy.

From the Laboratories of Jefferson Medical College Hospital.

WHEN a worker in the laboratory has a good many bacteria to study, and also a large number of plates to make, the rapid sterilizing of his Petri dishes is a question of moment. Or, when there is hurry, and a plate is to be made in a few minutes, rapid sterilization of the Petri dish again engages his attention.

To obviate the necessity of waiting from one-half to one hour for the sterilization of the Petri dishes in a

Petri dish forceps, showing a dish in the grasp of the forceps. Reduced to about one-third size. Drawing made by Mr. Philip A. Sheaff.

hot-air oven (which is the ideal method of sterilization), a pair of forceps has been devised, to facilitate instantaneous sterilization thereof. One pair of forceps grasps the upper dish and one pair grasps the lower. The forceps are made of heavy brass wire, have a good strong spring, and there is no fear of dropping the dish, when once in their grasp.

The dishes are now passed alternately through the bunsen flame, "inside downward," so the inside of the dish is sterilized by direct action of the heat. This maneuver repeated 8 to 10 times moderately slowly sterilizes thoroughly; the lower dish is laid on the table and the upper dish dropped over it.

This method of sterilization may also be resorted to when the worker has not access to a hot-air sterilizer. There is no danger of breaking the dishes if ordinary care is taken. The cut will illustrate how the dish is manipulated with the forceps.

The second apparatus consists of a modified test-tube rack, or, better, test-tube stand. It consists of a wooden base with depressions to hold the bottom of test-tube steady. Above (instead of the ordinary perforated wooden apparatus), and supported on each end, is a heavy brass wire, with spaces which exactly fit the test-tube. On the posterior portion of the stand are inserted 2 coils of wire, one at each end, between which a card can be inserted of any color.

This stand was at first intended to be one for the demonstration of chromogenic bacteria alone. The colored cardboards show off any particular colors of growth, and this can be more conveniently passed around a class or audience than the old wooden stands.

Test-tube stand, showing cardboard in the coil at the posterior portion of the stand, and one tube showing the ring in the albumin test. Reduced to about one-quarter. Drawing by Mr. Philip A. Sheaff.

Upon second thought, it will be of use to the general practitioner who examines urine in his office. By placing a black cardboard in the coil, he can perform several tests for albumin at the same time, simply placing the tubes in the stand and going ahead with others. This will do away with holding up of the test-tube against the coat sleeve, to get the typic white ring at the line of contact in Heller's and Roberts' tests for albumin.

Again, it is a much neater apparatus and a less bulky one than the old wooden stand. The illustration will demonstrate the apparatus probably better than I can describe it.

I wish to extend my thanks to Chas. Lentz & Sons, who so kindly aided me in the perfection of both these pieces of apparatus. Also, I owe my thanks to Mr. Philip Sheaff, undergraduate at Jefferson Medical College, for his kindness in making the illustrations for this article.

**The Biennial Congress of Scandinavian Physi-
cians** met recently in Copenhagen. It was voted to publish a report of the proceedings in the *Nordisk Medicinisk Archiv* in the German language, as it was said that papers and abstracts published in French or English were more or less neglected by the foreign press, while those in German were much more likely to receive notice. The next congress will be held in 1902, at Helsingfors, under the presidency of Professor Runeberg.—[*Medical Record*.]

VOL. VI, No. 17

OCTOBER 27, 1900

\$3.00 PER ANNUM

The Etiology of Yellow Fever.—It is with exceptional pleasure that we lay before our readers in the present issue the most noteworthy paper of Dr. Reed and his coworkers upon the role of *Culex fasciata* Fabr. as the intermediate host of the germ of yellow fever.

Research in medicine has achieved in the last quarter of a century many important results. New stand-points and points of departure rivalled only by the doctrine of cellular pathology have, within the two or three decades now closing, arisen with startling rapidity. The demonstration of the germ-origin of disease, with its immediate application in antiseptic surgery and more remote result in the antitoxin mode of treatment, stands unrivalled in beneficent influence and fertility by any previous performance in medicine, and challenges the most important discoveries in art and science in its benign effect upon the progress of the human race. The space extending between Pasteur's historic researches on pébrine and charbon to the discovery of the long host of specific disease-germs now known to medicine is short in point of time but long in respect to results achieved. Today we stand on the threshold—perhaps indeed we may be considered to have passed that barrier—of the solution of the portal of entry into the human and animal body of the germs causing a group of blood-infections whose origin hitherto has been one of the dark chapters in medicine. It is now twenty years since Laveran's discovery of the malarial parasite in man. Great as has been the progress in diagnosis and treatment following his discovery, the mode of the origin of the infection and its prevention have received no explanation. With the discovery of the role of the mosquito in propagating and carrying the infectious agent, now no longer to be doubted, the next to the last chapter in the epidemiology of malarial fever in man has been completed. There still remains the problem, the solution of which is assured, of removing the offending anopheles from the environment of man, or of depriving it of infected blood-corpuscles as food.

That insects carry infectious agents is an old belief. Theobald Smith, in this country, had previously shown that the cattle-tick is responsible for the direct transmission of the organism of Texas fever of cattle. The relation of the mosquito-filariasis first pointed out by Bancroft and Manson has not only been confirmed, but through the recent studies of Low has been extended to

include the direct inoculability of the parasite into the blood of man! The list of disease-germs, whose portal of entry into the body has remained obscure, includes yellow fever. There has been, and there will continue to be, much skepticism with regard to the Sanarelli bacillus. If the observations of Major Reed are confirmed, even though the specific germ of yellow fever be not immediately discovered, there shall have been shed upon this most fatal disease a new flood of light that will lead to greater restrictions of its ravages and, perhaps, eventually its elimination from our Southern shores. All honor is due to the brave men who voluntarily submitted to the test of inoculation! That one, in his ardor to serve science and his fellow-men, should have succumbed to the experiment is one of those sad tragedies that the records of the art of medicine, no less than those of war, have only too frequently to note. Such an act of self-sacrifice will not be permitted to pass unrecognized and unrewarded. "Greater love hath no man than this, that he lay down his life for his friend."

Parasitic Hemoptysis.—Dr. Charles Wardell Stiles, zoologist of the Bureau of Animal Industry, presented at the last meeting of the Medical Society, District of Columbia, an outline of an interesting Government report he now has in press, regarding a parasitic hemoptysis in Asia, which has been introduced into this country. He called special attention to the fact that our troops returning from their Eastern service will bring a number of diseases home with them which are not common in this country. Among these maladies he referred especially to uncinariosis, filarial elephantiasis, parasitic hemoptysis, and probably Cochin-China diarrhea.

The parasitic hemoptysis has already been introduced, probably either by returning missionaries or Chinese laundrymen. Ward reported one case in the cat in Michigan in 1894, and Kellicott one case in the dog the same year.

Both Ward and Stiles at that time prophesied that the disease would probably spread. This prophesy has been fully verified, for the Bureau of Animal Industry has recently found over 50 cases in hogs in Ohio, and Dr. Stiles is of the opinion that the disease has probably spread to man, but has been confounded with tuberculosis. He states that it may first be expected

among the farming classes. The disease is due to a parasitic trematode worm, *Paragonimus Westermanii*, and is common to man, hogs, dogs, cats, and tigers. Ordinarily only the lungs are infected, in which nodules are found. Usually two parasites are encysted together in each nodule. Coughing and spitting of blood are the prominent symptoms. Diagnosis is made by finding the oval eggs in the fresh sputum by microscopic examination.

Occasionally the parasites or their eggs gain access to the brain, in which event Jacksonian (cortical) epilepsy results. There is no specific treatment, but patients may recover by being sent to noninfected areas. Dr. Stiles' article on the disease covers about 50 pages and treats of the disease from the zoologic, sanitary, and medical standpoints. It is illustrated with text-figures and plates, and includes full synonymy and bibliography, together with a complete review of the entire literature. It will appear in about two weeks as a part of the annual report of the Bureau of Animal Industry, U. S. Department of Agriculture.

A Grave Charge.—What appears on its face to be a grave charge is made by the *Philadelphia Press* of the 21st of October. This newspaper, after inspecting the examination papers of recent applicants for license to practise in this State, charges that thirty of these papers were regraded after the original grade had been placed upon them by the State Examining Board. In all these instances the grades had been raised high enough to allow the candidates to pass, although they had been graded below the required average by the Board. The *Press* does not hesitate to imply that the Medical Board has not been able to resist "pressure," and that this pressure has been brought to bear not only by politicians, but also by medical colleges, professors, benefactors, and kinsfolks of the unsuccessful candidates. The instances printed by the *Press* show that the averages were raised in cases in which the candidates failed by only a few points, to gain the requisite grade of 75. Thus one applicant had a grade of 72.14; another a grade of 68.85.

The charge implied in the editorial comment of the *Press*, that the State Examining Board is subject to "pressure," is a very ugly one, and should not be allowed to go unanswered. Possibly, as one member of the Board has stated in an interview, it is the custom of the Board itself to revise the papers of candidates who fail by a very few points, and to regrade them so as to give a higher average if this appears proper to the Board collectively. Such a revision and regrading by the Board itself before pronouncing its final decision in such cases may be clearly within its prerogative. A candidate who fails by an average of 74.50, possibly by reason of an exceptionally low grade in only one branch, might well deserve a careful reconsideration of his case before being finally rejected on such a narrow margin.

As we have already said, the implied charge of fraud should be met by the Board. We must know whether this is really a fraud or only a mare's nest.

The "Hall of Fame" farce should give an excellent subject for some opera bouffe writer. It is plain that the judges have not been chosen for their fitness, have not taken their work seriously, have not been guided by a high and dignified ideal, but have been ruled by class prejudices, local prides, and fantastic superficiality. They have thought of the word famous as indicating the person the most talked about, most read, or that has happened to get himself before the popular attention. Hardly one judge seems to have asked himself who has best deserved fame, not one has inquired who has done the most good to his fellow men. The name of no woman is thought worthy of a place.

Then consider the blundering crudity itself of wishing for a "Hall of Fame." The affair can have but one effect, that is, to inspire the young and ambitious to secure fame by the same means as these famous men have done. But the ethics, the religion of all noble action is not to seek to do that which will bring human applause and renown, but that which will be right, prevent evil, and better human life.

Not a physician is to have his name in the New York Hall of Fame,—and it is a matter of congratulation! And yet there have been a thousand physicians who have done a thousand times more good to their fellow men than many that are likely to be included, for instance, Edgar Allen Poe or Daniel Boone.

Newspaper Notoriety.—Some physicians seem to be born newspaper doctors; some achieve this sort of greatness; and some do undoubtedly have it thrust upon them. It is sometimes hard to decide in which class a man belongs, but there is a growing conviction on the part of the profession that, when a man's exploits, operations, health, goings and comings, his opinions on medical subjects, etc., appear habitually, and for years in the papers, sure it is, despite his protests, by his wish and will. As we know to our disgust, many newspaper reporters have not a spark of honor, and their promises are made in order to be broken. Not all, however, are liars. Still it is best never to talk with them. Even if they are honest they are usually incapable of reporting any professional thing correctly. When a medical fact or a physician's opinion goes through a newspaper office, it generally comes out a sorry mixture of untruth, error, and distortion. To a man of character and scientific attainment, a sprawling interview, or an account of an operation in reportorial English, with photograph to prove it, is a most harmful and deplorable thing. That it may be wholly without his consent and against his desire we know from a recent instance of which several correspondents complain. That it may

be schemed for, we know in another case in which the advertiser fearing his portrait might not be asked for, or that an old stereotype might be used, spontaneously sent his most recent photograph to the "City Editor." It is so easy to stop the whole procedure if one sincerely wishes to stop it, that, as we have said, when it continues a long time, we may be sure the "correspondents" do not wish the abuse to cease. We have found the great majority of editors and city editors of newspapers have no desire to disobey a simple written request by a physician that in no case is his name to appear in the paper without his written consent. The few wretched sensational papers that refuse to act upon such requests may be ignored. Why do not those opposed to the practice have their medical societies pass a resolution to that effect and transmit it to the newspapers with a list of the members? There seems to be a deal of useless botheration and exaggerated difficulty in checking a folly that persists because it is secretly desired, and because a simple request is not made.

The Definition of the Words, "Ptomain and Toxin."—A correspondent with reason complains that there is a lack of clearness in the definitions given by textbooks and dictionaries of the words *Toxin* and *Ptomain*. As others may also have noticed the fact we append definitions which seem to give the distinctions:

Ptomain (πτῶμα, corpse). A basic nitrogenous compound, resembling the alkaloids, produced by the action of bacteria on organic matter. As they are usually formed in putrefactive processes, ptomains have also been termed putrefactive alkaloids. Some are poisonous, many are not.

Toxin (τοξικόν, poison). 1. Any poisonous nitrogenous compound produced by animal or vegetable cells. 2. Any poisonous substance, proteid in nature, produced by animal or vegetable cells; also called toxalbumin.

The true nature of the latter is unknown; although most of them give the reactions of albumoses or other proteid bodies, they have never been isolated in a free state. They are uncrystallizable, are soluble in water, are dialyzable, and are destroyed by heat. Some of them behave as if they were of a ferment or enzyme nature.

Toxin, animal.—One produced by the metabolic activity of animal cells, as snake-venom.

Toxin, bacterial.—One produced by the metabolic activity of bacteria, as diphtheria-toxin.

Toxin, extracellular.—A bacterial toxin elaborated by a microorganism and thrown off into the surrounding medium. The majority of the best known toxins are extracellular.

Toxin, intracellular.—A bacterial toxin contained in the bodies of the bacteria themselves.

Toxin, vegetable.—1. Any toxin produced by vegetable cells. 2. Specifically, one produced by higher plants, as ricin (produced by the castor-oil plant), abrin (produced by the jequirity plant).

The Duty of the Public to Itself.—The Philadelphia Press, which, in its editorial utterances at least, often stands for good ethics and common sense in medical matters, has again been prodding the medical profession to be up and doing to suppress quackery and illegal practice in this State. The Press seems to think that the burden of this work should fall upon physicians, since, from its point of view, they are the ones

most directly interested in abolishing christian scientists and all other charlatans. While we do not aim in this JOURNAL to absolve the medical profession in the slightest degree from any of its public duties, we think it worth while to point out that the public itself, and not the profession, is more nearly interested in this matter. It is the public, and even sometimes the more intelligent portion of it, that is responsible for the prevalence of quackery, and pays the price for it. Not physicians, but the people, are they who sacrifice health and life to this modern juggernaut. It is not our children, but theirs, who thus suffer and die. The medical profession is never weary of proclaiming this truth, and of doing what it can to avert its consequences, even though in so doing it is usually accused of acting from selfish motives and purely to protect its trade interests. The first duty of an enlightened and liberal profession is doubtless to instruct the public, but it is not so obviously its duty to do police work to protect that same obstinate public from itself, or to lobby in the State Legislature for repressive legislation. It has never shrunk, however, from taking a hand even in these matters, but it is not willing to let the lay press put upon it the entire onus of the responsibility for suppressing organized quackery. When all lay journals, not only in their editorial but also in their advertising pages, recognize fully their own responsibility to the public in this matter—when, in other words, they lead a crusade against charlatans and refuse at the same time to advertise their wares, they will be in an admirable position to recommend a policy to the medical profession.

Only recently it was reported that the Governor of New Hampshire met Mrs. Eddy in state at the public fair grounds, where this false prophetess was received by the city and State authorities, and escorted by a troop of mounted police and a mounted aid from the Governor's own staff. Will the Press kindly tell us whether it is the duty of the medical profession in New Hampshire to repress the Governor of the State? He evidently should be repressed by somebody.

Increase in Juvenile Crime.—Mr. Franklin Matthews, in a paper just published in *Harper's Weekly*, seeks to prove that there has been a large increase in juvenile crime in New York City in recent years. Mr. Matthews asserts that the records of that city are, from political motives, kept so imperfectly that it is difficult to compile accurate statistics, but he claims that he has access to a private record which shows that the number of arrests of youths for robbing has increased enormously. A few years ago it was rare to find more than four or five youths, under twenty-one, in the Tombs at one time, awaiting trial for burglary or grand larceny, but recently almost two-thirds of the boys awaiting trial are charged with these crimes. The ratio is about 15 out of 25—or 60%. In one week there were 36

boys in the Tombs awaiting trial, of whom 22 were charged with burglary, 7 with grand larceny, and only 5 with misdemeanors. The rate of increase in thievery among juveniles is, according to Mr. Matthews, simply appalling. This increase is largely in the East side of the city. One boy was arrested six times in eight months for stealing. Mr. Matthews does not hesitate to charge that the present political conditions in New York are largely responsible for this prevalence of crime. He even intimates that the police are in collusion with these delinquents, and gives an instance in which an overcoat that was stolen could not be recovered until money was paid for it.

Children are heavy sufferers in other ways, according to Mr. Matthews, from the political depravity of the metropolis. Little children are put on exhibition for shocking displays in some of the saloons, and the most inhuman and depraved crimes against children, of a quite unmentionable character, are prevalent. From the standpoint of social science it may be too much to hold the administration of any large city wholly responsible for the prevalence of any form of crime, but Mr. Matthews' indictment against the government of New York is a very terrible one. He shows at least that something is lacking in the present administration of the metropolis since such a state of things can exist.

In favorable contrast with this report from New York is the statement which comes from Chicago about the working of the Juvenile Court in that city. This is a tribunal that takes cognizance especially of juvenile delinquents and attempts to rescue and reform children instead of graduating them in crime. The journal known as *Charities*, for October 6th, has a paper on this subject in which it shows the efficient working of this Court. This tribunal is devoted to saving children, and it seems to be effecting its object in innumerable instances. A similar court both in New York and in Philadelphia would be a godsend to these cities.

Vascular Changes in the Eye in Connection With Albuminuria.—An ophthalmoscopic examination will sometimes detect vascular changes in the eye indicative of what may be called the prealbuminuric stage of albuminuria. In such cases the general fibrosis of the arteries and accompanying high tension has not proceeded to such an extent as to cause extensive kidney disease, with consequent albuminuria, although progressive vascular changes may be noted in the fundus oculi. The first account of the changes found by the ophthalmoscope in cases of high arterial tension was given by Mr. Marcus Gunn in a brief note in 1892,¹ which was followed by a longer paper in 1898. Recently the subject of albuminuric retinitis is taken up, and illustrated by case reports, by H. B. Grimsdale,² who also refers to Gunn's papers.

In the prealbuminuric cases the arterial reflex is narrow and bright, compared by Gunn to a bright copper wire, and the whole artery is of a lighter color. It is seldom that the coats are sufficiently thickened to be much visible, not infrequently the indication of coats at the disc can be traced in cases of high tension for some considerable distance beyond the margin, and very occasionally distinct white lines along the edge of the blood-column show the presence of greatly altered and thickened coats.

The most characteristic of these early signs of high tension is, as Gunn points out, afforded at the crossing of veins by arteries. In the earliest cases the vein appears to be pushed back by the artery into the retina, and as a result the light reflex is lost for a short distance on each side of the crossing, because the surface of the vein no longer lies in a plane at right angles to the incident light. In a later stage the vein seems pushed on one side by the artery in the direction of the flow of blood in the latter. In still later stages the vein is more obstructed by the artery, and appears much narrowed where the crossing occurs. The distal portion of the vein is larger than the proximal, owing, no doubt, to the partial damming of the flow by the hard artery which lies across it.

With this condition there are often to be seen hemorrhages in the retina, either superficial and tracking in amongst the nerve-fibers, the so-called "flame-shaped" hemorrhages, or deeper in the molecular and nuclear layers, the "glandular" hemorrhages. In both these cases the outlines of the hemorrhages are irregular, and their extent is small. A less usual form is very much larger, and has a perfectly sharp outline, approximately semicircular below, and bounded by a straight line above. These were called D-shaped or "subhyaloid" hemorrhages, as it was thought that here alone would the extravasations of blood track with sufficient freedom to maintain such sharp margins. Actual anatomical examination has shown that this is not the case, and the blood may be in the retina. In no instance has the blood ever proved to be really subhyaloid, *i. e.*, between the retina and the hyaloid membrane.

Vision is as a rule not greatly affected by the hemorrhages. Even if they occur at the macula the thin layer of blood is to some extent transparent, and a considerable fraction of vision may persist, though objects are spoken of as "seen through a red veil" in many cases. This symptom may very well give rise to the suspicion of hemorrhage, but it must be remembered that hemorrhage is not the only cause of erythropsia. However, if the effused blood sets up a retinitis, vision may be seriously impaired, and if the general condition is not properly treated there is danger of relapses, which, however, though leaving large spots of degeneration in the retina, may have surprisingly little permanent effect on the visual acuity.

Less commonly, in connection with albuminuria

¹ Transactions of the Ophthalmological Society, 17, K., 1892.

² *Treatment*, London.

apart from the changes which have been described, disease of the walls of the veins results in thrombosis of the central retinal vein or one of its larger branches. This gives rise to a formidable fundus-picture not easily forgotten, and as the retinal elements are seriously damaged, vision is greatly reduced. Hemorrhages may also occur into the optic nerve behind the globe, giving rise to a form of retrobulbar neuritis, with much less striking ophthalmoscopic evidences.

The prognosis of albuminuric retinitis is very grave. Few patients live over two years. So long as the changes are slight and there are no hemorrhages, we have no reason to suspect that the vessels in the brain are more diseased, and may regard the chance of their giving way as not very great. There is, however, no certainty about this, as the vessels of the brain are not necessarily at the same stage of the disease as those of the retina. The presence of great change and of multiple hemorrhages gives rise to a much graver prognosis, and we must regard the probability of cerebral hemorrhages as not remote. Obviously, any cause likely to increase the local arterial pressure must be avoided, and all measures taken to keep this pressure within or below normal limits.

The Overcrowded Medical Profession.—In common with the other professions, that of medicine is overcrowded. This condition is not a new one, but it is worse than it was and it is continually growing worse. We doubt whether it is within the province of any man to point out a sure and certain remedy for bad sociologic conditions; but it is within the province of any of us to note a few of the factors that contribute to existing evils and by avoiding them in the future to lessen to some extent the evils of which we complain.

Medicine invites the allegiance of many who imagine that they see in its practice an easy method of making a respectable living without going to much expense in preparation. This class was especially appealed to by the formerly existing short courses of study with the absolute certainty of graduation at the end of two years. To-day, being shut out of most reputable medical colleges, the same class is taking up the various branches of quackery, such as osteopathy, hypnotism, christian science, and kindred short cuts to good incomes. The "institutes" of various kinds which now advertise instruction in the various "healing" fads make a special point of dilating upon the certainty of making a good living by these means in a very short time. It is evident that a "good living" for these frauds is a smaller annual income than is requisite for the reputable physician with his necessarily large expenditures every year for books, instruments and remedies. The fact that these charlatans have come and have come to stay, should be recognized. We cannot lessen the evil, no matter how much we deplore it. Irregular practitioners of various sorts now monopolize more than half of the

medical practice in regard to minor illnesses—the kind that would eventually get well without treatment or in spite of it—and which formerly contributed a very respectable annual sum to the average doctor's income. The genuine medical profession still does as much work as ever in serious diseases, but gets less pay for it.

It may thus be seen that even without an annual influx of new men, there is less work today for the average doctor than there was twenty years ago. Preventive medicine is still further lessening the amount of routine work for the general practitioner. Typhoid fever was formerly the standby for steady income in many communities. Four or five cases of that disease continually on hand made a very fair bulk of the general practitioner's outside work. The prevalence of this illness is constantly decreasing; some day it will be practically eradicated. So it is with diphtheria; so it is in some parts of the country with malarial diseases. Altruistic medicine is lessening its own work and diminishing its own income.

With these and kindred facts in mind, is there not some legitimate way to lessen the number of doctors who have to do the work? Should not every physician and especially every college professor, do his best to keep the incompetent, the ne'er-do-wells and certain failures from entering our ranks? No young man should be encouraged to take up the study of medicine unless he possesses natural qualifications of an exceptionally high order. Good drug clerks, good barbers, good carpenters, and good school teachers should not be urged to abandon occupations for which they are suited and in which they make probably as fair an income as they will make in medicine for at least ten years. Every professor in some colleges feels that it is duty to secure at least one student each year for the class; sometimes he goes out into the highways and byways and compels them to come in. Only too often the recruits thus obtained are neither desirable from the standpoint of intelligence nor pleasant associates from the standpoint of personal character.

We plead for more care in the selection of medical students; we plead for less enthusiasm in urging young men to take up the study of a science for whose practice their personal qualifications do not fit them; we plead for a less crowded profession by raising the standards of admission into that profession.

A Warning Concerning a Man Representing Himself as Our Agent.—The Business Manager of the PHILADELPHIA MEDICAL JOURNAL requests us to warn physicians, especially in New England, concerning a man named Dr. J. Steinberg. At one time he was an authorized subscription agent of the JOURNAL, but was dismissed because he did not report collections he had made. He is still continuing this practice. Physicians will confer a favor by telegraphing us where the man may be found.

Correspondence.

A VISIT TO THE FINSEN INSTITUTE.

By GEO. G. HOPKINS, M.D.,
of Brooklyn, N. Y.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE Finsen Institute, which I have come all this distance to see, is one of the most interesting clinics I have ever at-

FIG. 1.

tended. At present Prof. Finsen has under treatment about 200 cases. These cases are of all forms of lupus, from very mild to the most severe. The accommodations are somewhat limited and they can only treat 16 patients at a time, by electric light, and by the sun about 12. The sun-treatment is by a lens, 8 inches in diameter, fitted into a band of metal closed on the other side by a plain piece of glass, making a chamber which is filled with water colored with sulfate of copper. The sun lenses are of glass, not rock crystal, as are the lenses used with the electric light.

FIG. 2.

I was most fortunate at my first visit (though I considered myself very unfortunate), in finding the Crown Prince Frederick there looking over the cases. I sent in my card to Dr. Finsen, and prepared for a long stand. But the doctor asked if I might be presented, to which the Prince very graciously assented and invited me to accompany him in his inspection. My good fortune was in the fact that the Prince speaks perfect English and Dr. Finsen does not understand any.

For more than an hour we inspected 50 or 60 cases, and he translated my questions and gave me the answers.

My results at home were very encouraging, but the results here indicate that this treatment is certainly one of greatest of medical discoveries of the century just closing. The most difficult cases to treat are those that come during adolescence, from 15 to 22 years of age. All proliferation, they claim, is more active during this period than at any other period of life, and therefore the disease advances much more rapidly.

FIG. 3.

In children it is very speedily eradicated. After 30 years of age, with each decade, the response to treatment is the more rapid. Patients that have been subjected to cureting respond to the treatment very slowly.

I inclose with this the photographs of 5 unpublished cases which Dr. Finsen very kindly gave me. There are two pictures of each case, showing the condition before and after treatment.

No. 1.—The patient came under treatment April 1, 1896.

FIG. 4.

and was discharged cured April 6, 1899. She had 55 sun treatments and 151 electric light treatments.

No. 2.—This patient came under treatment April 6, 1899, was discharged cured June 16, 1900. She had 145 electric light treatments and 34 sun treatments.

No. 3.—Treatment began August 22, 1898; the date of discharge was mislaid. She had 53 sun treatments, and 175 electric light treatments.

No. 4.—Treatment was begun January 10, 1900; patient was discharged cured June 29, 1900. She received 126 electric light treatments. No sun treatments.

No. 5.—Treatment began January 19, 1900; the patient was discharged cured March 25, 1900.

The strange feature of these cases is that they are largely women. Among the hundred and more cases that I saw in the several days I was at the institute, there were probably not more than ten men, and these were all young men. There was a uniform improvement in every case that I saw under treatment.

FIG. 5.

The Government is constructing a more commodious building for the institute. It is really what we term a free dispensary. Dr. Finsen is now turning his attention to the treatment of such cancers as can be reached by the knife, and afterwards by the light. I saw one case of a large fungating cancer of the neck at least 5 inches in diameter. The photograph represented it in appearance like a large sunflower. This was removed by the knife, and the base treated with the decomposed light, and the patient has as healthy a cicatricial tissue, where the growth was removed, as could be asked for. I examined it carefully and believe that he has accomplished a cure in this case.

THE METHOD OF TEACHING PHYSIOLOGY.

By JOHN C. CARDWELL, M.D.,

Instructor in Physiology in the Long Island College Hospital, Brooklyn, N. Y.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

MANY of the ideas expressed in an article recently published in this JOURNAL so nearly accord with my own, some of which were put into practice during last college year, that I am anxious to express my appreciation of that article.¹ The mass of scientific knowledge concerning the phenomena intimately associated with living matter and living things which is called physiology, has accumulated as the result of observation, experimentation and reasoning. Why not use the same means in the teaching of it? Why not at least direct and encourage the student of medicine to acquire his basis-knowledge of it by these means?

As Prof. Porter reminds us, "physiology deals with phenomena, not with words." And it is only by the actual observation of these phenomena that the facts of physiology can really be acquired. The teacher who describes, or en-

deavors to describe, these phenomena is not imparting to his pupils a knowledge of them, but rather his own conception, or interpretation, of them, which has itself been derived, in small part, perhaps, from individual observation, but largely from the writings of others who may or may not have actually observed the phenomena of which they write. "Too often in our medical schools," writes Prof. Porter, "information is mistaken for knowledge." This remark is full of truth and significance. Not many decades ago most of the courses in physiology given in the medical schools of this country consisted of didactic lectures "illustrated" by an occasional experiment. The idea of introducing an experiment in order to "illustrate" some remark or assertion of the lecturer seems strange indeed—inasmuch as his *very* assertions have been directly or indirectly derived from observation and experiment. The order and proportions should be reversed; the facts of the science should be presented to the student by means of experiments, and the remarks of the lecturer confined to the grouping, discussion, and interpretation of these facts.

An experiment shown in the usual manner during the course of a lecture does not bear its full value. The student should see each experiment from beginning to end; should, in fact, in every instance in which it is practicable, personally conduct it—under the supervision of course of an instructor who has himself performed it over and over again. He should not be told what to expect, but required to record what he sees, hears, feels, or in any way becomes cognizant of. From such observations his data should be constructed—his matter-of-fact knowledge obtained. The experiments should be selected and arranged in such serial sequence that, as the groups of facts accumulate, the student is naturally led—with but little assistance from his instructor—to derive from them those inferences which constitute the minor generalizations of the science. He should be encouraged not merely to observe, but to reason for himself upon what he observes.

From what little experience I have had in the practical use of this method I am able to say that in some departments of physiology at least it can be actually carried out. Having thus acquired some real knowledge of his subject the student is prepared to listen to, or read, what others have learned about it, and to grasp the broader conceptions, hypotheses and theories of physiology. In this the instructor can give substantial aid, by performing for him experiments too difficult for him to conduct or requiring special apparatus, and by bringing together scattered points of evidence or such data as have been derived from experiments which require more time in their carrying out than can be afforded in the course.

If this method is followed the student gains a more or less adequate conception of "fact," "generalization," "hypothesis," and "theory," as these terms are used by students of science, and of their relative values and interrelations; he becomes familiar with many of the methods used in the study of the phenomena of living things; he learns to appreciate the greater knowledge-value of what he himself observes as compared with what he is told, or reads; and while at work he is cultivating a mental habit which will prove of far greater value to him and to others with whom he may as a practitioner or teacher have to do, than will any amount of mere "information" taken at the word of his instructor. In the course of his work, too, he will come upon points that have not been completely worked out, or face to face with unsolved problems, and in this way will gain some conception

¹ Porter, Wm. Townsend, PHILADELPHIA MEDICAL JOURNAL, Vol. vi, 379-84.

of the borderland and present limits, of physiology. Not only is this method valuable as a means of mental training—a point which Professor Porter justly accentuates—but it is also, I think, more valuable than the methods in vogue as a means of acquiring a substantial knowledge of physiology—such a knowledge as can be turned to account in the actual practice of medicine. The fact that physiology is one of the fundamental branches of medical science must not be lost sight of in the teaching of it.

The method should be followed not only in our colleges and medical schools, but in high schools and academies as well—wherever, in fact, physiology is taught.

In the very lowest grades—of even our public schools—many facts of physiology could be learned by simple observation of living animals without resort to vivisection, and even in the intermediate and higher grades, much could be taught by the same simple means. In the colleges and medical schools, vivisection is, of course, quite indispensable. Not only in the teaching of physiology is the method commendable, but also in the teaching of physics, chemistry, pharmacology,—indeed, any of the branches of physical science. It is a matter of prime importance that all students, of whatever age, be impressed with the fact that, however useful books may be as aids in the acquirement of knowledge, that sort of knowledge of the objects and phenomena about us which goes by the name of natural science is not directly obtainable from books.

The method itself is not essentially new. Many men of science have long admitted its value, and, in greater or less degree, applied its principles in their teaching, yet it has not been universally or even generally adopted.

Let us hope that Prof. Porter's able exposition of it, and the care with which it has been developed and applied at the Harvard Medical School will encourage other teachers to give it fair trial.

553 Halsey Street, October 6, 1900.

THE INJECTION METHOD OF TREATING INTERNAL HEMORRHOIDS.

By R. D. MASON, M.D.,

of Omaha, Neb.

Professor of Rectal Surgery in the Creighton Medical College.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

AFTER reading an article in your JOURNAL of September 24, 1900, on "Hemorrhoids, Etiology, Pathology, and Treatment," I cannot refrain from adding a few words in defence of the injection-method. The author says:

"I am grieved to say that it still finds advocates among men whose medical education should be a guarantee of intelligence." Also that "sloughing and great destruction of tissue are perfectly natural consequences, and fistulas, abscesses, and strictures are common results, while violent hemorrhage, pyemia, and death are not rare."

Now, while I agree with the sentiments of most of the paper, I believe the foregoing statements are too radical. I have made a special study of rectal diseases for the past 10 years and I think that I am endowed with at least ordinary intelligence, and I am sure there are cases in which this method is not only useful, but the best that can be devised. Four years ago I read a paper before the Medical Society of the Missouri Valley in which I took the ground that this method was suitable in "well-selected cases," which I described in the following words. I have since had no reason to change my opinion:

"Patients suffering from internal hemorrhoids do not, as a rule, consult a physician until the tumors have been formed for some time. They may have existed for a long time before their presence is known by the patient; but after an unusual amount of exertion or a protracted period of constipation or too liberal indulgence in food or spirituous beverages they suddenly begin to protrude at stool. Now when this occurs they will nearly always be highly irritated and in a badly inflamed condition. Should the sufferer come to you at this time he would not be a suitable subject for the injection-plan of treatment. But most of these cases buy some patent medicine to use until the acute exacerbation is over and then go along pretty comfortably until another attack occurs, and each one proves a little worse than the one which preceded it until the tumors get so they protrude at each stool. They generally remain more or less irritated and sore with the sphincter muscle highly sensitive. But occasionally, in a case of long standing, they will lose their soreness and the constant friction and congestion will induce an induration of the tumor-wall with a plastic exudation into the connective tissue between the different coats of the bowel and a somewhat hard semifibrous tumor is the result. The constant protrusion of these tumors causes the sphincter to lose to a considerable degree its contractile power and they protrude very easily. The sphincter also loses its sensitiveness and tendency to spasmodic contraction which is so painful. In many of these cases the tumors are out of the body most of the time. These are the ones that are suited to the injection-plan of treatment."

I will describe a typical case which is only one of many that I have treated.

Mr. H., a farmer, aged 50, had suffered from piles for several years. He easily forced into view several large solid tumors. There was no pain or soreness of any kind. The sphincter was greatly relaxed and the tumors were cut most of the time. I will not ask space to describe treatment except to say that I used a 50% solution of carbolic acid. He never complained of a particle of pain or inconvenience and was not confined to his bed an hour because of treatment. Those tumors have not been seen or heard from since, although this was 5 years ago.

I have patients under observation who were treated eight years ago and I have never had one patient in whom there was a return of the disease. I have had patients return for further treatment after a year or more, for this reason: When one or two tumors have been treated they feel that they are well, and although assured that there are more that need treatment they often will not submit to further treatment, with the result that six months or a year later these tumors begin to show and there is an apparent return of the disease. This is not a return of the piles, but is simply due to the fact that the tumors were not all operated upon. A patient may of course have a return of his piles after a few years have passed even if operated upon by the ligature, although this does not usually occur.

As to the dangers described I admit that there are some things that cannot be foretold to a certainty, but they are of a minor character. The first is pain. This is sometimes more severe than expected, although seldom more than a few doses of morphia are required. This is often, in fact generally, needed in ligature or clamp operations. Second, there is occasionally sloughing and a discharge of pus, although this is very rare indeed. Third. We cannot tell positively just how long it will take to effect a cure. These are objections, I admit, but there are objections to all operations, and when it is remembered that this operation is generally done in old persons who cannot take a general anesthetic the objections raised are really of minor importance. As for fistulas and abscess I do not believe the danger is worth considering.

The author states that "violent hemorrhage, pyemia, and death are not rare." I have never heard of an in-

stance in which any of these things occurred, and if this author will kindly give the name of a reputable surgeon who has had them occur it will be a favor not only to me but to the profession. I am taking it for granted that this is done only by men who know how and not by persons to whom it has been *farmed* out. I know that when this method first became known there were many accidents as reported by Andrews, but this was by inexperienced men, and the same is true of any new procedure. The first operations for the radical cure of hernia were nearly all failures, now they are nearly all successful. So it is not fair to compare this method as now done by reputable physicians with results obtained ten or even five years ago. My only object in writing this is to place this treatment before the profession in its proper place, and show that there is *some* good in it. I think it has a field of usefulness, although a very limited one, and that in certain cases where a general anesthetic would not be safe it may be used with the happiest results. I have used this treatment I believe more than one hundred times and with only the best results except in a few of my earliest patients, where it was used in improper cases and even in these with no serious result. Neither do I believe that there is any more danger of serious result if done by a competent person than in using the ligature. Some of our leading surgeons have lost patients when operating with the ligature, and only recently I saw a bad stricture caused by the clamp and cautery done by one of our very first surgeons. Within the past three months I nearly lost a patient from hemorrhage following an operation for fistula. These accidents may and do occur in any operation and with the very best surgeons, but is this any reason why the operation should be abandoned? My operations for hemorrhoids are nearly all done with the ligature and I consider it the ideal method, although but little if any better than the clamp and cautery, but because I prefer these methods I am not ready to entirely condemn the injection method.

PRESERVATIVE INJECTION FOR THE EMBALMING OF HUMAN BODIES.

By A. HEWSON, M.D.,
of Philadelphia.

Demonstrator of Anatomy, Jefferson Medical College.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I DESIRE to call the attention of the profession to a preservative injection which I have used for several years and which is the outcome of investigation carried on in the mortuary of the Jefferson Medical College. The system as used is based upon the fact that the body can be filled to repletion by use of two gallons and a half of this fluid; there are of course variations more or less according to the height and weight of the body. It has been the effort to present anatomical material to the student in as lifelike a condition as possible, and in order to further this condition the various schools have instituted from time to time various processes, the last being the cold storage, which in every instance it was found necessary to accompany by the use, first, of a preservative. The pathologists have also in the Keiserling fluid endeavored to present pathological conditions in as near the condition found immediately after death as possible. This fluid, from my experience, does all and more than that done by the Keiserling solutions and merely requires immersion of the specimen, as the brain, for instance, therein. The parts are slightly hardened but retain their normal color perfectly.

The process is very simple and merely requires in the preservation of the entire body that an artery be opened and the fluid injected. When there is a large amount of blood, as in death from an acute disease, it is best to empty the venous channels. This is simply done by allowing the contents of the veins to run out.

The fluid is as follows: Sodium arsenate, 2 kilos (equivalent to $4\frac{1}{2}$ pounds) is dissolved in 7,850 cc. of boiling water. The arsenate is dissolved by boiling, or a saturated solution is made, as sodium arsenate is soluble in a proportion of 1 to 4 with cold water and very soluble in boiling water. When this solution is made, and even while hot, 2,000 cc. of pure glycerin is added to help hold the arsenate in solution, and also to make soft the body when embalmed.

Finally there is added from 100 to 150 cc. of formaldehyd. The solution is now allowed to cool and the excess of sodium arsenate is precipitated.

All bodies injected with this fluid are preserved in the usual manner, by being thoroughly greased, covered with paper, and then bandaged and placed in cold storage, at a temperature not exceeding 25°. The first effect of this injection is to render the mucous membrane more lifelike, the skin becomes red as in life, and the whole appearance of the body changes within 15 minutes. In the next 24 hours, if there is an excess of formaldehyd, as when 200 cc. was used, there would appear upon the face a darkened condition mixed with the red already described.

On opening the body the student finds the parts are just as they existed in life, in color and consistency. The brain, however, should be removed as soon as possible and placed in the fluid and allowed to remain three or four weeks, or sometimes less, according to its condition at the time of preservation. It will be in good order, with its color perfect, the consistency slightly hardened. If, however, specimens in bulk, as organs, are to be preserved, they can be immersed in the fluid and will retain their natural color and consistency, the latter depending upon the viscous.

I can recommend this fluid most heartily, as in my hands, when injected into the body by hydrostatic pressure, it has given the most thorough satisfaction. Hewson's solution:

R.—Sodium arsenate.....	2 kilo.
Aq. bul.	7,850 cc.
Boil until complete solution, then add	
Glycerin.....	2,000 cc.
Formaldehyd.....	100 to 150 cc.

CAN A COAL-MINER SELECT HIS DOCTOR?

By BAYARD HOLMES, M.D.,
of Chicago.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

It is perhaps worth while for the medical profession to consider one of the causes of complaint put forth by the striking coal-miners of Pennsylvania. Among other things they demand the privilege of selecting their own doctors. If medicine is to remain a profession, the medical man must be paid, if paid at all, by his patient. If he is paid by anyone else, he considers the interests of his paymaster rather than the interests of his patient. This is illustrated by a conversation which I once had with a Sunday-school superintendent, the son of a missionary, who had formerly been claim-agent for an international railroad entering St. Paul. This pious moralist claimed to be well acquainted with medicine and medical practice, and among other things he remarked that his railroad management found it advantageous to transport all of their surgical cases injured along the line to St. Paul, to

be treated in the hospitals there, as the recoveries were fewer than when treated without transportation, the maximum claim in case of death being \$5,000, while the claim for damage in the case of injury and recovery was practically unlimited.

Many corporations require their physicians and surgeons to act as confidential claim-agents and detectives, whose principal duty is to obtain evidence for the law department, and whose secondary duties are of a medical and surgical nature. It is unnecessary to illustrate this fact, which has become notorious in the experience of every reputable surgeon and practitioner. Natural selection under such circumstances as these provides railway companies, factories, and mining companies with men suited to their work. It is a case of survival of the fittest—i. e., the meanest. It would not be difficult for anyone acquainted with "company doctors" to find some noteworthy exceptions to this rule. Some of these men are not only thoroughly equipped, but they work with a spirit which is worthy of the commendation of the profession. Such instances, however, are not the rule, and from the very nature of the case they cannot be. The best of men can scarcely survive the pernicious influence of the claim department, and the unnatural relation to their patients which corporate interests require. It is one and the same demand that the striking miners make when they ask that they be allowed to select their own storekeeper and escape the truck-store, and choose their own doctor and escape the espionage of the company doctor. In this last demand they ought to receive the united support of the medical profession, but up to this time the writer has failed to notice any action favoring this demand of the strikers voiced by any medical journal or any medical society. Ought we not to come out and say that the dearest interests of medicine require freedom in selecting the medical attendant, and that the accident of being an employe ought not to interfere.

In the not very distant future I believe a struggle will be made in the representative medical societies to exclude with the osteopaths and christian scientists, the club doctor, and the company doctor. If this is not done, and if medicine is commercialized by their habits, customs and overpowering influence, then our profession sinks to a trade lower than the barber's from which it sprung. The natural consequence will be compensation in proportion to the honor in which the medical man is held. Now with high educational and social standing and a code of ethics far eclipsing that of the lawyer or the minister in the manner in which it is observed, the economic position of the doctor is all that can be asked for. He lives as well as his neighbors whom he serves. If the profession sinks to business standards none but a quack can survive. The doctor will be paid for his attention no better than the barber and the masseur.

This process has already begun. The larger life-insurance companies are getting their examinations made for \$1.50 down to 60 cents each, and many manufacturing concerns are paying 50 cents to 25 cents for prescriptions or dressings for their employees. Even the contractors of such public works as the Chicago Drainage Canal had scandalous medical and surgical service, and sent scurvy and wound-infection into the County Hospital to be cared for at public charge. The conditions under which "hired-men doctors" must do their work removes them from all personal responsibility or obligation as professional men. With the osteopath the advertising hernia and varicocele doctor, the spectacle doctor, and Indian doctor, the company doctor ought to take his place wholly outside scientific, professional medical society.

BATHING BABIES.

By J. FRED. CLARKE, A.M., M.D.,

of Fairfield, Iowa.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I HAVE a neighbor who has 8 children ranging in age from 2 to 16 years. Since the birth of the first child, except in the capacity of an obstetrician, this mother has not had a doctor in the house a dozen times to treat the children, and then only for scarlet fever, tonsillitis, or some such complaint. The children are all strong and types of healthfulness. They as babies are not merely fat, but the muscles are firm and well developed. Their complexions are excellent and they all have quiet dispositions, not being at all nervous or quarrelsome. I have carefully observed the family and I believe the chief factor in this remarkable record of good health, aside from the mother's ability to nurse the babies and her sensible ideas about food, lies in her art of bathing the children. From the age of two weeks to two years, Mrs. L. gives her baby each morning a cool bath with massage in the following manner: With the baby on her lap in a warm room, she sits by a bowl of tepid water and uncovering one part (a limb or the chest or back) at a time she dips her hand in the water (and with no soap), thoroughly wets the baby's skin and then gives it a vigorous rubbing with her hand until it is nearly dry, finishing with a Turkish towel.

The water applied is cool, the time spent at the bath is from one half to one hour. The skin after the massage is in a glow and the baby always, immediately after the bath, falls into a refreshing sleep. These baths delight the babies. They never cry and seem to thoroughly enjoy the whole process. Mrs. L. assures me that if for any reason she is unable to bathe the child for a few days, she notices a difference in the firmness of the muscles. "The muscles become flabby." Once a week she gives the children a hot bath with soap.

A visiting mother with a baby not at all strong allowed Mrs. L. to bathe her child for a week and I saw in 8 days a marked improvement in this child's condition.

Incidentally I learned from Mrs. L. that her children frequently go two, three, and often six days without a bowel movement. The health never seems to suffer and, without treatment, the bowels finally move naturally and without pain. The mother is not at all worried at these times and rarely gives her babies a laxative. I feel confident from my observations that the cool baths with massage have a most excellent effect on children before the age when active exercise is possible, for before a baby learns to walk, its movements are not such as to give it good general exercise. It also seems probable that the common constant use of laxatives with children is to be condemned. It is a very common practice for mothers to give laxative syrups almost daily to their children.

Foreign University Intelligence.—Adjunct Professor Oeller, of Munich, has been appointed full professor of ophthalmology and director of the eye hospital at Erlangen. Dr. Samson Gemmell has been appointed professor of clinical medicine at Glasgow University.

The Shah of Persia, while in Budapest, is reported to have consulted an eminent specialist, and was informed that he was affected with heart disease, and that the condition of his kidneys would grow serious, unless strict dieting was observed. The Shah remarked that he had consulted four doctors in France, three in England, several in Austria, and one in Germany, and that not one of them had told him the truth as to his condition.

Society Report.

NEW YORK STATE MEDICAL ASSOCIATION.

THE seventeenth annual meeting of this Association was held in the Academy of Medicine, New York, on the 15th inst., and three following days, the president, Dr. E. D. Ferguson, of Troy, occupying the chair. The first day was devoted entirely to executive business.

SECOND DAY'S PROCEEDINGS.

Upon calling the Association to order, the president took occasion to state that it was their good fortune to be visited by Sir James Grant, of Ottawa, Canada, and that it was an honor to introduce so distinguished a practitioner from over the border.

SIR JAMES GRANT was received with hearty applause. He accounted for his presence in a way that at the outset seemed political. "I have come to New York," he said "in the interests of annexation. In fact, my son is about to annex in marriage one of the fairest of the daughters of your city, and this will be but one more tie added to the many strong ones which already knit me to the United States." In a brief address he spoke of his investigations recently reported in Canadian and English medical journals into the nature of muscular rheumatism. This, he had proved to his own satisfaction, is no more than the manifestation of abnormal electricity in the body. If this fact is recognized and treatment followed in conformity therewith, the muscular rheumatism can be got rid of in 5 or 6 minutes, instead of as many months. He has found that the use of ten or a dozen fine No. 8 needles, piercing the muscle-tissue, will serve to discharge the surplus electricity, the muscles become soft and pliable and the pain vanishes.

The president's address was published in full in the PHILADELPHIA MEDICAL JOURNAL of last week.

DR. F. H. WIGGIN, for the Committee on Arrangements, of which he was chairman, reported in detail the plans which had been formulated for the entertainment of the members. Owing to the enforced absence of Dr. Alvin A. Hubbell, of Erie County, his paper on the *Relation of migrain to epilepsy*, was read by title.

DR. A. DROCKWELL, of New York City, read a paper on the *Analogy between nervous conductivity and electric conductivity and their relation to functional neuroses*. To compare nerve current and electric current it is necessary to become familiar with the coherer used in wireless telegraphy. When the neurons are studied in the light of this analogy, the most striking resemblances are discovered, and a new explanation of many of the neuroses is seen. SIR JAMES GRANT discussed this paper which he characterized in the most complimentary terms. As a healthy neuron differs from a diseased neuron, it is found that electricity, to be of value, must be applied before the stage of paralysis is reached.

Cocainism was the subject of a paper by DR. THOMAS D. CROTHERS, of Hartford. After comment upon its prevalence and rapid increase, he said of the addiction to cocaine, that it is characterized in its habitues by mental exaltation, great volubility of words without point or purpose, and without logical conclusion, the style being smooth and continuous; this may be recognized in fiction, poetry, and even in medical journal articles; there is frequently a mania for the writing of many letters. The conclusion of the paper was a warning against the use of cocaine under circumstances which might lead to the formation of the habit.

DR. JAMES J. WALSH, of New York City, finding the end of the session close at hand, gave a rapid recapitulation of the more salient points of his paper on *Heart complications in rheumatism*. He gave a digest of the more important conclusions on the subject, which were presented at the International Medical Congress in Paris.

Symposium on Obstetrics.—The afternoon session was devoted to a symposium on obstetrics. It was opened by PROFESSOR EDWARD P. DAVIS, of Philadelphia, who read a paper on the treatment of the patient during the weeks preceding the expected confinement. He emphasized the importance of examining the different organs and also the urine and solid excreta. The diet should also be carefully

attended to. It should be largely a milk diet. Tea and coffee should be avoided. Alcohol was not indicated, but on the contrary was likely to be injurious. Fruit should be stewed or baked. The body should be regularly sponged, the residence kept well aired, and gentle exercise taken in the open air. In cases of insomnia it was a mistake to give bromids; chloral or some derivative from it gave the best result. It was well to catheterize the patient under some circumstances under an anesthetic. In looking for sepsis, the possibility of syphilis should not be overlooked, and this also applied to gonorrheal affections; when traces of either of these diseases were discovered they should be treated locally as well as constitutionally. DR. AUSTIN FLINT, JR., of New York, followed with a paper in which he discussed the *Management of labor*, including the use of forceps. The proper management of these cases, he said, was more far reaching in its importance than the mismanagement of a few abnormal cases. Statistics showed a gratifying improvement in the success with which these cases were treated, and it was found that the less interference of any kind that was practised the less was the percentage of accidents. He advocated the careful examination of the patient at the end of the eighth month with the view of avoiding septic conditions. It was better to make one long and complete examination than a series of short ones. Undue delay in completing the delivery was almost as dangerous as undue haste. It was better in many cases to use forceps than to wait too long. The third paper was by DR. GEORGE W. JARMAN, of New York, and dealt with the *After-treatment of the mother in normal cases*, while the fourth, by DR. BERNARD COHEN, of Erie County, referred to the *Treatment of the child*. DR. JOHN E. WEEKS, of New York, described the *Pathology, prophylaxis, and treatment of ophthalmia neonatorum*, quoting statistics to show the large percentage of children whose eyes were affected by the gonococcus of Neisser or other bacteria, for the treatment of which it was usual to use a solution of silver nitrate. DR. EDWARD REYNOLDS, of Boston, discussed the *Major obstetrical operations* from the standpoint of a general practitioner, calling attention to the great advances that had been made in this branch of surgery, and maintaining that general practitioners must either get into the way of performing them themselves, or be prepared to call in an expert when a major operation appeared to be desirable. DR. WM. R. R. PRYOR, of New York, brought the symposium to a close by reading a paper on *puerperal sepsis*, its pathology and treatment.

A *symposium on the blood* engaged the attention of the association at an evening session, DR. EDWARD K. DUNHAM, of New York, dealing with the *Technic of blood-examination*; PROFESSOR JOSEPH C. BLOODGOOD, of Johns Hopkins University, with *Leukocytosis*; PROFESSOR ALFRED STENGEL, of the University of Pennsylvania, with *Pernicious anemia*; PROFESSOR C. Y. WHITE, of Philadelphia, with *Leukemia*; DR. T. LE WALD, of New York, with *Parasites in the blood*; and DR. C. H. GORDINIER, of Rensselaer County, with the *Value of blood-examination in the diagnosis of trichinosis*.

THIRD DAY'S PROCEEDINGS.

Necessity for Further Organization on the Part of Medical Men.—DR. C. A. L. READ, President of the American Medical Association, being introduced by the chairman, was received with applause. He said he accepted the cordial greeting as a mark of fealty to their great national association. He had peculiar pleasure in meeting the members of the New York State Medical Association because he discovered in their charter a proclamation of principles which appealed to him with particular force. These principles were the cultivation of their humane science, and the promotion of an *esprit de corps* among its members, the maintenance of the honor and character of the profession. Were not these sufficient to commend the organization to the enthusiastic regard of every practitioner in the great Empire State? They had also provisions of a beneficiary character which he understood they were holding under consideration, and which must appeal to every man who had a sympathetic bosom and understood the mutability of fortune. It was the irony of experience that he who needed succor was often the Samaritan himself. This feature of their organization might well be imitated by every State organization in the country.

On the present occasion, however, it was the fourth plank in their platform that particularly interested him. He referred to that plank which announced as one of their fundamental principles, the promotion of harmony, or, as the charter had it, "the establishment and furtherance of cordial professional relations and fellowship between the medical profession of the State of New York and the medical profession of other States of the United States and of foreign countries through the medical associations and societies of such States and countries." Criticism of this clause must exhaust itself in commendation. It breathed the spirit of harmony. That spirit of harmony was abroad in the profession, not alone in the State of New York, but the country over. This clause, if it meant anything, as it assuredly did, meant the union of their local profession. This clause meant that every member of their State organization should become a member of the American Medical Association, and he was delighted to know that already many bore that relation. If it meant anything, it meant, as it should mean, that they stood consecrated to the idea, over and above all other ideas, of the unity and solidarity of their great national profession. He knew of no object more worthy of their zealous devotion. It simply meant that this movement was one on their part that would command the cordial cooperation of the great national body of the profession, not only as represented by the American Medical Association, but of the great independent portion of the profession as well, and if they stopped to think of what that independent body consisted, they would appreciate its magnitude. With their splendid success as a State organization, unparalleled as it was among such organizations, notwithstanding the existence of another State organization in the same field, the fact remained that out of a total of about 10,000 regular practitioners, there were only some 2,000 within the fold of organization, while in the United States, out of a regularly qualified profession of nearly 100,000, only 10,000 were enrolled in the ranks of the American Medical Association. There was therefore a large work before them if they were to aim at the real consolidation of the profession. Still, as he said, the spirit was abroad in the land. It would brook no opposition, and it must work in the direction of union and harmony. The sentiment was deeply graven on the minds of the general profession that to make its influence effective at the State capitals and in Washington the profession must stand together, man to man and shoulder to shoulder. It ought to take but little effort to accomplish a change which was already accomplished in the sentiment of those most concerned. There was not much occasion for the rescinding of resolutions or for the modification of by-laws or constitutions. Some memories of past differences might well be effaced, and some resolutions which had served their purpose might with advantage be modified or revoked. These were subsidiary matters, and could be left to take care of themselves. What was important to remember was that he who interposed authority, prerogative, or prejudice to delay the movement for unity and harmony would be regarded as the enemy of progress. He looked with confidence to that great and efficient organization to help on the good work, and he assured them that from the remotest districts of the country they would find coming back to them words of true encouragement and cooperation. He believed—and he had reason for the faith that was in him—that the medical profession the country over was ready to take any necessary and advisable step in this direction with the end that it might present a united front to the dawning century. (Applause).

Diphtheria and Milk-Supplies.—In a paper on this subject DR. CHAUNCEY P. BIGGS, of Tompkins County, said strong circumstantial evidence had frequently been brought against milk-supplies as being the source of infection in epidemics of diphtheria. There was, however, usually one missing link in the chain, but it had been supplied in an outbreak which had taken place at Ithaca in the beginning of the year. The milk supply of all the families affected was traced directly or indirectly to one dealer. On his farm being inspected no insanitary conditions were found, nor was there any trace of the disease in the household. It was elicited, however, that he bought some of his milk from another farmer, and on the latter's homestead being visited, it was found that several of the family, including those who attended to the cows, were suffering from sore throats, some of the cultures from which were examined, and found to be

diphtheric. The wholesale milkman was prohibited from selling milk for a time, and no other cases developed except such as could be traced to primary infection.

PROFESSOR VERANUS A. MOORE, of Cornell University, read a paper on the **Management of diphtheria** in small cities from a bacteriologic point of view. In the Ithaca case the previous freedom of the city from the disease made laymen and physicians alike skeptical as to the new methods adopted. Several members of the profession had no faith in antitoxin, the fact being that they had never had occasion to test it. The board of health, nevertheless, took drastic measures, making early cultures from suspicious cases, establishing a rigid quarantine and not removing it until a negative diagnosis was made, and then carrying out a thorough system of disinfection. The result was that the epidemic was promptly stamped out.

The tonsils as portals of infection was the subject of a paper by DR. JOSEPH ULLMAN, of Erie County. He especially referred to septic disease as malignant endocarditis, and said he regarded rheumatism as a mild form of pyemia, in which the staphylococci and other organisms became much attenuated. He also spoke of the relation to chorea and tuberculosis borne by affections of the tonsils.

DR. MARCEL HARTWIG, of Buffalo, presented a communication on the **Present status of Jonnesco's operation**, in which he contended that neurectomy of the cervical sympathetic ought to be called by Jonnesco's name.

DR. CLARENCE G. CAMPBELL, of New York, read a paper on the treatment of **Pulmonary tuberculosis** with special reference to the climate of Arizona.

The afternoon session was devoted to a **Symposium on tuberculosis**. It was opened by PROFESSOR VICTOR C. VAUGHAN, of the University of Michigan, who dealt with the general etiology, pathology, and prophylaxis of the disease. Starting with the assumption that the bacillus of Koch was the sole exciting cause of tuberculosis, he proceeded to show that much as has been done in recent years much more still remained to be attempted. He discussed the question whether the bacteria of the disease could exist and multiply outside of the animal body, and came to the conclusion that they could not, except when removed for experimental purposes, and then they only lived for a limited period. There was a pseudo-tuberculous bacillus, but there was no evidence to support the theory that it could change into the bacillus which caused disease in the human body. He contended that no dairyman should sell milk without a license, and that all milk cows should be tested with tuberculin. Tuberculosis, so long as it did not become a mixed infection, was not likely to become malignant. It always began as a local disease, but it had a predilection for the lungs, where it was more likely to become mixed than elsewhere. He advocated the establishment of hospitals and other measures, and said that if this were done there was no reason why the present generation should not eradicate tuberculosis as their ancestors had succeeded in eradicating leprosy. If it was correct as some supposed that the germs differed greatly in virulence, it was important that those already affected should be protected from those who had more malignant germs. He also showed the importance of improving the condition of the poor, among whom the rate of mortality from tuberculosis was far above that among the better off classes. DR. JONATHAN WRIGHT, of Brooklyn, presented the next paper, which was on the **Pathology, diagnosis, special prophylaxis and treatment of tuberculosis of the nose and throat**. It was important, he said, to distinguish between syphilis of the larynx and laryngeal tuberculosis, and he disclaimed the ability to do this without making a thorough examination. In making a diagnosis they should always think of syphilis, and keep on thinking of it. The ideal method of dealing with laryngeal tuberculosis was local and constitutional treatment under climatic change. It was doubtful if a radical cure was ever affected; but much could be done in the way of palliating the dreadful symptoms and prolonging life. He favored intratracheal injections. **Tuberculosis of the eye**, its differential diagnosis, pathology and treatment, was discussed by DR. CHARLES STEADMAN BULL, of New York, and he was followed by DR. SEYMOUR OPPENHEIMER, of New York, whose branch of the subject was **Tuberculosis of the ear**. The latter laid stress on the fact that change of climate, diet and general constitutional treatment were as essential in tuberculosis

of the ear as in ordinary tuberculosis. Surgical measures were contraindicated except in rare cases. PROFESSOR MAURICE H. RICHARDSON, of Harvard, in a paper on **Tuberculosis of the lymphatic glands of the peritoneum**, said the propriety of having recourse to surgery in many cases of this kind seemed unquestionable. The surgical treatment of **Urinary and urogenital tuberculosis** was the specialty treated of in the paper of DR. SAMUEL ALEXANDER, of New York. This form of the disease, he observed, did not differ materially from other tuberculosis, except in the respect that it was more often complicated by pus-infections. There were both primary and secondary infections, and it was strange how little positive knowledge we have in regard to the former. He urged the importance of cooperation between clinical observers and pathologic experimenters with the view of discovering more about the etiology of the disease. The usual remedy was to remove the whole focus of the infection. He believed that generally the epididymis was the original seat of the disease. **Tuberculosis of the bones and joints** was discussed by DR. E. H. NICHOLS, of Boston, and tuberculosis of the skin and superficial fascia, by DR. JOHN A. FORDYCE, of New York. PROFESSOR JOHN G. CLARK, of the University of Pennsylvania, was to have completed the symposium by reading a paper on **Tuberculosis of the female pelvic organs**, but he was unable to be present.

FOURTH DAY'S PROCEEDINGS.

DR. HIRAM N. VINEBERG, of New York, read a paper on the **Differential diagnosis of ectopic gestation**, with special reference to early abortion. He commented on the frequency with which extrauterine gestation was mistaken for ordinary abortion, and maintained that every case of apparent abortion should be looked upon with suspicion, and the patient should be anesthetized, so that a thorough examination could be made, with a view to possible surgical interference. In the course of a short discussion which followed, the president said an examination should never be made without the surgeon being prepared for an abdominal section.

The resources of modern minor gynecology were discussed by DR. A. H. GOLETT, of New York. He protested against the growing tendency to regard gynecology as a purely surgical subject. The resources of minor gynecology were much greater than they were 15 years ago, and yet even before them many cures were effected without surgical intervention. Among the modern resources which were of great value in this species of work, he mentioned the vaginal speculum, the uteroscope, and the cystoscope, sponge tents, etc., besides various anesthetics, electricity, and numerous therapeutic agencies.

DR. JULIUS H. WOODWARD, of New York, read a paper on **Strabismus and its management**. He described the pathology and symptoms of paralytic and nonparalytic strabismus, gave a recapitulation of the differential diagnosis, and pointed out the psychologic and sociologic significance and their relation to eye-strain.

Investigations upon **Specific corporeal gravity**, and upon the **Value of this factor in physical diagnosis** were reported upon by DR. HEINRICH STERN, of New York.

DR. DOUGLAS AYRES, of Montgomery County, read a paper on **Aseptic minor surgery**. He gave a retrospect of the preaseptic period, reviewed the instruments of olden times, and traced the thoughts and provings which gradually led up to the present greatly improved technic. The importance of cleanliness in every detail in preparing for all operations was strongly dwelt upon, and a sketch given of an ideal office.

Amputation at the Hip-joint.—DR. JOHN A. WYETH read a paper descriptive of this operation, and giving a report of 247 cases, in which the author's method of hemostasis was employed. He said, it had always been considered one of the greatest and most difficult of surgical operations, and it was only within a recent period that it had been recognized as justifiable. He then proceeded to show the simplicity and safety with which it could be performed under his methods, and adduced statistics to show that it had reduced the death-rate from such operations to a very large extent, the percentage of those who died in the 247 cases reported being 21, of whom the larger number died from other causes, while under older operations the percentage was 40 and 50, and even higher. Several speakers bore testi-

mony to the success which had attended operations in which the method referred to had been adopted.

DR. JOHN F. ERDMANN, of New York, submitted a report on 3 cases of **Intestinal obstruction due to Meckel's diverticula**. He called attention to the similarity in the symptoms of all three cases to the symptoms of appendicitis, and also to the difficulty of making an early diagnosis between these two conditions.

Intraspinal cocainization for the production of surgical anesthesia was discussed in a paper by DR. S. ORMAND GOLDAN, of New York, which will appear in our next issue. In the course of the discussion which followed, DR. J. RIDDLE GOFFE said he had had the good fortune, while in Paris recently, to accompany Tuffier to the hospital and see him operate. Tuffier was very enthusiastic about the method, which he had been using for about 2 years. He had followed it in about 200 cases, and was perfectly satisfied as to its safety. Several of the other speakers dwelt on the danger of infection and of the cocain reaching the brain, etc., the consensus of opinion evidently being that it was necessary to await further investigations before adopting the method.

Papers on the **Technic of bloodless work**, by DR. ROBERT H. M. DAWBARN, of New York, and **Operative treatment of symblepharon by the use of the Thiersch grafts**, by DR. WILBUR B. MARPLE, of New York, were afterwards read, and the program brought to an end by the reading by title of a paper by DR. EDWARD H. SQUIBB, Jr., of Brooklyn, containing brief comments on the materia medica, pharmacy, and therapeutics of the past year.

New Office-Bearers.—President, Dr. John A. Wyeth, of New York; vice-president, Dr. Alvin A. Hubbell, of Erie County; secretary, Dr. F. H. Wiggin, of New York; treasurer, Dr. Edward H. Squibb, of Brooklyn.

Floating Spleen.—Stephen Smith Burt (*New York Post-graduate*, September, 1900) reports the case of Mary S., aged 27, who appeared at his clinic complaining of discomfort following the lifting of a heavy washtub; there was a circumscribed area of flatness over the center of the abdomen into the right lower quadrant, which proved to be a movable tumor, free from tenderness. On turning this tumor edgewise the smooth, rounded surface, the sharp edge, and the hilum of the spleen were discovered; the organ seemed to be somewhat enlarged. In the proper location for the viscus, there was tympanitic resonance. On restoring the organ to its place the resonance disappeared, but the spleen slowly wandered out of position again. The patient was ordered an abdominal support, but when she returned it was found that the spleen was held firmly in the middle of the abdomen instead of in position; but as this afforded all the relief the patient required, further intervention was not considered advisable. [G.C.H.]

Acute Intestinal Obstruction.—Parker (*Cleveland Journal of Medicine*, September, 1900) concludes that palliative treatment in this condition can rarely be justified. Intussusception and volvulus in children, and impactions low down in the intestine, do occasionally happily right themselves, and abdominal massage and taxis may in these conditions be of some aid; in all others they are dangerous. A most important step in the operation is the careful inspections of the parts while they are in position, before they have been disturbed by any handling. In this manner a collapsed portion of the bowel, or one overdistended and discolored, may point to the seat of the lesion at once. When found, the lesion should be treated radically if the condition of the patient permits, otherwise it should be rendered harmless, as for example an artificial anus should be established which can afterwards be closed; bands must be loosened; strangulations and intussusceptions reduced and twists unrolled. Puncture or aspiration of the distended coils of intestine to facilitate their manipulation and return to the abdominal cavity, Parker has found very unsatisfactory, as only a small portion of the distended gut is relieved, and as many punctures are necessary in order to produce any decided relief. The prognosis in all forms of acute obstruction is unfavorable unless immediate surgical relief is secured. The gravity of the case increases with every half-day of delay. Obstructions due to impactions, bands and intestinal hernias result more favorably than those due to intussusception, volvulus, etc. When gangrene of the bowels has taken place, and general infection is present, the death-rate is high. [G.C.H.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Calendar of Meetings of Philadelphia Medical Societies for the week ended November 3, 1906:
Thursday, November 1.—Obstetrical Society.

The Medico-Legal Society of Philadelphia will meet on Tuesday, October 30. Dr. John B. Roberts will read a paper on *Physicians' Fees*.

St. Vincent's Home and Maternity Hospital of Philadelphia reports having the care, during the past year, of 963 children under 7 years of age, 401 of which still remain in the institution.

Poisoned by Toadstools.—As a result of eating some poisonous variety of mushrooms, 14 persons were recently made seriously ill at Reading, Pa. Of this number 5 are not expected to live.

Ambidexterity in Schools.—It is reported that the Board of Education in Philadelphia is about to undertake to train school children to be ambidextrous through a regular course of exercises to be carried out in the schools.

Smallpox.—Last week 3 new cases of smallpox were reported in Philadelphia. All are white, which is unusual, every case since spring having been colored. The patients have been removed to the Municipal Hospital. The disease is mild but well developed.

St. Luke's Hospital at Bethlehem has recently received a gift of \$10,000 from former president E. P. Wilbur, of the Lehigh Valley Railroad, for the support of a children's ward, and a new \$20,000 operating ward will be erected by Samuel Thomas, of Hokendauqua. Plans for the ward are already in the hands of the contractors.

Typhoid fever is prevalent in Westmoreland Co., there being 200 cases in the town of Boliver, and many in the surrounding country. The epidemic is attributed to impure well water. The 7 cases of typhoid at Ambler, Pa., are said to have been caused by using water from a condemned well, and not from the public supply which is unusually pure.

Vital Statistics of Philadelphia for the week ended October 13, 1906:

Total mortality	336
Disease.	Cases. Deaths.
Inflammation of appendix 3, brain 5, bronchi 6, kidneys 8, heart 2, nerves 1, lungs 22, pericardium 1, spine 1, peritoneum 9, pleura 2, stomach and bowels 12	72
Lungs—tuberculosis of 51, congestion of 1, hemorrhage of 1	56
Marasmus 33, debility 4, inanition 19	56
Heart—disease of 19, fatty degeneration of 1	20
Bright's disease 7, uremia 9, diabetes 1	17
Carcinoma of bladder 1, clavicla 1, liver 3, penis 1, stomach 6, sarcoma of omentum 1, tumor of abdomen 1, brain 2	16
Paralysis 4, apoplexy 11	15
Casualties	14
Diphtheria	13
Old age	10
Cirrhosis of liver	7
Puerperal convulsions	7
Typhoid fever	6
Cholera infantum	6
Suicide—drowning 1, illuminating gas 1, hanging 2, shooting 1	5
Softening of brain	3
Obstruction of bowels	3
Cranosis	3
Whooping-cough	3
Dropsy—brain 1, chest 1	2
Scarlet fever	1
Alcoholism 2, asthma 2, anemia 1, atheroma 1, burns and scalds 2, carbuncle 1, membranous croup 2, drowned 2, gallstone 1, senile gangrene 1, leukemia 1, locomotor ataxia 1, pyemia 1, rheumatism 2, septicemia 2, suffocation 1, syphilis 1, teething 1, ulceration of stomach 1, dysentery 1, unknown coroner's cases 2	30

Charities Receive Legacies.—An adjudication was filed in the Orphans' Court of Philadelphia recently of the account of the Trust Company of North America, trustee for William S. Stewart, under the will of Sarah T. Stewart, deceased. Distribution was made of \$14,871.94, one-fifth to each of the following: Philadelphia Home for Incurables, the House of the Merciful Saviour for Crippled Children, House of Refuge, Presbyterian Orphanage, and Pennsylvania Industrial Home for Blind Women.

Druggists Fined.—War against druggists of the State who have not been complying with the statutes is waged by the State Pharmaceutical Examining Board. It is reported that about 200 informations have been made in Pittsburg; the defendants in the cases disposed of pleading guilty and paying a fine and costs. They will be followed by prosecutions on more serious charges, where the penalties will be imposed by the criminal courts. Out of about 4,000 druggists examined by agents of the State Board, only a small percentage have been found blameless.

University of Pennsylvania.—A bust of Dr. George B. Wood, who was a professor and trustee of the University, will soon be placed in the library. Dr. Wood, uncle of the present Dr. H. C. Wood, died in 1879. He gave his services freely to the University, being a professor in the medical department, trustee and president of the Board of Managers of the University Hospital. The auxiliary faculty of medicine and the Peter Hahn ward of the hospital were founded by him. The pedestal is of granite and has inscriptions on the front telling of his connection with the University and the services he has rendered it.

NEW YORK.

Manhattan State Hospital, Central Islip, L. I.—Dr. William B. Savage, of East Islip, N. Y., has been appointed consulting surgeon.

Coroner's Jury Abolished.—New York State has passed bills, abolishing coroner's juries and putting coroners on salaries instead of fees, except in first-class cities.

Yellow Fever.—Another case was brought to New York from Havana on the *City of Mexico*, October 16, and was sent to the hospital at Swinbourne. The disease was of a mild type.

Galveston Orphans.—A bazaar for the benefit of the homeless Galveston orphans was held recently at the Waldorf-Astoria, New York. It is estimated that the profits will amount to \$30,000.

Appointments.—Albert M. Roehrig has been appointed temporary hospital steward and assistant chemist for duty at Immigration Depot, New York, and W. F. Schlaar has been reappointed senior hospital steward.

Walter B. Duryea has returned to Brooklyn with his broken neck still in a plaster-of-paris frame. He has been under treatment at the sanatorium in Danesville, N. Y., since June. He completed the journey in fine condition.

Suit for Damages.—As the result of using a patent remedy advertised to take off the hair without the use of a razor, a citizen of New York is reported to have lost not only his beard but a large amount of the skin of his face. He is suing for \$2,000 damages.

Typhoid in Training School.—Typhoid fever has broken out in the Boys' Disciplinary Training School of Brooklyn. It is said that the building is in bad condition, and is extremely dangerous to health. The Board of Estimate has been asked to appropriate \$150,000 for a new building.

Plague Serum from Paris.—Dr. A. H. Doty, health officer of the Port of New York, when the plague appeared in Glasgow, ordered a quantity of plague serum from the Pasteur Institute at Paris to be used at Quarantine in the event of the plague being brought to this country. The serum arrived a few days ago and is now in the Quarantine laboratory.

New Bath-houses.—A new, free, public, winter bath-house was opened in New York recently in the crowded East Side quarter. It has marble floors and porcelain tubs, and will accommodate 100 persons at a time. Other free bath-houses will be built in the tenement-wards during the coming year.

Röntgen Society of the United States.—The first regular meeting of this society will be held in the Academy of Medicine, New York City, December 13 and 14, 1900. Membership is open to physicians and to others interested in the general subject. The president of the society is Dr. Heber Roberts, of St. Louis, Mo.

Hospital for the Tuberculous.—The trustees of the Hospital for Tuberculous Individuals have selected 100 acres of land at Big Clear Lake as the site for the hospital, but their action must be confirmed by the Forest Preserve Board and the State Board of Health. Some members of the Legislature favor the placing of the hospital near Clinton State Prison, at Dannemora, where a site is offered free of cost, and where advantage could be taken of the labor of the State Prison convicts. The Big Clear Lake property would cost about \$20,000.

The Craig Colony's Seventh Year.—The Board of Managers of the Craig Colony for Epileptics at Sonyea, Livingston County, N. Y., held their seventh annual meeting at the Colony, October 9. The Board organized for the following year by reelecting Dr. Frederick Peterson, of New York, president, and Mr. H. E. Brown, of Mt. Morris, secretary. This is the seventh time Dr. Peterson has been honored by his colleagues of the Board by being elected president. The report of the medical superintendent, Dr. William P. Spratling, showed that there were 612 patients in the Colony, October 1, 1900. A gain of 234 was made during the past year, the largest number received in any one year since the Colony was opened. The total capacity of the Colony at this time, including the new buildings nearly ready for occupancy, is 840, and it is expected that the Colony will have that number by July 1, 1901. The managers decided to ask the coming legislature for \$169,000 for new buildings and other improvements, and for \$125,000 for maintenance. Of the money asked for special purposes, \$98,000 will be used for dormitories for patients. The superintendent called attention to the fact that 36 out of 612 patients at the Colony are suffering from tuberculosis in some stage, and he strongly recommends that suitable wooden barracks be constructed as soon as possible, in order that these patients may be isolated. It is possible to do this at the Colony on account of the vast size of the Colony estate. The report of the superintendent also calls attention to the great necessity for providing better means of transportation on the Colony. As transportation is now carried on by the use of horses and wagons, it is quite expensive, the estate being so large and the buildings so separated. Dr. Spratling advocates the construction of a trolley system, the power for which already exists at the Colony. The *per capita* cost for "maintenance" during the past 3 years was as follows: 1898, \$100; 1899, \$216; 1900, \$172. It is noted that, as the number of patients increases, the *per capita* cost proportionately decreases. It is believed by the management of the Colony that when its capacity reaches 1,200 to 1,400, the annual cost for maintenance will not exceed \$10.0 a year. A resident pathologist, at \$2,500 a year, with maintenance, will soon be appointed. A laboratory has been built and equipped.

NEW ENGLAND.

The Philadelphia Dental Alumni Association of New England was formed at the recent meeting of the Northeastern Dental Association at Providence, R. I. All graduates of the Philadelphia Dental College are eligible. Dr. James McManus, of Hartford, was elected president, and Dr. Johnstone, of New Haven, secretary.

Smallpox in New Bedford.—Another case of smallpox has been reported in New Bedford, Mass. The child is 13 years old, and is said to have been sick 3 weeks. The epidemic was supposed to be well under control. Recently, 21 patients were discharged as cured from the Clark's Point Hospital, leaving but 23 patients in the hospital.

The Union Hospital Corporation, of Fall River, Mass., will build a large union hospital on a site deeded to the corporation by the Hon. John S. Brayton. The new hospital will cost over \$100,000.

Medical Course at Bowdoin.—On the recommendation of the faculty of Bowdoin College the Board of Overseers, at its latest annual meeting, voted that the work in the first year of the Medical School in physiology and anatomy should be allowed to count as 4 courses each toward the degree of A.B. in the college. Conversely, work in the college in chemistry and biology will, without doubt, soon be allowed to count as courses in the Medical School. Although this movement is in line with the 3 years' degree agitation in the universities, it is noteworthy in the policy of Bowdoin. When, a year ago, the course in the Medical School of Maine was lengthened to 4 years, it was soon found that a combination of the academical and medical courses must be so arranged as to offer completion in 7 years.—[*Medical News*]

CHICAGO AND WESTERN STATES.

The Western Surgical and Gynecological Association will meet in Minneapolis, Minn., December 27-28, 1900.

The Portland (Ore.) Crematory Association has secured a site and will at once erect a crematory at an expense of \$35,000.

The Chicago Eye, Ear, Nose, and Throat College.—The capital stock of this institution has been increased from \$10,000 to \$25,000.

Hospital for Students.—A hospital has been established at Berkeley, Cal., for the purpose of taking care of students at the University of California who may be sick or injured.

Woman Physician for Napa Asylum.—The Board of State Hospital Managers at Napa, Cal., confirmed the appointment of Dr. Myrtle A. Alpin, of San Francisco, as fourth assistant physician at the Napa institution.

Dr. George W. Webster, of Chicago, has been appointed a member of the State Board of Health of Illinois, to succeed Dr. R. F. Bennett, who has succeeded Dr. Stoker as superintendent of the Southern Hospital for the Insane at Anna.

The Southwest Missouri Medical Society met in Springfield, October 13, for a 2 days' session. The president of the organization is Dr. F. B. Fuson; vice-president, Dr. H. J. Rowe; recording secretary, D. C. B. Fulton; corresponding secretary; Dr. J. W. Live; treasurer, Dr. H. C. Shuttee.

Dr. Samuel O. L. Potter has resigned from the board of trustees, and from the chair of theory and practice of medicine and clinical medicine in the College of Physicians and Surgeons of San Francisco, and has severed his connection with that institution, of which he was one of the incorporators.

St. Joseph's Hospital.—The Senn room in this institution in Chicago, endowed for \$10,000 by Dr. Nicholas Senn, has been formally opened. The room is completely furnished by its donor, and the endowment fund will remain intact for its perpetual maintenance. The furnishings include a library of 500 volumes.

No Need of Physicians.—It is reported that the public school principals of Chicago almost uniformly agree that the 50 medical inspectors of schools are of little or no value to the schools, and it is thought the money expended for their salaries, \$2,500 per month for 2 or 3 visits per week, had better be expended for Kindergartens.

The Chicago Gynecological Society held its twenty-second annual meeting, October 19. The new officers elected are: Dr. Reuben Peterson, president; Dr. L. E. Frankenthal, first vice-president; Dr. Henry Banga, second vice-president; Dr. W. H. Rumpf, secretary; Dr. A. H. Foster, treasurer; Dr. C. S. Bacon, editor; and Dr. Emil Ries, pathologist.

Indiana State Board and Medical Colleges.—A new State law in effect this fall provides that first-year students who do not possess a literary degree, a diploma from a high-school, or a teacher's life certificate, must pass an entrance examination before a representative of the board of medical registration, who must not be in any way connected with any medical college.

A Dangerous Wound.—James A. Howell, an Arizona ranchman, is at the Pasteur Institute in Chicago undergoing treatment to prevent hydrophobia from a skunk bite, received recently while camping. So far as is known, no one has ever recovered from the bite of the peculiar species of *Mephitis Americana* common in Arizona, and the case is therefore one of unusual interest.

Dealers in Horse Meat.—It is reported that Health Commissioner Reynolds of Chicago is considering the advisability of licensing dealers in horse meat. Inspectors have discovered that a large amount of the product is being disposed of in the city markets. The facts have been laid before Dr. Reynolds, who has been asked to set aside the prejudice against horse flesh by allowing its sale under proper regulations.

The Mississippi Valley Medical Association will hold its next meeting at Put-in-Bay, Ohio, September 10, 11, 12, 1901. The following is a list of the officers: President, A. H. Cordier, Kansas City, Mo.; vice-presidents, C. F. McGahan, Aiken, S. C., Charles L. Minor, Asheville; secretary, Henry E. Tuley, Louisville, Ky.; treasurer, Dudley S. Reynolds, Louisville, Ky.; chairman of committee of arrangements, J. C. Culbertson, Cincinnati, Ohio.

Emergency Ration Test.—Captain Fountain and Captain Foster, of the Emergency Ration Board of the War Department, who have been in Kansas City for several weeks preparing the rations for an actual test, will leave for Fort Reno, I. T., soon with a troop of cavalry. The ration is put up in an elliptical can 8 inches long. Each day's food weighs a pound, and each can contains 3 cakes of sweet chocolate and 3 cakes of a food preparation composed of meat and grain compound. The effect of the food on the men will be carefully noted. They will be weighed every day and their condition carefully observed by a physician. The test will probably last 2 or 3 weeks.

An experimental air-washer in the Chicago Public Library promised so well that the authorities have decided to install a plant capable of purifying sufficient air for the entire building. It is a simple process. The air is drawn into a box through a system of water sprays and over a series of metal plates. The sprays take out all the shavings, bits of straw and paper, filaments of cotton and wool, etc., which float out of a drain at the bottom of the box. The damp air is then forced over another series of plates by a great fan. These plates are set at slight angles to each other and have flanges which, as the air passes around them, catch the dirt. It is said that if a person's hand is inserted in this compartment it will quickly become black with dirt. In summer the air which emerges from the ventilators is cool, but dry, while in winter it will be warmed by first passing over steam pipes. Injury to the books and to the mural decorations prompted the plan for the cleansing of the air, but patrons of the library will profit quite as much as the books and the paintings. Not only does the apparatus remove the dirt, but the odors as well, and, presumably, many germs.

SOUTHERN STATES.

A nurses' training school for colored girls is to be established at Jacksonville, Fla., by the Methodist Woman's Home Missionary society.

The Southern Surgical and Gynecological Association will hold its thirteenth annual meeting in Atlanta, Ga., November 13, 14, 15, 1900.

The Episcopal Eye, Ear, and Throat Hospital of Washington, D. C., reports that since the opening of the hospital, 3½ years ago, 23,325 visits have been made to it by 5,007 patients, and 799 operations have been performed.

Twins and Triplets.—It is reported from Huntingdon, W. Va., that twin sisters who had married twin brothers, recently gave birth to triplets within an hour of each other.

New Orleans boasts of being the healthiest town in the country with the lowest mortality among the large cities. The death-rate in August was 14.05 per 1,000, the lowest recorded in any large city, and the lowest ever known in New Orleans for a month.

From Washington to Manila.—Hospital Steward Alfred Bauer and 50 privates of the hospital corps at the Washington Barracks, D. C., have been ordered to duty in the Philippines. They will embark on the transport *Buford*, which will leave New York for Manila early in November.

Fatal Horse Disease.—Cerebrospinal meningitis has broken out for the second time within the past year among horses in Southern Maryland. It is estimated that about 1,000 have died. Appeals for assistance have been received at the Maryland Agricultural College and Dr. Samuel Buckley has been sent to investigate the matter. He has been making extensive experiments with a serum, with which by inoculation he hopes to prevent the spreading of the disease.

The Freedmen's Hospital, D. C.—The annual report of this hospital by the Surgeon-in-chief, Dr. Curtis, shows quite a large increase in the number of patients with a percentage of about 85% of those cured or improved, and a mortality of 6.37%. The relatively large number of cases of cancer in the gynecologic department is noticeable, since the prevailing opinion has been that the descendants of the African race were rarely affected with this disease. The training school for nurses connected with the hospital has been admitted to the American Association of Nurses. Dr. Curtis holds that the institution should remain intact and under the supervision of the Interior Department, as Freedmen's Hospital is a national hospital for the use and benefit of the indigent sick from all sections of the country. The percentage of nonresident patients treated in this institution is far in excess of the resident class. The report urges a number of new buildings and other improvements.

Richmond, Va.—The testing of the eyes of the pupils in the public schools has, in spite of frequent and decided opposition, made some headway in this city. Dr. ALFRED C. PALMER, after a great deal of work on the school board, inaugurated, last session, a systematic examination of the children's eyes, but strange to say his work was confined to the pupils of the High School, beginning, of course, at the wrong end; but a start had to be made somewhere. He found about 30% of the pupils had more or less defective vision. This session the examinations will be conducted in all of the 19 schools. Dr. Palmer meets the teachers of each school, furnishes them with test-cards and thoroughly instructs them in their use. They make the preliminary tests, the cards are then returned to the oculist, and all the children whose vision falls below 33 are carefully examined by Dr. Palmer, who then sends a notice to the parents advising them to consult some reputable oculist. Poor children are treated at the eye clinics in the dispensaries free.

Medical Society, District of Columbia.—Dr. W. W. JOHNSTON read the history and showed the specimen of a very large thoracic aneurysm. The patient was a male, 35 years of age, who reported an old specific history. The aneurysm first showed itself in the Philippine Islands 18 months ago. The tumor grew rapidly in the right infraclavicular region until it extended from the right shoulder and axilla to the sternum. He was brought to Washington in June, 1900, after having been treated by glycerin injections for some weeks in Hongkong. Twelve inches of silver wire were introduced into the aneurysm and a current run through the wire from an electric battery for an hour, the latter part of June. The patient died from hemorrhage the last of September. On autopsy the aneurysm measured 9 inches transversely and 7 inches in the antero-posterior diameter and came off from the ascending aorta very near the heart. The entire aneurysmal sac was filled with a large laminated clot in which the silver wire was imbedded. The greater portion of the wire was coiled at the base of the aneurysm directly in the blood current. From

postmortem appearance it is difficult to understand how blood escaped to cause the patient's death, unless it found its way around the surface of the clot, between the clot and the sac, which, however, appeared to be in close contact.

MISCELLANY.

Soldiers From Manila.—On October 16 the transport *Logan* left Manila for San Francisco with 273 sick, and 10 insane soldiers on board.

In Hawaii the only direct effects of the plague were that the quarantine restrictions prevented, for a time, the use of Honolulu as a port for the transport service. None connected with the military service contracted the disease.

A Sanatorium at Manila.—A correspondent at Manila says Luzon is to have a sanatorium shortly, which will place the city of Manila on the same footing as other capital cities in the Orient, and have manifold advantages. Plans are now under consideration for the establishment of this very important requisite for dwellers in the tropics, and the locality has been selected.

Physician as Diplomat.—Dr. Eduardo Wildo, the new minister from Argentina to this country, at the time of his appointment held the post of president of the National Department of Hygiene. He planned most of the colleges and hospitals throughout Argentina, and is an author of distinction in medical science. His first diplomatic work was the negotiation of the sanitary convention between Argentina and Uruguay in 1872.

Yellow Fever is still raging in Cuba. General Lee says that heretofore it has been confined to small, narrow streets, and places lacking in sanitation, but now it appears in places where it was never known before. The winter there does not get cold enough to eradicate the disease before January. General Lee says: "The sanitation is first class in all places where the disease is raging, and has been for months. The doctors are beginning to say that there is nothing in sanitation after all. The sanitation laws have been carried out strictly since the military authorities of this country assumed charge in the island."

The American Red Cross Society has begun its work in behalf of the sufferers from the famine in India. The work for the present is in the direction of accumulating funds. As soon as a sufficient amount of money has been received, the Red Cross agents will be sent to India. The plan of relief will be the same as that so successfully operated in Cuba. Men and women will not be gratuitously supplied with food and clothing. Work will be demanded of them, and the society will make an effort to have the farms again worked and return persons to their chosen paths of trade and industry.

Improvements at Quarantine.—The State Quarantine Board has decided to increase the efficiency of the station at Marcus Hook by erecting a detention barracks there to accommodate 400 patients. The board also has decided to provide a tug for boarding vessels, and to construct a large disinfecting plant. An important resolution has been adopted to facilitate the operation of the new line of steamers to Savannah. It provides that the quarantine regulations on coasting vessels from points north of St. Mary's River, Fla., shall be lifted from November 1 to March 31.

Health of Troops in Puerto Rico.—The report of John Van R. Hoff, chief surgeon of the Puerto Rico Division of the Army, contains an important passage which deals with the prevalence of syphilis. It says: "Venereal diseases still maintain their unenviable prominence, the annual rate being 506 per 1,000, against 467 last year. It is interesting to observe that these diseases are quite as prevalent among the Puerto Rico Volunteers as among the regular troops, which supports the position taken in my latest annual report that the people here are syphilized." A number of the worst cases were discharged "without honor." This action was not sustained by the War Department. In malarial diseases the Puerto Rico Volunteers show proportionately a much larger number of cases than the regular troops.

Obituary.—FRANKLIN SMITH, of New York City, October 9, aged 76.—WILLIAM B. WILSON, of Cape Girardeau, Mo., October 18, aged 69.—JOHN W. ELSTON, of Kansas City, Mo., at Burela, Col., October 12, aged 56.—WILLIAM R. LARKIN, of New York, October 15, aged 42.—BENJAMIN HUSSEY WEST, of Neponset, Mass., October 11, aged 86.—JOSEPH L. CUTLER, of Bolivar, N. Y., October 12, aged 71.—HENRY MORTON, of New York, October 20, aged 93.—W. T. NEWTON, of Indianapolis, October 21.—JOHN W. ROBINSON, of South Lyons, N. Y., October 21, aged 51.—JACOB ISZARD, of Glasboro, N. J., October 20, aged 55.—EDWIN S. THOMAS, of Philadelphia, October 17, aged 72.—WILLIAM FRANK REILLY, of Carlisle, Pa., October 19, aged 48.—LOUIS LESASSIER YOUNG, U. S. Navy, at Denver, Col., October 6, aged 35.—W. H. STURGEON, of Uniontown, October 16, aged 74.—J. L. CORRELEY, of Newburg, W. Va., October 16.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended October 19, 1900:

SMALLPOX—UNITED STATES.

U. S. Army Report.—Surgeon-General Sternberg in his recent report for the fiscal year ended June 30, 1900, says: "The *Medical Department* consists, at present, of 192 officers, a number which barely sufficed for the needs of the Army before the outbreak of the late war with Spain, and which proved utterly inadequate in number, notwithstanding the earnest efforts of its members to form a satisfactory basis of organization for the large increase made to our military forces during the progress of that war. Similarly since the close of the war it has been impossible for the Medical Department, without professional assistance from civil life, to provide for the sanitary and medical work at the large number of new posts and stations that have been established at home for coast defense, in Cuba, Puerto Rico and Hawaii for garrison duty, and for the military operations in the Philip-

pine Islands. Excellent assistance has been obtained by contract with civil physicians, so far as concerns the professional care of the sick and wounded, but much experience is required to fit these medical men for the sanitary work of their position and to familiarize them with Army methods. *United States Volunteers.* At the end of the year there remained in service 34 surgeons with the rank of major, 11 of whom were captains in the regular establishment. On June 30, 1900, there were 78 *regimental surgeons and assistant surgeons* in the service, 25 majors, 13 of whom were captains in the Regular Army, 27 assistant surgeons with the rank of captain, and 26 assistant surgeons with the rank of first lieutenant. In the service 462 acting assistant surgeons are under contract." All contract surgeons now in service have been examined by boards of medical officers to determine their fitness, physical and professional, for the discharge of their duties. A board of medical officers was appointed to meet at one of the general hospitals in or near Manila, P. I., for the purpose of studying tropical diseases as they occur in those islands. Another board was appointed to meet at Camp Columbia, Quemados, Cuba, for the purpose of pursuing scientific investigations with reference to the infectious diseases prevailing on the Island of Cuba. The number of *hospital corps men* in service June 30, 1900, was 167 hospital stewards, 381 acting hospital stewards, and 3,543 privates; a total of 4,091. The number of female nurses in the *Army Nurse Corps* has remained approximately constant during the year, there having been 187 in the service July 1, 1899, and 210 on June 30, 1900; 165 contracts were made and 149 were annulled. The movement of troops to the Philippines has occasioned a corresponding movement of nurses, and 122 are there now against 33 at the beginning of the year. Female nurses have recently left Honolulu and the hospital-ship "Relief," but are serving in increasing numbers on the Army transports in the Pacific. The organization of the Army Nurse Corps has been steadily improved and its adjustment to the Army made more satisfactory in details. The work of the nurses continues to be highly appreciated and their services are in demand at almost all hospitals of importance. During the past year modern hospitals were completed at Fort Adams, R. I., Madison Barracks, N. Y., Fort Slocum, N. Y., and Fort Banks, Mass. New hospitals are being erected at Fort Terry, N. Y., Fort Preble, Me., Fort Williams, Me., Fort Strong, Mass., Fort Leavenworth, Kans., Fort Ontario, N. Y., Fort Howard, Md., Fort Dupont, Del., and an important addition is being made to the hospital at Washington Barracks, D. C. A general hospital or sanitarium for the treatment of officers and men of the Army suffering from pulmonary tuberculosis has been established at Fort Bayard, New Mexico. Besides the special hospitals at Hct Springs, Ark., and Fort Bayard, N. M., there are now in the service in the United States only 2 general hospitals; one at Washington Barracks, D. C., and the other at the Presidio of San Francisco, Cal. The one supplies the needs of the troops serving in the eastern part of the country and is utilized as a training school for recruits for the hospital corps. The other receives sick men from organizations en route to the division of the Philippines and patients sent from the hospitals in Manila for the benefit of the home climate. During the calendar year 1899 there were 229,885 admissions to the sick report recorded in a mean strength of 105,546 regulars and volunteers. The death-rate from all causes was equal to a loss of 29.93 men per thousand of strength during the year, but only 11.80 of this was caused by disease. In the Army, regulars and volunteers, during the calendar years 1898 and 1899, there were reported on the monthly reports of sick and wounded 347 cases of insanity and 202 of these cases were committed to the Government Hospital for the Insane. Of the commitments 135 recovered in an average period of 3.9 months, 13 were improved, 6 died, and 49 remained unimproved. Of the 347 cases, 96 were reported on the monthly reports of troops serving in the Pacific Islands, and 32 of these were sent to the Government Hospital for the Insane. Of those committed 17 recovered in an average period of 3.6 months, 13 were improved, 2 died, and 11 remained not improved. The Surgeon-General says the exposures, fatigues, and excitements of a prolonged campaign are responsible for the large sick report and the relatively large death-rate among the troops in the Philippines. However, the opinion is prevalent among our medical officers that in time of peace and doing

only garrison duty, the sick-rate of the Army in the Philippine Islands would be no higher than it ordinarily is in the southern United States. The latest reports received from the chief surgeon, division of the Philippines, dated August 15, 1900, show a percentage of 8.47 sick for the command, which on that date had a strength of 60,554. The subsistence allowance of 40 cents a day has proved ample at all posts to give the sick and wounded the special diet which they require.

Changes in the Medical Corps of the U. S. Army for the week ended October 20, 1900:

- LATIMER, CHARLES H., acting assistant surgeon, will report at First Reserve Hospital, Manila, P. I., for duty.
- POWELL, Major JENES L., surgeon, is relieved from duty in the department of Northern Luzon and assigned to duty as commanding officer of the Second Reserve Hospital, Manila, P. I.
- ARMSTRONG, Major SAMUEL T., surgeon, is relieved from duty in the department of the Visayas and will report to the commanding general, department of Southern Luzon, for assignment to duty.
- DAVIS, Major JOHN G., surgeon, is relieved from duty in the department of Southern Luzon and will report to the chief surgeon of the division of the Philippines for instructions.
- GRAVES, ALONZO, acting assistant surgeon, recently appointed, now at San Nicholas, province of Pangasinan, Luzon, will report by letter to the commanding general, department of Northern Luzon, for assignment to duty.
- DE NEIDEMAN, Major WILLIAM F., surgeon, is relieved from duty at First Reserve Hospital, Manila, P. I., and will report to the commanding officer, Thirtieth Infantry, U. S. Volunteers, for duty as surgeon with that regiment.
- BLAKE, JOHN C., hospital steward, is relieved from duty at hospital No. 3, Manila, P. I., and will report on the transport "Stephens," scheduled to leave on August 30, to San Francisco, Cal., for duty on that vessel while en route, reporting to the commanding general, department of California, for instructions to return to the division of the Philippines.
- MANSFIELD, ELMER E., acting assistant surgeon, now on duty with the Twenty-fifth Infantry, is assigned to the Twenty-fourth Infantry, to relieve Acting Assistant Surgeon Wharton B. McLaughlin, on account of sickness in the latter's family.
- McLAUGHLIN, WHARTON B., acting assistant surgeon, on being relieved, will proceed to the Presidio, for temporary duty awaiting transportation to the Philippine Islands.
- HARVEY, L. S., acting assistant surgeon, is granted leave of absence for 1 month, with permission to leave the limits of the division of Cuba, and to apply for an extension of 1 month.
- GODFREY, Captain GUY C. M., assistant surgeon is relieved from further duty in the division of Cuba, and will comply with par. 25, S. O. 185, c. s., H. Q. A., proceeding via New York City.
- BERKART, JOHN L., acting assistant surgeon, is assigned to temporary duty on the transport "Leelanaw" during the voyage of that vessel to the Philippine Islands. Upon arrival at Manila, he will report to the commanding general, division of the Philippines, for assignment to duty.
- SCHLAGETER, H. J., acting assistant surgeon, is granted leave of absence for 1 month, with permission to apply for an extension of one month.
- CARROLL, JAMES, acting assistant surgeon, is granted leave of absence for 20 days, on surgeon's certificate, with permission to go beyond the limits of the division of Cuba.
- MUNSON, Captain EDWARD L., assistant surgeon, is granted extension of leave of absence for 15 days on account of sickness.
- BALCH, Major LEWIS, surgeon, is honorably discharged from the service, to take effect November 7, his services being no longer required.
- PILCHER, Captain JAMES E., assistant surgeon, will report at Fort McHenry for examination by a medical officer at that post as to his physical condition, and upon the completion of the examination will return to the place of receipt by him of this order.
- GODFREY, Captain GUY C. M., assistant surgeon, now in Brooklyn, N. Y., en route to San Francisco, Cal., under par. 25, S. O. 185, August 8, is relieved from further operation of the order specified, and will report about November 7 to the commanding general, department of the East, for assignment to duty with recruits en route to the Philippine Islands on the transport "Kilpatrick." Upon his arrival at Manila and the completion of his duty with the recruits he will report to the commanding general, division of the Philippines, for further orders.
- ANDERSON, JOHN B., hospital steward, Army General Hospital, Presidio, will be discharged from the Army, by way of favor.
- GABLINGTON, JOSEPH C., acting assistant surgeon, now in Washington, D. C., will proceed to Fort Mott, for duty, to relieve Acting Assistant Surgeon Thomas D. Ingram.
- INGRAM, THOMAS D., will proceed to Washington and report to the Surgeon-General of the Army for annulment of contract.

Changes in the Medical Corps of the U. S. Navy for the week ended October 20, 1900:

- DEER, E. C., medical inspector, is detached from the Navy Yard, Portsmouth, N. H., on reporting of relief, and ordered home to wait orders.

STEPHENSON, F. B., surgeon, is ordered to the Navy Yard, Portsmouth, N. H., October 25.
ODELL, H. E., assistant surgeon, order to the Asiatic Station, modified; to take passage on the "Solace."
STEPHENSON, F. B., medical inspector, is commissioned medical inspector from May 31, 1900.
DUNN, H. A., assistant surgeon, is detached from the "Dorothea," and ordered to the "Frolic."

Changes in the U. S. Marine-Hospital Service for the week ended October 18, 1900:

GASSAWAY, J. A., surgeon, is granted leave of absence for four days from October 15, under provisions of paragraph 179, Regulations, M. H. S.
STONER, G. W., surgeon, granted 3 days' extension of leave of absence. October 16.
STONER, J. B., passed assistant surgeon, granted leave of absence for 22 days from October 30. October 12.
YOUNG, G. B., passed assistant surgeon, granted leave of absence for 1 day. October 12.
CURRIE, D. H., assistant surgeon, to proceed to Indianapolis, Ind., in charge of the laboratory exhibit of the service to be shown at the meeting of the American Public Health Association. October 12.
SCOTT, E. B., hospital steward, granted leave of absence for 20 days from October 22. October 13.
ROEHRIG, ALBERT M., appointed temporary hospital steward and assistant chemist for duty at immigration depot, New York, N. Y. October 13.
SCHLAAR, W. F., reappointed senior hospital steward. October 13.
Board convened to meet at the purveying depot, New York, N. Y., on Wednesday, October 24, for the purpose of revising the official supply table of the service.—Detail for the board: Surgeon G. W. STONER, chairman; Surgeon C. E. BANKS.

foreign News and Notes.

GREAT BRITAIN.

Sanatorium.—A new sanatorium has been begun near Frodeham as an accessory to the Liverpool Hospital for Consumptives.

Sanitary Ice Cream.—The premises where ice cream is manufactured in Plymouth are registered and supervised by sanitary authority.

Death Rate.—The death-rate in London during September equaled an annual rate of 16.5 per 1,000. In Dublin the rate was 25 per 1,000.

Medical Students Fined.—The medical students who were arrested in London, for breaking up the meeting of John Alexander Dowie, the divine "healer" of Chicago, were fined.

"The Tale of a Field Hospital."—A work under the above title will soon be issued. It is written by Mr. Frederick Treves and is a record of his experiences in South Africa.

King's College Laboratories.—The new science laboratories of King's College, London, will be opened October 30. The new buildings and equipment have cost over £20,000.

Medical Members of Parliament.—Among those selected are Sir Michael Foster for the London University and Sir J. Batty Tuke for the Universities of Edinburgh and St. Andrews.

Objectionable Pamphlets.—Efforts are being made to stop the sending of certain pamphlets through the mail by druggists. Some are sent from America and contain testimonials from British physicians.

Lunacy in Ireland.—The inmates of the various hospitals, January 1, 1900, was 20,863, as compared with 20,304, January 1, 1899. There was an increase in district asylums, and a decrease in private asylums and workhouses.

Unqualified Practice.—A Mr. Pleavin of Birkenhead was recently before the Coroner charged with causing the death of a child by illegally practising medicine. The gentleman "swore that he was a doctor of medicine of Ohio, Buffalo, United States of America."

Seaweed as a Test for Sewage.—Experiments with the *Ulva latissima* has shown that this plant flourishes only in water that is contaminated by sewage. This was proved after noting the large quantities of hydrogen sulfid given off by the plant when washed up at Dublin and Belfast.

The Sanitary Institute.—Examinations in practical sanitary science for inspectors of nuisances will be held in many cities during 1901. There will also be an examination in hygiene for school teachers in Loudon and Bradford. Practically the same work is carried on in Sydney, Australia.

Sick Soldiers in Steerage.—The fact that the British Admiralty was sending home in the steerage 12 Australian soldiers sick with enteric fever aroused indignation in London and a charity fund has been wired to Gibraltar, where the troopers have been recuperating, to insure their transfer to the second cabin.

Lunacy Scandal.—A patient in the Manchester Workhouse was "quietened" by an attendant by twisting a towel around his neck by means of a poker. The patient died, and post mortem showed fracture of the cartilages of the larynx and of the hyoid bone. The attendant has been held on the charge of murder.

Drunkenness.—The Royal commission presided over by Lord Peel recommend that drunkenness *per se* in public should be considered an offence. It is estimated that if the law now in force in Russia, that of arresting all intoxicated persons found on the streets and in public places, were enforced in London, at least 10% of the population would be in gaol.

Record for Insanitation.—Eight years ago the report to the local Government Board stated that "in almost everything which is needed to make a town healthy Kilkenny (Ireland) is deficient." The town still maintains this distinction. It has had 300 cases of diphtheria during the past year and an epidemic of enteric fever. A private individual has impeached the sanitary authorities for neglect of duty.

Hospital Abuse.—Attention is being called to a new form of this fertile topic. It is that of persons conducting a large business, who make a charitable contribution to a hospital, and then send all their employees there for the treatment of all manner of injuries and sickness. It is asserted that not a single hospital in London will reject the employees of a large subscriber to their funds, even though they be able to pay for medical attendance.

Infectious Diseases in London.—The report for 1899 shows that the number of notified cases was 42,285. Of these, 68% were admitted to the Board's hospitals. The average residence of scarlet fever patients was 70 days, and of diphtheria cases 59 days, while the enteric fever average reached 58 days. A noticeable feature is the steady decrease in mortality among scarlet fever patients, while still greater is that in diphtheria—from 23% in 1895, when antitoxic serum was introduced, to 14% in 1899. London still continues to enjoy immunity from smallpox, 28 patients being sent to the hospital during the year, and of these only 10 really had the disease. The cases of mistaken diagnosis numbered 4% in scarlet fever, 7% in diphtheria, and 17% in enteric fever.

The Glasgow epidemic of plague is under control. One fatal case occurred at Cardiff, October 4. The Public Health Committee of the London County Council have recommended the use of several properties as isolation houses if the plague invades London. Professor Zabolotny, of St. Petersburg, who has been at Glasgow, recommends preventive inoculations of serum. Extraordinary precautions are being taken by the authorities in Glasgow and in London to prevent further outbreaks or invasion. For the bacteriologic examination of suspected cases instructions are to send a sample of blood from a finger after venous congestion has been produced, fluid from a discharging bubo, and expectorated material. The sanitary condition of Dartmouth has been found bad, and there is no isolation hospital or arrangements for disinfecting. Dr. Gairdner insists that suspected cases be reported even if no diagnosis has been made.

Inspection at Glasgow Inadequate.—Dr. William T. Jenkins, Commissioner of the New York Board of Health, is reported to have said when referring to his visit to Glasgow, that in his opinion a few ounces of timely prevention would have saved all the trouble over the bubonic plague there. He asserted that England was in no respect in advance of the American system of municipal hygiene, adding that the system of inspection in Glasgow was wholly inadequate for such an important port.

CONTINENTAL EUROPE.

Medical Students in Italy.—During the past year 6,648 students attended the various universities. Naples led with 2,009.

The new Pasteur Institute at Kasauli, India, is thriving in spite of petitions and indignation meetings of antivivisectionists.

Methodic Treatment of Epilepsy.—Professor Gilles de la Tourette has published his treatment of epilepsy. Bromids only are employed.

Tropical Medicine.—M. Le Dantec is to give a course of lectures on this subject at the University of Bordeaux. Dr. J. H. Kohlbrugge lectures on the same subject at the University of Utrecht.

Leprosy in Germany is said to be increasing. In Prussia, in the district of Memel, close to the Russian border, 21 cases have been discovered so far. At Hahmburg 10 cases have been found, and in Mecklenburg-Schwerin one.

Another Tuberculosis Cure Futile.—An establishment founded in Belgium 3 months ago for the raw meat treatment of tuberculosis has closed its doors. The manager declared the method was of no value, though the medical press wonders how he arrived at this conclusion in so short a space of time.

Microbe light is the latest Paris invention. A French chemist, Raphael Daboïs, is said to have found a way of nourishing phosphorescent germs in glass vessels, which soon emit a light about as bright as the moon. He expects to increase its intensity, and believes that its being entirely free from heat will give it a scientific value.

Professional Secrecy.—The Court of Appeal of Toulouse has allowed a remarkable exception to the law that professional secrecy is absolute. The trial was as to the disposition of some property, and the Court received the evidence of the physician as good, because it contained 2 classes of facts—those which the medical man obtained as a friend, and those concerning the complaint of the deceased, which were common knowledge after his death.

Dr. Yersin and the Plague Serum.—From Marseilles comes the report of an interview with Dr. Yersin, famous as the discoverer of the antiplague serum, who arrived there recently from Tong King. He described the large laboratory which he has organized in that country, where 30 horses serve for the culture of a new and improved serum, which can be used indifferently for persons or animals. He is highly satisfied with the results everywhere obtained where the serum has been administered under normal conditions. The terrible epidemic that raged among the herds of Indo-China has been almost entirely stamped out, thanks to the efforts of this laboratory. Horses employed there do not suffer at all from the treatment, and when other horses come to take their place, can be easily utilized for field work. Dr. Yersin is somewhat surprised at the news of the appearance of the plague at Glasgow, and regards it as an isolated case. He says that the scourge is necessarily losing force.

Patent Medicine Ethics.—At the meeting in Aachen of the Society for the Advancement of the Natural Sciences, H. His, Jr., advanced the following points regarding the endorsement by physicians of newly discovered medicaments. 1. The relations between the manufacturers of and the endorsers for pharmacological and medical products ought to be adjusted and regulated by some central institution. 2. The signing and endorsing of such products should be for the personal information and benefit of the manufacturer, but

never for publication by him. 3. Physicians should never recommend in the public lay prints newly-discovered medical products or food preparations. 4. There should be greater conservatism in the matter of subscribing to the merits of a new drug, and the publishing of such endorsement should be reserved exclusively to the technical publications and medical press. 5. The articles appearing in the medical journals should be protected as far as possible against reprint for purposes of advertisement. 6. To demand or receive pecuniary benefits from signatures, recommendations, endorsements or publications regarding new preparations is inadmissible. 7. Physicians whose inventions are set up for sale are responsible for the manner of advertising them. [Medical News.]

MISCELLANY.

A Hospital is to be founded at Su San in Corea, in memory of Rev. W. N. Junkin of New Jersey.

Convicted of Proenring Abortion.—A physician in Sydney, Australia, has been sentenced to 5 years penal servitude for unlawfully causing abortion.

Sydney Hospital.—The honorary medical staff have protested against the appointment of an honorary anesthetist. Between 1892 and 1899 anesthetics were administered 11,408 times with only one death.

Chirata as a Cure for Drunkenness.—This plant has been used in India for many years as a cure for drunkenness. The cure is only temporary and must be taken from time to time.

Medical Missionaries.—One of the difficulties encountered by medical missionaries in China is that patients, after receiving gratis a bottle of medicine, are apt to sell it to some one else for a trifle.

Cholera Increasing in Japan.—It is reported that cholera is increasing to such an extent in Japan that steamers thence have been quarantined. The dispatch adds that there have been a number of deaths on board of steamers coming from Nagasaki.

Hospital Statistics from South Africa.—Three months' work in the Irish Hospital at Pretoria gave a mortality of 11.6% in enteric fever cases. At the Bloemfontein section hospital the mortality was 12.6. The Volks hospital at Bloemfontein (Boer) shows an enteric mortality of 8.5. This difference is stated to be due to less strict methods in classifying fevers.

Colonial Medical Officers.—The *Lancet* contains a complaint from a physician that the colonial medical officers on the west coast of Africa are not paid as much as they should be, and that their quarters are not fit for Europeans in a tropical climate. Of 6 items mentioned 5 are "considered repellant when applied to such an unhealthy climate." The other item, which is considered just, is 6 months' leave for every 12 months' service.

Physician and Poisoned Arrows.—In the recent fighting in Nigeria, West Africa, out of the British detachment a colonel, 2 captains and 15 privates were wounded with the poisoned arrows used by the natives, the poison of which has been known to prove fatal in a few minutes. Dr. Thompson, the surgeon of the expedition, as soon as the officers were wounded, sucked the blood from the wounds and with it the poison. He then gave the same treatment to the privates and all recovered. The doctor himself experienced no ill effects from his action.

Obituary.—JOHN FREDERICK FRANCE, of London, October 30.—BENJAMIN JONES MASSIAH, of Didbury, September 30, aged 53.—CHARLES BOWMAN WILSON, of Liverpool, October 9, aged 73.—ROBERT STRAFFORD SMITH, of Belfast, October 5.—ODED LOWSLEY, of Reading, October 4, aged 62.—RICHARD HENRY WILSON, of London, October 9, aged 63.—ALICE STEVENSON, of Glasgow, September 3, aged 31.—A. E. LOVITT, of the China Inland Mission.—ARTHUR DE NOE WALKER, of Chelsea, aged 71.—VISHRAM RAMJEE GHOLAY, of Poona.—RUDOLF ARNDT, of Greifswald, aged 66.

1.—Lister in his **Huxley Lecture** goes over, in quite a thorough manner, the various experiments which he has made in relation to **coagulability of the blood**; especially in its relation to pyemia. Lister says that the accumulation of the blood-corpuscles, both red and white, in the vessels of an inflamed area, is due to a tendency on their part to adhere to each other and to the walls of the vessels. This adhesiveness or viscosity is not manifested at all when the vessels are in a perfectly healthy condition. An interesting phenomenon discovered while experimenting on bloodvessels of a frog's foot, was noticed in the changes of the arrangement of the pigment of the epithelial cells, evidently resulting from the irritant. The pigment which in the healthy part was seen in small round dots, changed as the result of the irritant to a delicate black network, causing an extremely dark appearance. In this changing, the form of the cell remained unaltered, but the pigmentary constituents were transferred from place to place. This change Lister claims is due to a prostration for the time being of the vital energies of the tissues acted upon by the irritant. Another interesting experiment was done with the ciliated epithelium from the frog's tongue. It was found that when warmth was applied, the cilia waved very rapidly, but suspended their action if the heat was increased. If the heat was removed in time, the cilia again began to move. This demonstrated the fact that a destructive agency used to a degree, just short of that which is lethal, may increase the vital functions of the tissues acted upon. In severing the sciatic nerve, only temporary dilation of the bloodvessels was noticed. To obtain complete paralysis of the bloodvessel walls, it was necessary to sever the spinal cord, and if a single filament was left intact, the bloodvessels would regain their tone. If with a fine needle the severed medulla was pricked and irritated, tetanic contraction of the bloodvessels was noticed. This seems to argue for the reflex theory of inflammation. That this **reflex inflammation** is possible, was demonstrated by an experiment on the eye of a rabbit. A small bit of thread was inserted just beneath the conjunctiva, and on killing the rabbit 48 hours afterward, marked congestion and inflammation of the posterior portion of the eyeball was found. Regarding the coagulability of blood, Lister found that a quantity of blood could be retained in a fluid state for 48 hours, in an excised jugular vein taken from an ox just

after being knocked down. The blood from this vein was carefully drawn into a glass tube, with both ends sealed. The greater part of the blood in the tube was found to be fluid, after 24 hours and there was a clot about $\frac{1}{3}$ of an inch in thickness crusting the interior of the tube. This result seems to be of itself sufficient evidence that blood requires no action of the living vessels to maintain its fluidity. [G B W.]

2.—In an address delivered at the opening of the session of the London School of Tropical Medicine, MacGregor refers to the way in which new diseases are distributed among new races. Typhoid fever was introduced into Fiji by the British. The Lini Islanders introduced tinea imbricata to Fiji and contracted yaws; while the Solomon Islanders contracted some form of venereal disease. Venereal disease was taken to the Pacific Islanders and to the Papuans by Europeans. Fiji was a center for the distribution of measles in 1874. The epidemic that resulted destroyed between $\frac{1}{3}$ and $\frac{1}{2}$ of the whole population. Europeans introduced dysentery to Fiji, and this disease now causes more deaths than any other in tropical countries. Water examination is very important in the tropics, since it is a factor in the continuation and spread of malaria, as well as of other diseases. [J M S.]

3.—Godlee says that **subphrenic abscess** is not an isolated abscess of its own account, but rather caused by some other phenomena, and most probably the symptoms of the disease which caused it will be the prominent ones. For this reason it is almost impossible to isolate the symptoms of some subphrenic abscesses, and this becomes all the more obvious when you consider the varieties, shape and size which this form of abscess may assume and the different positions it may occupy. Subphrenic abscess may be defined as follows: Any collection of pus or pus and gas, the whole or part of which is between the diaphragm and the structure or organs normally in contact with it. Therefore, a knowledge of the subdiaphragmatic anatomy is essential to a proper comprehension of abscess of this region. There are no pathognomonic symptoms of this abscess. In the early stages there are generally hiccough, pleuritic stitch in the side, and friction-sounds. Later on it may give rise to dulness at the lower part of the chest on either side, accompanied possibly by a very considerable displacement of the heart. This dulness may be differentiated from a pleural effusion by the following signs,—(1) the movements of the chest are not impaired; (2) the upper limit of the dulness is not so sharply defined; (3) the breath-sounds may be heard below the level of the dulness; (4) when the pleura is not involved, in emaciated persons, the lower border of the lung may be seen rising and falling with respiratory movements, especially on the right side; and (5) in cases where gas is present, there may be a great extent of tympanic resonance. The cause of these abscesses is legion, arising either from the stomach, the intestines, the cecum, appendix, or from a general peritonitis, hydatids from the liver and bile ducts, from the kidney, subcutaneous wounds, metastasis, necrosis of the ribs, or various other causes. The article was thoroughly discussed. [G B W.]

4.—Bidwell reports 4 cases of **pyloroplasty for cicatricial contraction of the pylorus**. In 2 of these cases the stenosis was due more to spasm than to the formation of fibrous tissue. The result in all 4 cases was most satisfactory, especially in the last 2. The change from emaciated and debilitated patients to persons of practically normal health, was most pleasing. Pyloroplasty is eminently suited for nonmalignant stenosis, and in such cases is greatly superior to either gastroenterotomy or to Loreta's operation, since in these operations there seems to be a great tendency to recurrence of the dilation due to contraction of the opening. [G B W.]

5.—Wallace says that the most common cause of **rectal stricture** is septic ulceration, and the next most common cause is probably protracted labor. Syphilis and dysentery, though thought by some to be very common as a cause for rectal stricture, are responsible for comparatively few. He says that most of the operations undertaken for relief of this most distressing condition, are of little avail. He recommends the following operation as promising great relief. A preliminary colotomy is done first, so as to enable the surgeon to wash the bowel out, and in this way keep free from fecal contract any ulceration which may be in existence above the stricture so that it may have a chance to heal.

The operation consists of dilating the sphincters, then in making a circular incision around the mucocutaneous margin and separating the gut from the sphincters and freeing it in an upward direction by dissection. Slight traction is made until healthier gut appears at the anal opening and the loosened portion of the rectum may be excised. In the 2 cases reported in which this operation was done, the patients made perfect recoveries. [O W B.]

7.—Bennett concludes his article on **simple fractures** briefly in the following conclusions: He says that fractures today are treated too much upon lines which are traditional rather than rational, and that the use of splints for long periods is disadvantageous to early movements of joints below and above the fractures of long bone. The legitimate scope of operative treatment of simple fractures should be confined to those cases which are not otherwise manageable, such for example as certain spiral and oblique fractures, mainly of the tibia, and certain fractures near joints in adults, notably the elbow. The operative treatment of recent fracture of the patella is by no means so generally satisfactory or so free from risk as published cases would tend to show. The immediate use of massage and passive movements, in the majority of cases, affords the best means of effecting a rapid and useful recovery. Marked displacement of the fragments, provided that it is not rotary, is not necessarily followed by disability, especially if care be taken by use of early movements to prevent any matting of the parts around the fracture. He further says that the disability which follows in certain cases, in which the position of the united fragments is not ideal, is due, not to the bony deformity, but to the adhesiveness of the soft parts around them, and which is easily preventable. [G.B.W.]

8.—Barton says that for the **removal of large stones from the bladder**, the 2 operations to be thought of are suprapubic lithotomy and perineal lithotripsy. The advantages of the former are, that the bladder can be freely opened and examined fully in an almost bloodless manner, and a stone of any known size extracted with the least disturbance to the patient, and in cases of enlarged prostate, these advantages are accentuated. The disadvantages are that the wound may be long in healing, and the occurrence, probably from faulty stitching, of a phosphate crust on the scar reproducing another stone. The advantages of perineal lithotripsy are that the bladder-wall is not cut, and the neck of the bladder is incised only enough to admit the finger. The disadvantages of this method are the bruising of the neck of the bladder, and of the mucous membrane; the impossibility of examining in case of deep pelvis, and the difficulty of manipulating the instrument where there is a large prostate, and the danger of acute pyelitis and nephritis which is increased in proportion to the amount of manipulation. Barton concludes, therefore, that suprapubic operation is by far the best for large stones. [G.B.W.]

10.—Cross says that there are two forms of **glaucoma**. First, the chronic inflammatory, in which immediate operation by sclerotomy is imperatively demanded. Second, simple glaucoma in which some physicians believe in medical treatment and postponement of operation, but progressive simple glaucoma will sooner or later be complicated by atrophy, and if the operation is to be of service, it should be done before the limitation of vision approaches dangerously near the center of the field. The operation of choice is iridectomy, and though improvement is not always immediate, it will ultimately take place. Sclerotomy is of service only in early stages. The paper was earnestly discussed. [G.B.W.]

11.—Stephenson sums up his remarks on **phlyctenular affections** of the eye, briefly as follows: Phlyctenular disease is remotely due to a tuberculous diathesis and immediately to eruption of eczema upon the surface of the eyeball. [G.B.W.]

1.—Lister calls attention to the fact that his father deserves the credit for raising the compound microscope from little better than a scientific toy to an important instrument in medical diagnosis. He recounts some interesting experiments which he began as a student to determine the nature of pyemia and which he continued in later life. These researches to a considerable degree influenced him in adopting local measures to diminish the risk of communicating contagion from one wound to another. He first employed the sulphite of potash internally, following the recommendation of Polli. This drug was supposed to have antiputrescent qualities. Later he freely employed antiseptic washes. But he tells us that his efforts were abortive, for at that time he believed, with most chemists, that putrefaction was caused by the oxygen of the air. And it was not until Pasteur's demonstrations that he found that the problem of surgery was not to exclude oxygen from wounds, but to protect them from the living causes of decomposition. [M.B.T.]

4.—Morris describes two varieties of **aneurysm of the renal artery** following injuries. Small sacciform aneurysms, the walls of which are formed by some or all the coats of the artery, and large false aneurysms, the walls of which are composed of condensed fibrous tissue developed around extravasated and coagulated blood. He discusses the literature of the subject of aneurysms of the renal artery thoroughly, giving abstracts of all cases which have thus far been reported. The aneurysms of nontraumatic origin are of much the same form as the traumatic aneurysms. He has succeeded in collecting in all 19 cases of renal aneurysm; 7 were spontaneous and 12 traumatic. Of the traumatic cases 10 were in men, occurring mostly during the period of active life; of the spontaneous cases all the patients were over 40 years old. The traumatism causing this condition were of various kinds, mostly from injuries to the loin of the side of the diseased kidney. Of the spontaneous cases, multiple embolisms, calcareous degeneration of the coats of the arteries and nephritis are mentioned as possible etiologic factors. As long as a sacciform aneurysm remains unruptured it does not produce pathologic changes in the kidney. It may burst, causing hemorrhage into the pelvis of the kidney or true hematuria. By pressure it may cause partial or complete atrophy, or by infiltration beneath the capsule of the kidney it may cause stripping up of the capsule and possibly rupture. In some cases the kidney becomes extensively adherent to neighboring structures. The contents of the sac are usually blood-clot. Unruptured sacciform aneurysms give rise to no symptoms; false aneurysms, whether traumatic or spontaneous, nearly always cause hematuria. Among other symptoms are mentioned tumor, which was detected in 14 out of 19 cases during life. Pain which is not generally severe nor is the tumor usually tender on pressure or at the seat of acute pain. Discomfort or dull aching sometimes is felt if the tumor attains great size. Hematuria is a very common symptom next in importance to tumor. Pulsation is usually absent. Few observations have been made as to the presence of bruit and it has not been usually detected. Except for the presence of blood the urine is usually normal. There may be dysuria and frequent micturition when blood-clots are passing. The general symptoms are due to loss of blood and the effects of pressure. A diagnosis is absolutely impossible except by exploratory operation in case pulsation is absent. The prognosis is most unfavorable in false aneurysms, all the patients which have not been operated upon having died. Profuse hemorrhage is usually the cause of death. The only prospect of saving life is by nephrec-

tomy. The operation is in most cases begun as an exploratory incision. A lumbar incision, if made, must be prolonged considerably afterwards and if the tumor is very large transperitoneal operation is preferred. The whole pedicle should be secured or at any rate the renal artery should be ligated before attempting to remove or empty the sac. The risks of operation are from hemorrhage, shock and adhesions. When tough adhesions are present entire separation of the cyst should not be attempted. As much as possible of the sac should be removed and the rest left and drained. [M.B.T.]

5.—West reports the case of a man, aged 36 years, who was suffering from insomnia, dyspnea, and acute headache. His father had died from Bright's disease. Three weeks before West saw him, the patient had what he thought was influenza. At the commencement of the attack his face, neck, hands, and wrists were puffy. There was no ascites nor edema of the legs or of the body. The pulse was 84 and small, and the arteries were soft and compressible. The urine was smoky, blood and casts were present, and about $\frac{1}{2}$ of albumin was apparent on boiling. The quantity of urine in 24 hours did not exceed 20 ounces. Later the patient was suddenly seized with a violent uremic fit which lasted about 15 minutes, and left him in a semicomatose condition. Under diet, digitalis, spirit of nitrous ether, solution of citrate of ammonia, pilocarpin, venesection, and oxygen inhalations, the patient gradually recovered. The oxygen inhalations were originally given to relieve dyspnea, but they were continued after the symptom had disappeared, because they seemed to act as an antidote to the toxins in the blood. [J.M.S.]

6.—Neave reports the case of a man who died from anthrax. The source of infection is supposed to be bone-dust that the patient was using for manure in his grain field. The case pursued a very rapid course, death taking place on the fourth day. The temperature did not rise above 100°. The lesion was situated in the left side of the chest and had evidently been produced by scratching. There was no pain connected with the disease and no severe constitutional symptoms. There was also absence of mental distress. [J.M.S.]

7.—Wybauw is of the opinion that in chlorosis the increased area of cardiac dulness may be due to a true dilation of the heart as well as to displacement of that organ by upward pressure of the diaphragm. When dilation exists the apex beat is displaced downward and outward. On the other hand, when there is displacement only, the apex beat is pushed outward and upward, so that it may be felt in the fourth interspace. [J.M.S.]

8.—A case of hydatid cyst of the liver, with a capacity of 25 ounces, is reported. A remarkable symptom was diminished urination. There was also swelling of the legs and passage of blood by the bowel, probably because of obstruction of the portal vein. The cyst was emptied by crucial incision, syringed out and drained. [M.B.T.]

9.—A case of intussusception is reported occurring in a female child, 5 months old. The child had been ill for 5 days with abdominal tumor and a history of passing blood and mucus by the stool. Her general condition was good. The intussusception was in the lower part of the descending colon. It was double, the ileum entering the upper end and the rectum the lower end. Attempts at reduction were unsuccessful until the bowel was opened by a longitudinal incision. [M.B.T.]

10.—Roberts reports a case of cesarean section upon which he remarks as follows: Cesarean section was performed in this case because the pelvic cavity was blocked by a fibroid tumor of the uterus so that the conjugate diameter was reduced to $1\frac{1}{2}$ inches, rendering even cephalotripsy impracticable. The tumor sprang from the posterior wall of the uterus, and it was intended to remove it at the time of the operation, but it was found to be so firmly adherent to the rectum and the sigmoid flexure as to prohibit any further interference. The uterus was not drawn through the abdominal wound until it had been opened and emptied of its contents. This procedure allows of more easy manual compression and thus prevents hemorrhage; it also facilitates accurate suturing of the uterine wall and a thorough cleansing of the abdominal and pelvic cavities. The sutures used were of silk and they were passed through the peritoneum, the uterine muscle, and the mucous membrane. No abdominal or pelvic drainage was adopted, but the uterus

was packed with gauze through the vagina. The acute sepsis which occurred was, in his opinion, benefited by the injection of antistreptococcus serum. The patient's temperature was not normal throughout the day until about 6 weeks after the operation, after which she steadily improved. The uterus shrunk to a hard mass quite fixed in the pelvis. The child was fed artificially and is healthy. [W.K.]

2. The Present State of our Knowledge Concerning the Cause, Nature and Treatment of Asthma. WALTER A. WELLS.
3. Electrolysis in the Treatment of the Lachrymal Passages. L. L. MIAL.
4. A Combined Aspiration and Injection Instrument for Sub-arachnoid Cocainization. GEORGE RYERSON FOWLER.
5. Ballous Enlargement of the Middle Turbinate Bone (Concha Bullosa). J. PAYSON CLARK.
6. Disturbances of Gastric Motility and their Significance. ANDREW MACFARLANE.
7. The Subarachnoid Injection of Cocain. J. E. MASSEY.

1.—Grant concludes his article on the treatment of acute and chronic inflammation of the lymph nodes of the cervical region as follows: The cause of tuberculous adenitis of the cervical region is almost always local, and takes place through the buccal cavity. A suppurating gland is always dangerous, and should be removed *en toto*. Small groups or single, slowly growing glands are likewise to be removed. Nature will provide a new and equally perfect protection against external invasion, to take the place of the glands that are lost by operative procedures. [G.B.W.]

2.—As a result of his studies on the cause, nature, and treatment of asthma, Wells concludes: 1. That asthma has so many points of resemblance with migraine, angina pectoris, and epilepsy that the suspicion may reasonably be entertained that they all have a similar pathology. 2. That of the theories that have been advanced to explain the pathogenesis of the asthmatic paroxysm, no one of them so well harmonizes all the facts as the vasomotor theory; and this only when we admit that the disturbance is essentially that of arterial contraction, rather than dilation. 3. That there is always present in asthma a morbid constitutional state, affecting especially the sympathetic nervous system and giving rise to a certain nutritional aberration, whose most salient feature is the increase of uric acid and the urates. 4. That asthma occurs as a reflex neurosis from diseases of different organs, but especially often from those directly supplied by branches of the vagus nerve. The nasal trouble, which is the most frequent reflex cause, is not necessarily an obstruction, and may be very inconspicuous and difficult to detect. 5. That nearly all cases of asthma show evidence of a pronounced psychic element, as in the curious variety of exciting causes of the attack, in the capriciousness of its course and behavior, and its dependence upon emotional states and suggestion. 6. That in the treatment of the paroxysm of asthma, a strict individualization needs to be observed. The best remedies are those that overcome arterial spasm, such as morphin, nitroglycerin, atropin, and chloral. 7. That treatment in the intervals of the attacks must be directed, in the first place, to the removal of the cause, and in the second place, to the institution of sound hygienic and prophylactic measures in relation to the mind, diet, air, and exercise. 8. That medicinal treatment should be addressed to the improvement of the constitutional state, for which the best remedies are piperazin, potassium iodid, and the other iodids, the alkalies, and general tonics. [J.M.S.]

3.—Mial says that electrolysis is the most useful procedure in cases of stricture of the lachrymal passages. In regard to the technic, it seems useless to slit up the canaliculus, as a fine conical electrode can, in almost every instance, be introduced into the punctum. The chief indication in lachrymal obstruction is to get the passages open and keep them open. Electrolysis does this speedily, painlessly, and without hemorrhage, and, furthermore, is antiseptic in its action. The strength of the current should not exceed 3

milliamperes. The positive pole is best placed at the back of the neck. Frequent and short sittings, less than 2 minutes, are preferable to longer ones a week apart. [G.B.W.]

4.—Fowler has invented a combined aspiration and injection instrument for **subarachnoid cocainization**, which consists essentially in a double needle, the inner one of steel, and capable of being projected beyond the outer one of platinum. A glass bulb can be readily attached, and into this the cerebrospinal fluid can be readily drawn by means of a vacuum induced by a rubber bulb. The glass bulb is easily detached and a glass syringe put in its place for the injection of the cocain solution. The inner needle can be readily withdrawn and in case of clotting or other obstruction is easily cleaned. The cerebrospinal fluid entering the glass bulb readily announces the entrance of the inner needle into the subarachnoid space. [G.B.W.]

5.—Clark reports 2 cases of **bullous enlargement of the middle turbinated bone**. The symptoms in the first case were headache, some loss of smell, and nasal obstruction. The turbinate was removed by a cold wire snare and the patient was greatly improved. Four months after the operation nasal respiration was clear, there were no headaches, and the sense of smell was much more acute. An examination of the bone removed showed the cavity lined with several layers of columnar epithelial cells, some of them ciliated. There were no signs of inflammation. In the second case, the symptoms were occasionally headache of a neurasthenic type, which had lasted for several years; lately they had increased to severe pains in the side of the face, which remained unrelieved by correction of refractive errors of the eye and general medication. After removal of the bullous turbinate the symptoms continued apparently unabated for a week, and then began to diminish rapidly and in a week more had disappeared. [G.B.W.]

7.—Massey reports a case of **cocainization of the spine** in which 30 minims of a 2% solution of cocain were injected in the subarachnoid space, and 12 minutes later operation begun. The operation was for the cure of hemorrhoids and was done by ligation. It lasted 1½ hours and 10 double and 20 single ligations were used in tying off the hemorrhoids, and the margin and floor of an ulcer in the rectum was lightly touched with lunar caustic. During the whole of the operation the patient said he experienced no pain and the total anesthesia of the lower abdomen and extremities lasted ½ hours after the operation was completed, making 5 hours in all. Nine days after the operation the patient was walking around free from pain. [G.B.W.]

6. The Soldier's Ration in the Tropics; Its Use and Its Abuse. LOUIS L. SEAMAN.

1.—Corning mentions his experiments in **spinal anesthesia**, the first ever done in that line, and published in the *New York Medical Journal*, October 31, 1885. This he believes entitles him to the credit of priority for this discovery. The following are some points mentioned as essentials in technic in this method of reducing anesthesia: The needle, 3½ to 4 inches in length, should be fine, not overtempered, beveled, short, so that it will not require to penetrate the membranes far, to insure deposit of the solution within them. The needle may be made of gold or platinum, which being bendable is not liable to break, even when the caliber is small. A movable nut which may be fixed with a set screw regulates the depth of puncture. When the needle is thrust in, and a few drops of the cerebrospinal fluid emerge, this nut is slid down till its lower aspect rests upon the skin. It is then fixed by tightening the screw, and a further entrance of the

needle into the spinal canal effectually prevented. A syringe of glass, graduated up to 30 minims or more, provided with an asbestos packing, is best because so easily sterilized. Many of the needles recently employed are too large. The puncture which they make in the membranes allows too much cerebrospinal fluid impregnated with the anesthetic to flow out, after withdrawal of the needle. Special care as to antiseptics and asepsis of everything connected with the operation is enjoined. A 2% cocain solution which may be sterilized is usually preferred as an anesthetic. To make the injection: If possible the patient should be placed in a sitting posture, inclining forward so as to bend the spine, and separate the vertebrae. Puncture between the second and third lumbar vertebrae is recommended. The needle should be introduced slowly, the direction being slightly from without inward and from below upward. Any obstruction of its lumen may be cleared with the stylet. The outflow of a few drops of cerebrospinal fluid will tell of the penetration of the membranes. The syringe may now be attached, and the injection made. Even though the needle be small it should not be withdrawn immediately after the injection has been made; but should be maintained in place till the advent of anesthesia. By so doing the opening made by the needle in the membranes is effectually plugged, and hence the anesthetic cannot possibly flow out till it has done its work. Plunging hither and yon and sawing with the needle are to be avoided. Better withdraw the needle and begin anew, than risk the tearing of the membrane. At present from 10 to 15 minims of a 2% solution of cocain at a dose seem to give satisfaction. When the heart's action is feeble or irregular, a small dose of strychnin, nitroglycerin, and digitalin may be exhibited hypodermically a short time before the cord is anesthetized. In spite of the greatest care in technic the anesthesia is sometimes unsuccessful. Corning cautions against expecting too much from the method; he does not believe that general anesthetics will be displaced by it and thinks there may be possible remote disastrous results from its use. [M.N.T.]

2.—Horsley reports a case of **necrosis of the entire shaft of the tibia** in a female child 20 months old. The sequestrum was removed, slow recovery resulted and a useful but slightly bowed leg has resulted. [M.B.T.]

3.—Davis advises a close observation of a **patient's condition** during the weeks previous to confinement, and a careful study of the clinical symptoms of toxemia with chemical examinations to ascertain the state of the excretory processes. If these processes are defective, he thinks no drug so efficiently influences the throwing out of solid waste in the body as calomel. In doses of ½ grain, night and morning, or in smaller doses, ⅓ grain, 3 times daily, it is most successful. It is sometimes necessary to supplement this by salines, while others do as well upon this drug only. Under its use the percentage of solids in the urine increases, the percentage of urea is distinctly increased, the pulse-tension is lessened, the patient's symptoms are much improved, and her condition is very greatly benefited. If the patient complains of insomnia, restlessness, and headaches, this treatment is far preferable to the use of anesthetics, and gives more permanent relief. The physician should assure himself that there are no indications of infection of any kind, and if such infection exist, there should be thorough disinfection with green soap, mercurial or bichlorid solutions, or lysol, or carbolic acid. The presence of a serious heart-lesion in the patient, of advanced kidney-disease, and of any condition seriously interfering with the circulation of the blood through the abdominal viscera, predisposes to hemorrhage in the later months of pregnancy, and must put the obstetrician on his guard. [W.K.]

4.—Piffard has used the **tertiary current** in the treatment of **chronic eczema** with infiltration, acne rosacea, local pruritus, pityriasis capitis, localized seborrheic eczema and seborrhea oleosum. In his condition he found that resolution of the lesions took place more rapidly than under any other treatment previously used. He describes the instrument which he has had made for use in treating skin diseases. [D.L.E.]

5.—Jones emphasizes the following points regarding the **surgery of the gall tracts**: The diagnostic value of the point of maximum tenderness over the gallbladder at or near the costal margin of the ninth rib. This point in disease of the gall tracts he thinks corresponds in importance with

McBurney's point in disease of the appendix. The diagnostic value of the presence of bile in the urine during or immediately after brief obstruction of the common duct. The fact that disease of the gall tracts is of very common occurrence, and is liable to be mistaken for other troubles which it closely imitates. He urges the importance of these troubles and of their early recognition. The physician should familiarize himself thoroughly with their symptomatology, and train himself to recognize them promptly. The time is not remote when it will be as much a matter for censure to fail to recognize the presence of disease of the gall tracts as it now is to overlook that of the appendix. [M.B.T.]

6.—Seaman states that in his opinion most of the diseases affecting soldiers in the tropics are the result of rations excessively rich in meat and other foods that aggravate gastroenteric disturbance, together with the use of too large quantities of food. He states that the energy of the rations in caloric units averaged about 4,448, while the rations of the British soldier in temperate climates is only about 2,800 caloric units. In his postmortem examination he found in almost all cases congestion of the liver, a great deal of thick, tenacious mucus, over the surface of the stomach and intestine, the mucosa was hypertrophied, often ulcerated, the glands frequently atrophied. A comparison of the United States ration with that of natives of the tropics shows that it contains an excess of nearly 6 grams of nitrogen, nearly 180 grams of fat, and of over 1,500 caloric units, while there was a deficiency of over 80 grams of carbohydrates. Seaman recommends that fresh meat, being perishable, should be largely replaced by dried and smoked meats, which are to some extent stimulants and disinfectants of the gastroenteric tract. Salt and tinned meats are objectionable. Carbohydrates should be used as largely as possible, as they easily yield their energy. Fats are not well tolerated in large quantities as a rule. The value of sugar is great, and is not yet thoroughly appreciated. Tea can easily be transported, and if taken in weak infusion is not harmful, is refreshing, and furnishes a pleasant means of taking large quantities of sterilized water into the system. A ration which Seaman suggests is 10 ounces of fresh meat or an equivalent amount of dried or smoked beef, 2 ounces of bacon, 12 of flour, 4 of rice, lentils or maize, 14 ounces of succulent green vegetables, 2 ounces of dried fruit, 4 ounces of sugar with chocolate, and also tea and condiments, the whole representing about 15 grams of nitrogen, 83 of fat, 540 of carbohydrates, and yielding about 3,300 caloric units. If the men are on the march the bulky carbohydrates could be entirely replaced by sugar. It is always best to have the men frequently indulge in fresh fruits and vegetables en route if possible. [D.L.E.]

1. Some Remarks on the Pathology and Surgical Treatment of Urinary and Urogenital Tuberculosis. SAMUEL ALEXANDER.
2. Progressive Pernicious Anemia. ALFRED STENGEL.
3. Treatment of Typhoid Fever. STEPHEN SMITH BURT.
4. Increasing the Therapeutic Value of Cod-Liver Oil by the Addition of Free Iodin and Free Phosphorus. LOUIS J. LAUTENBACH.

1.—Tuberculosis of the urogenital tract may be either secondary to a tuberculous focus in the lung or other portion of the body, or it may be seemingly primary, affecting some part of the genitourinary tract from the outset. In this latter form it is generally chronic and is of especial interest to the surgeon. As to the etiology, the tubercle bacillus may gain access to these organs by an ascending infection, but in the majority of cases the disease is of hemic origin. It is possible for a tuberculous epididymitis to exist alone, but usually it is associated with more or less involvement of the prostate or of the prostatic urethra. Infection of the bladder is almost always secondary to a primary focus in the kidneys. In case of tuberculous epididymitis it is probably best, when the epididymitis alone is the seat of the disease and even in cases where there seems to be slight involvement of the prostate, to be conservative in our operating, provided the testicle itself be healthy. When the

testicle proper is the seat of the tuberculous process, castration with the removal at the same time of the seminal canal is the only operation to be considered. Primary tuberculosis of the prostate does occur and is far from infrequent. In these cases, the diseased portion of the prostate should be removed as completely as possible. [O.B.W.]

2.—Stengel gives a general discussion of **progressive pernicious anemia**. This he regards as a disease resulting from the rapid destruction of the blood-corpuscles, which the blood-making function cannot replace. The gastro-intestinal tract is evidently a source of the hemolytic agent. It is possible that in some cases the hemogenetic function of the bone-marrow is perverted. Stengel admits that, strictly considered, pernicious anemia is not a disease, but merely a systematic disorder of the blood. He quotes with approval the description given by Addison, adding a few points that have been noted since, particularly the fever and the gastro-intestinal disorders. He does not agree with Ehrlich, that the presence of megaloblasts in association with megalocytes are sufficient proof of the nature of the disease, having observed the same condition in 2 cases of leukemia during the aleukocytotic intervals. There is no pathognomonic symptom, and each case must be diagnosed after a careful consideration of all its features. Usually the reduction of the red corpuscles to less than 1,500,000 per cubic millimeter, and a proportionate reduction of the hemoglobin, in conjunction with other suspicious symptoms, is strong presumptive evidence. The prognosis, as far as regards recovery, is hopeless; all patients ultimately die of the disease, but almost complete remission, sometimes lasting for long periods, may occur. Curious alterations in the number of blood-corpuscles that have been observed may be explained by ascribing them to variations in the distribution of the corpuscles. [J.S.]

3.—Burt believes that **typhoid fever** should be treated **individually**, and not according to fixed rules. Absolute rest in bed is essential, the food should be light, preferably fluid. The best stimulant is alcohol, but it should be given with discrimination. Sponging is usually preferable to tubbing; any form of treatment requiring subsequent stimulation being bad. The Woodbridge treatment is inefficient, and the coal-tar antipyretics are dangerous. [J.S.]

4.—Lautenbach, with the aid of a pharmacist, has devised a preparation of **cod-liver oil** which contains 95% of the oil, and in each ounce, $\frac{1}{2}$ grain free iodine and $\frac{1}{10}$ grain of free phosphorus. This preparation keeps well, but in the course of time undergoes hydroxylation. It is said to be particularly beneficial as a tonic, and superior to the ordinary preparations. [J.S.]

Boston Medical and Surgical Journal.

October 18, 1900. [Vol. cxliii, No. 19]

1. Suppurative Pericarditis and Its Surgical Treatment. The Surgical Anatomy of the Pericardium. Conclusions. CHARLES B. PORTER.
2. Hydrotherapy in Pneumonia. SIMON BARUCH.
3. To What Extent Does "Rheumatic and Gouty Diathesis" Enter Into Traumatic Joints (Sprains and Bruises), Septic and Gonorrheal Joints, Acute Articular Rheumatism, Neuropathic Joints, Arthritis Deformans (Osteo'd, Rheumatoid), as an Etiologic Factor? What is the Scientific Basis for Such a Term? WILLIAM H. PORTER.
4. Septic and Gonorrheal Joints. CHARLES A. PORTER.
5. Neuropathic Joints. SIDNEY A. LORD.

1.—Porter states that 3 methods of operation for suppurative pericarditis have been proposed and practised: By trephining the sternum, by incision through an intercostal space, and by epigastric incision. All of these he thinks should be discarded, because of the danger of wounding the pleura or diaphragm. The ideal operation should avoid opening the pleural cavity; open the pericardium opposite the point where drainage will remain good after the sac has contracted, and secure permanent free drainage. He recommends the following operation as fulfilling these conditions: An incision is made from the middle of the sternum outward over the fifth costal cartilage to its junction with the rib. The soft parts are cleaned off with a periosteal elevator and the

cartilage is divided from the rib and sternum with bone forceps. The internal mammary vessels are exposed and should be ligated in 2 places. If fat is encountered, careful dissection with a director exposes the pericardium. An aspirating needle should be introduced to establish the diagnosis and the pericardium then opened by incision obliquely downward and outward, beginning close to the excised border of the sternum. The edges of the pericardium are stitched to the soft parts. Irrigation should always be employed to remove masses of fibrin. Drainage is best provided by 2 rubber tubes, one reaching the bottom of the sac and a short tube just entering the sac. As the discharge diminishes, one tube may be removed and finally gauze drainage inserted. When thick or flocculent fluid is present the tubes are the only adequate means of drainage. Daily irrigation is practised. The subsequent treatment consists in forced feeding and free stimulation. Porter discusses the literature of the subject in a thorough manner and mentions a case in which he operated. He believes that **pericardotomy** is indicated in all cases of suppurative pericarditis. Because of the uncertain and varying relations of the pleura and of the anterior position of the heart, aspiration is more dangerous than open incision. Incision may be quickly and safely performed by resection of the fifth costal cartilage in many cases under local anesthesia. In many cases of serious effusion, open incision without puncture will offer less risk and speedier cure than aspiration. [M.B.T.]

2.—Baruch believes that the application of a **cold pack in pneumonia** meets the 4 chief indications: it fortifies the nervous system, sustains the heart, promotes the elimination of the noxious products arising from the action of the diplococcus, and renders the patient more comfortable by reducing the temperature, deepening respiration, allaying pain, and producing sleep. The technic is very simple; the compress is made of 3 folds of old coarse linen wrung out of water at 60° F. These are wrapped around the chest from the clavicle to the umbilicus, a slit being made to accommodate the shoulder, and it is then covered with a larger layer of thin flannel. The chief variation depends upon the degree of fever; if this is lower (100° to 102°), the compress should be thoroughly wrung out; if the temperature is high, it should be more thoroughly soaked, and the water used may be 65°; if the patient complains of chilliness, the compress may be allowed to remain longer without changing, becoming in time, a sort of poultice; if there is cyanosis, or other indications of a depressing effect, treatment should be modified, or even suspended, although it is desirable not to do the latter if possible to avoid it. The only unfortunate effect, if it can be called such, is the prolongation of the period of resolution. [J.S.]

4.—Porter discusses the bacteriology and pathology of septic and **gonorrheal joints**; also their symptomatology and course and reports several cases. He believes that the gonococcus alone is capable of causing arthritis which may be purulent. This may occur not only in acute gonorrhea but in chronic or latent stages which persist much longer than is commonly believed. The signs of chronic infection are often slight and disregarded or overlooked. In consequence not a small proportion of cases are diagnosed as articular rheumatism. In the treatment of this affection, irrigations of the urethra with mild antiseptic solutions are recommended together with the continued use of ice bags or dry heat, preferably with a hot oven. When pus can be demonstrated by fluctuation, edema and redness or aspiration of the joint or tendon sheaths, then only should operation be resorted to. Incision, irrigation, immediate suture without drainage is advised. As relatively few pure gonorrheal infections lead to suppuration the treatment by immobilization and early passive motion is safer for general adoption. [M.B.T.]

5.—Lord discusses the **arthropathies of tabes and syringomyelia** which occurred in from 5% to 10% of all cases of this disease. There are 2 varieties, the atrophic and the hypertrophic. It is difficult or impossible to separate these conditions from fractures of the ends of the bones; in fact, some people believe that they are entirely due to this cause; the effusion can then be explained by ascribing it to hemorrhage. The fractures can be supposed to be caused by the violent movement of the limbs in consequence of the ataxia, and it is also possible that there is some special atrophic disturbance in the joint which tends to render the

bones more friable. These cases are ordinarily very readily diagnosed. Other forms of this disease are observed in neuritis and in hemiplegia. The osteoarthropathy of pulmonary origin described by Marie is really an osteoperiostitis of toxic origin. The acroarthritides of Hutchinson in which the terminal joints of the fingers assume the tabetic deformity is possibly due to disturbed circulation. In the treatment of various forms of arthropathy little can be done. Orthopedic measures should be employed if the deformity is excessive, and surgical measures if suppuration occurs. [J.S.]

Journal of the American Medical Association.

15. Necessity of Examination of the Sputum in the Diagnosis of Pulmonary Tuberculosis. C. M. WOOD.
16. The Right of the State to Provide Hospitals. FINLEY SCRIGGS.
17. Treatment of Pulmonary Tuberculosis. JOHN M. LISLE.

2.—Dr. Lee urges the importance of the establishment of State hospitals for the treatment of the consumptive poor. [M.B.T.]

4.—Tae needs of the tuberculous patient are several, and apart from special medication include: Rest from work; change of work and cares, so as to shift the load from parts that have borne it to those that are fresh; painstaking attention to digestion and feeding and nutrition of the body; long hours of sleep; outdoor life, much sunshine, and fresh air every hour; a change of surroundings for novelty and pleasure, and to help shift the load, and finally, a change of climate, to a better one if possible, but a change anyway. Change of climate helps or ensures some of the others, but not all, and, great as climate is, it is not everything. [M.B.T.]

6.—Hinsdale gives a chart which shows that the deaths from tuberculosis in Pennsylvania in 10 years exceed 27,000, about equaling the combined deaths from diphtheria, typhoid fever, apoplexy, scarlet fever, smallpox, and inflammation of the stomach and bowels. Between 1870 and 1897 there was a constant fall in the number of deaths from pulmonary tuberculosis in proportion to the population, but the proportion rose slightly in 1899. In 15 years the percentage of deaths from pulmonary tuberculosis has fallen from 14% of all deaths to only 10%. This has been a great gain and a showing of which the State may well be proud, but Hinsdale believes that a still greater reduction in the rate will continue. [M.B.T.]

7.—During the past year Boland has been in communication with the boards or bureaus of health of 22 principal cities of the United States to determine what measures they are taking to regulate the spitting nuisance. He finds that special laws have been enacted in one-half of these cities, and about one-fourth are regulating partly or wholly under their general nuisance acts. These ordinances empower bureaus of health to abate or prohibit anything of an unsanitary character; indiscriminate spitting is included. He urges the importance of this reform. [M.B.T.]

8.—After making due allowances for all modifying circumstances, particularly accidental infection, including infected homes and prolonged contact with tuberculous subjects, Anders entertains no doubt that a predisposition to tuberculosis may be inherited, and this tendency is more unfailingly transmitted through the mother than the father. This increased susceptibility, which we note in a limited number of families, is dependent on a lack of resistance of the animal-cell and the latter condition in turn on a faulty metabolism or nutrition. [M.B.T.]

Wiener klinische Wochenschrift.

August 2, 1900. [13. Jahrg., No. 31.]

1. Total Exclusion of the Intestines. ERWIN PAYR.
2. A Case of Paraphenylendiamin Poisoning. EMIL POLLAK.
3. The Treatment of Necrotizing Acne with Seasalt Solution. FRIEDRICH LUTHLEN.

1.—Payr believes that it has been generally decided that **total exclusion of the intestine** is not a justifiable operation. Those who have been its advocates have been forced by later clinical experience or experimental work on animals to abandon it as a procedure for general use. However there are conditions in which it may be of use. A case of psoas and iliacus abscess is reported which was opened by an incision along the crest of the ileum and Poupart's ligament. Tuberculous pus was evacuated. A few days later an intestinal fistula developed in the abscess-wall from the cecum. This continued for 3 months. Ileocolostomy was undertaken with the hope of relieving the condition. A month later the fistula was still secreting as before. A third operation was undertaken and about 40 cm. including the entire ascending colon and a portion of the ileum was shut off from the general fecal circulation. The ends of the ileum and colon were closed by double rows of continuous sutures and end-to-end anastomosis of the ileum and transverse colon was made. Eight months after the operation the patient is in a very much improved condition and there is no evidence of any untoward symptoms. This operation was undertaken in this case because the feeble condition of the patient made it inadvisable to do a more extensive operation. [M.B.T.]

2.—**Paraphenylendiamin** is a poisonous substance used in the preparation of certain hair dyes, particularly one known in Europe as **Phenix**. The author's patient had used it for the purpose of dyeing gray hairs. After the third application she developed an extensive eczematous eruption of the scalp and forehead, lachrymation, injection of the conjunctiva, and edema of the eyelids. Subcutaneous injection of paraphenylendiamin into rabbits produced symptoms similar to those seen in the woman; but in some of the animals the acute symptoms subsided and a chronic form of poisoning developed, characterized by vomiting, diarrhea, and hematuria, followed by clonic or tonic spasms ending in coma and death. The test for paraphenylendiamin is that of Lauth; by the oxidation of the substance in an acid, hydrogen sulfid containing solution with chlorid of iron, Lauth's violet—a greenish-black, iridescent powder—is produced. This powder is soluble with difficulty in cold water, but readily soluble in boiling water, with a development of a violet color. [D.R.]

3.—The author has had success in 2 cases of **inveterate necrotizing acne** with applications of **sea-salt** in the form of compresses (1.2% solution) and ointments of similar strength. In addition full baths in sea-salt water were taken. [D.R.]

August 9, 1900. [13. Jahrg., No. 32.]

1. Additional Cases of Traumatic Tetanus, which were Treated with Subcutaneous Injections of Brain Emulsion. ANTON KROKIEWICZ.
2. The Hot Springs of Monfalcone. E. LUDWIG and TH. PANZER.
3. Total Exclusion of the Intestine. ERWIN PAYR.

1.—The unsatisfactory results which have followed from the serum treatment of traumatic tetanus led Krokiewicz to try the results of **brain emulsion** in such cases. He reports 2 cases which were satisfactorily treated in this way. An emulsion made from an entire rabbit's brain was injected

subcutaneously, the injection being repeated in the first case 4 times. Krokiewicz believes that the results thus far from the injection of brain emulsion in cases of tetanus are more favorable than after most other methods of treatment. Thus far 8 recoveries and 2 deaths have been reported and in all of these cases suitable drugs had been tried without result. He believes that the emulsion deserves wider application. [M.B.T.]

3.—**Total exclusion of the intestine** is a rare operation, but Payr believes that in some cases it offers the only way to make life bearable for certain patients. Salzer has given 3 indications for the operation: Fecal fistulas after injuries and acute and chronic diseases of the intestine; intestinal fistulas resulting from inoperable tumors or erosion of the intestine in consequence of suppurative processes within the abdominal cavity; stenotic processes in and about the intestine in which it is impossible to resect or to form an artificial anus. He reports a case which was operated upon for the second indication—a suppurative process within the abdominal cavity. After careful search of the literature he finds no case in which this indication, which was given theoretically, has been practically applied before this. The patient had received a gunshot wound in the right inguinal region, causing an intestinal fistula. There also developed secondarily chronic osteomyelitis of the ilium, probably of tuberculous nature, with an abscess in the right inguinal region. Removal of the projectile, incision of the abscess, and extensive plastic operations were undertaken without result. Erosion of the intestine was produced. In the first operation a communication between the cecum and the abscess-cavity was closed. Later, lateral ileocolostomy by means of sutures was carried out with a fairly satisfactory result. [M.B.T.]

Berliner klinische Wochenschrift.

August 6, 1900. [37. Jahrg., No. 32.]

1. Reality and Significance of Ganglion-cell Changes Especially in Psychoses. E. MEYER.
2. Observations on Diabetes Insipidus. H. REBENSBERG.
3. Bacteriology of Whooping-cough. G. ARNHEIM.
4. An Idiopathic Passing Disturbance of Consciousness. PLACZEK.
5. Primary Sarcoma of the Stomach. W. MINTZ.

1.—Meyer has studied the brain in a number of **psychoses** both acute and chronic. Portions of the central convolutions were hardened in formol-Müller and stained with thionin on neutral red. His conclusions are that **changes in the ganglion cells are not constant** and may be absent even in those that are characterized by fulminant symptoms. The changes found are practically the same, regardless of the nature of the mental disease, nor are they to be distinguished from those observed under entirely different conditions; in other words, **specific cell changes are not demonstrable in insanities**. [D.R.]

2.—A lengthy report of 2 cases of **diabetes insipidus**. No remedy seems to be of any value, but some amelioration was observed, which could be attributed to an improvement in the general health, outdoor life, and a moderate restriction, without coercion, of the amount of fluid ingested. [D.R.]

3.—Arnheim in a considerable number of cases of **whooping-cough** was able to demonstrate, both in the sputum and, in fatal cases, in the lung, the **pole bacteria** described by Czaplewski. He was not able by means of pure culture to produce whooping-cough in the lower animals, but the organism proved pathogenic to white mice, particularly after intraperitoneal inoculation. [D.R.]

4.—A woman of 40 years, while conversing with a relative suddenly began to wring her hands and to moan, saying that she had lost her memory. She asked a number of strange questions, complained of a torturing anxiety, saying that if she at that moment should commit murder she would be guiltless, as she did not know what she was doing. After about 6 hours her mind became clear, but there was a total amnesia regarding the peculiar attack. Twenty-four hours later a severe migraine developed. On the day on which the mental disturbance took place the patient's menses set in and (upon which she laid considerable stress) there was a thunderstorm. There were no hysteric stigmata. The second case concerned a fireman on a locomotive who, while

returning from an excursion, suddenly began to resist the entrance of his friends into the railway compartment and was angry and insulting, but gradually became quiet, although refusing to answer any questions. On his return to his home he had no knowledge whatever of what had taken place immediately before. He had not been drinking. The interpretation of these cases is difficult, but Placzek does not think that epilepsy or hysteria can be drawn upon for their explanation. He considers them as **idiopathic, transitory disturbances of consciousness**, and cites a few analogous cases from literature. [D.R.]

5.—The subject of **sarcoma of the stomach** is discussed and brief abstracts are given of 5 cases which have been reported since Schlesinger collected 36 cases of this disease. A case is reported occurring in a man of 30 who had been suffering from severe pain in the abdomen, vomiting, rapid loss in strength and weight for about a month. A large tumor was felt in the epigastrium. For the relief of his symptoms gastroenterostomy was performed. The vomiting did not cease, however, and the patient died 6 days later. At the necropsy the pylorus was found to be occupied by a hard tumor about the size of the fist. This extended into the anterior and posterior wall of the stomach. The lymph-glands of the lesser curvature were considerably enlarged. There was also metastasis in the testicle and cord. [M.B.T.]

Deutsche medicinische Wochenschrift.

August 9, 1900. [26. Jahrg. No. 32]

1. Does Alcohol Operate as a Food or as a Poison? KASSOWITZ.
2. A Form of Typhoid-like Disease Caused by Germ Resembling the Typhoid Bacilli. SCHOTTMÜLLER.
3. To the Knowledge of Right Hand and Left Hand. ADOLF HECHT and LEO LANGSTEIN.
4. Remarks on Polyneuritis Puerperalis. MINKIEWICZ.
5. The Physico-chemical Analysis of Mineral-water. HANS KÜPPE.

1.—Schottmüller has carried out a series of bacteriologic investigations of the blood of typhoid patients, and mentions from his general results the fact that in 50 cases examined he found in 40, i. e., 80%, typhoid-bacilli in blood taken from the arm during life. A case especially reported in this paper ran a course which would have been considered typhoid fever had it not been for the bacillus which was found in the blood. The onset was somewhat irregular. The man had an erysipelas-like eruption on the left hand which did not disturb his general health at first, but a few days later caused a rise of fever suddenly to 40° C., which was accompanied by catarrhal symptoms of the nasal, ocular and pharyngeal mucous membranes. There was no exudate in the throat. The subsequent course was like typhoid fever, and accompanied by an eruption of rose-spots, by enlargement of the spleen, by fall of temperature, by lysis, and the pulse was slow in relation to the fever; the bacillus isolated from the blood, however, at about the middle of the attack, showing decided differences from the typhoid-bacillus. The patient's blood-serum did not agglutinate the typhoid-bacilli in a dilution of 1 to 20, while it did agglutinate the bacilli isolated in a dilution of 1 to 50, and later in a dilution of 1 to 100. The bacillus caused gas evolution in a glucose-bouillon medium also. The nature of the bacillus was not definitely known. The author, however, considers that so-called sporadic cases of typhoid fever should be carefully investigated bacteriologically as they may prove to be other forms of infection closely related to typhoid, but not true typhoid. [D.L.E.]

3.—Hecht and Langstein have made a large series of investigations with the Gaertner tonometer. It is known that the blood-pressure is somewhat higher normally in the right hand than it is in the left. They have found this to be the case in all these examined who were right-handed. In left-handed people, however, they found the pressure higher in the left hand than in the right. Curiously enough they found in one soldier who had learned with difficulty to do the major part of his work with his right hand, and had used his right hand for years, but was naturally left-handed, that blood-pressure was still higher on the left than on the right.

The increase of blood-pressure seems to be in direct relation with the existence of **right-handedness or left-handedness**. Perhaps it is in some way causative. [D.L.E.]

4.—The case reported was that of a woman who in the latter half of pregnancy showed vomiting, and gradually developed the signs of a general polyneuritis of rather mild degree, chiefly affecting the arms. Gradually a complete cure was brought about. The disease did not become fully developed until after the occurrence of labor, and from time to time the symptoms increased between the onset of the disease and its full development, the increase being rather paroxysmal. Since it began in the course of pregnancy it should rather be called a **neuritis of pregnancy** than puerperal neuritis. There seemed to be no possibility of an infection through the genital tract in this case. [D.L.E.]

Münchener medicinische Wochenschrift.

August 14, 1900. [47. Jahrg., No. 33.]

1. The Coating of the Tongue in the Well and the Unwell. JOHANNES MÜLLER.
2. The Fitting Up of Sanatoriums for Tuberculous Children. ADOLF BAGINSKY.
3. Foreign Body in the Left Bronchus. HECKER.
4. The Treatment of Typical Pachydermia Laryngis with Salicylic Acid. JOHANN FEIN.
5. A Case of Liver Echinococcus with Rupture Into the Gall-Passage. W. ALTHAUS.
6. The Indications for Surgical Interference in Extrauterine Pregnancy. L. PROCHOWNICK.
7. The Suturing of Arteries. RUDOLF SEGGER.

1.—The coating of the tongue in health depends principally upon the degree of development of the brush-like terminations of the filiform papillas, and a true deposit plays but a small role. The development of the ends of the papillas varies greatly in different individuals, and is subject to alterations at different epochs of life. In very young children a coated tongue is rare. It is more common in older children and in adult and middle life. There seems to be a certain parallelism between the degree of development of the ends of the filiform papillas and other epidermal structures, such as the hairs and the thickness of the skin. **Coating of the tongue in disease** is more common in acute affections, whether they involve the digestive tract or not. If the tongue is scraped with a horn spatula it is found that in diseased persons a much more abundant quantity of fluid and morphologic elements is obtained than in health. In cases of cancer of the stomach and tuberculosis of the lung the author found an unusual number of leukocytes in the scrapings. The coating of the tongue in disease depends upon various factors: 1. The mechanic influence; normally the tongue is cleaned by the ingestion of solid food. In disease the tongue is more quiet than in health. 2. In some diseases there is a sort of desquamative catarrh of the tongue. In the production of this microorganisms play a part. It is probable that disturbances of the gastrointestinal tract modify the condition of the saliva, the blood-supply to the mouth, and other factors, which in turn influence the bacterial flora and produce a desquamative catarrh of the epithelium. 3. A thick coat in disease is most likely to occur in those who naturally have excessively long papillas. In the pathologic coating it is always possible to scrape off more epithelium than in the normal condition. Regarding the **therapy**, it follows from what has been said that it is useless to attempt the removal of a normal coating by scraping and scratching. Only a pathologic deposit can be removed. For the latter purposes a soft toothbrush is best. The chewing of calamus root also serves to cleanse the tongue. [D.R.]

2.—Baginsky eloquently advocates the **establishment of special sanatoriums for tuberculous children**. Cases of local tuberculosis of the skin, superficial glands, and bones, do remarkably well at the seashore; but for children with tuberculosis of the lung a quiet, dust-free woodland region is preferable. Regarding the **frequency of tuberculosis** among children, Baginsky found in 16,163 patients treated in the Kaiser und Kaiserin Kinderkrankenhaus in Berlin, 933 with tuberculosis. Of these, 543 (88.19%)

died, 335 of them of miliary tuberculosis. Of the 933, 515 had tuberculosis of the lung; 120 (12.19%) had intestinal tuberculosis. Baginsky believes in the **pavilion system** of sanatorial construction, and gives details regarding size of rooms, etc. Up to the age of 10 years the sexes can be kept together; after that, separately. Provision should be made in the sanatoriums for instruction and for the dwellings for teachers and janitors; also for gymnastic exercises. A diet list is also given. [Both in Italy and in Germany a number of public-spirited organizations have been formed for the purpose of establishing children's sanatoriums. It is to be hoped that America will not be outdone in this good work. D.R.]

3.—Hecker reports an interesting case of **foreign body lodging in the left bronchus** of a boy, 6½ years of age. The history of the case showed the child was struck a severe blow on the chest which was followed by temporary dyspnea and later by fever. At times, however, he seemed perfectly well except for pain in the left side of the chest. Almost a month after the accident the child was brought to the hospital when he presented symptoms which led to the diagnosis of chronic pneumonia, complicated by a localized empyema shut off from the general pleural cavity by adhesions. The patient in spite of all treatment grew rapidly worse, the symptoms being characterized chiefly by their great variety, until finally the development of pulmonary edema brought about death, 3 weeks after the patient's entrance into the hospital. The postmortem revealed the true state of affairs. The right lung, except for a few spots of catarrhal pneumonia and edema, was normal. The left lung, however, was gangrenous in parts and showed an interstitial pneumonia and in the supplying bronchus was found a pointed piece of lead pencil about 21 mm. long. The patient evidently had this piece of pencil in his mouth at the time of the accident and when struck had made a strong inspiratory effort which drew the foreign body down into the lung. [G.B.W.]

4.—Fein has had good success in the treatment of **pachydermia laryngis** with the local application of **salicylic acid**. He uses a solution of salicylic acid, 1 gram in 5 grams each of distilled water and alcohol. [D.R.]

5.—When first examined this patient presented symptoms resembling cholelithiasis with an acute swelling of the liver. The diagnosis was by no means certain and the discovery of a deep fluctuation in the epigastrium did not make things more clear. The patient improved, however, to such an extent as to be able to resume work, but within 3 months he was taken with another similar attack. This time there was a decided mass in the epigastrium and after a few days he passed by the rectum a number of **echinococcus cysts** as proved by the microscope. From this time on the liver began to lessen in size and the patient to improve in health. The most probable path by which the echinococcus gained access to the intestine was the gall-duct, the only other possibility being a rupture of the cyst directly into the intestine. [G.B.W.]

6.—Prochownick, in concluding his article upon the **indications for operative interference in extrauterine pregnancy**, says that all his observations of the last few years have more and more convinced him that an early and radical abdominal operation is the best and wisest conservatism; that in cases of an intact fetal sac with probable tubal abortion and considerable hematocele, or if after a pause a secondary hemorrhage sets in, he would advise an early radical operation; or if fever is associated with the extrauterine pregnancy he would urge an operation quite energetically, preferring the abdominal section, as it promises a better oversight of the technic, a more radical cure, while the danger is no greater than by the other way. But if consent cannot be obtained for the radical operation, or if the patient has not come under one's care at a suitable time, the further procedure must depend upon the course of each case. In general, he prefers a conservative course, as he thinks secondary operations give little satisfaction to either patient or physician. Here, then, lies the field for incision and drainage by the vaginal route. [W.K.]

7.—Seggel reports a case of incised wound of the carotid in which he successfully **reunited the cut walls of the artery by sutures**. The wound had resulted from an attempt at suicide with a razor. The artery was cut transversely, only part way through, and it was quite easy to pass a small curved needle through the adventitia and media

without harming the intima. To reinforce the suture a flap of connective tissue was stitched over the artery and the wound was then packed. On removal of the packing a diffuse pulsation was observed and it was thought that possibly a traumatic aneurysm had developed. There was no bruit present, however, and in the course of time the pulsation disappeared and the wound healed by granulation. During the whole of the healing process the peripheral arteries supplied by the carotid, pulsed freely, as far as could be ascertained. [G.B.W.]

Neurologisches Centralblatt.

September 21, 1900.

1. Experiments upon Staining the Neuroglia and a New Staining Method. BENDA.
2. A New Method for the Fixation of Footprints in the Study of the Gait. MÖNKMÖLLER and KAPLAN.
3. What Significance have Tabetic Symptoms in Children Suffering from Hereditary Syphilis for the Etiology of Tabes? GÖMPERTZ.

1.—Benda, having become convinced that **Weigert's neuroglia method** is too uncertain and unsatisfactory, has made a series of experiments in the staining of this substance with the object of discovering some better method. He agrees with Weigert that the tissue should be fresh, and prefers to harden it, cut in small pieces, in 10% formalin, sometimes even in pure formalin. He believes that Weigert's mordant consisting of chromalaun, copper acetate, and acetic acid is exceedingly desirable, and leaves the pieces in it at least 2 days at incubator temperature. He employs as an additional mordant a 0.5% aqueous solution of chromic acid. The tissue is then washed 24 hours in water, dehydrated in alcohol, imbedded in paraffin, and the sections fastened with albumin water. The sections after the paraffin has been removed are mordanted for 24 hours in some iron salt, preferably a 4% solution of iron alau, washed in water for a few seconds, and then stained with a weak solution of sodium sulfaluzinate followed by a .1% aqueous solution of toluidin-blue. They are then washed in 1% acetic acid, dried, dehydrated, and differentiated in creasote. This gives excellent results. The neuroglia tissue is stained a deep blue, apparently by replacing the alizarin stain, which therefore acts as an adjuvant. In addition the granules and nuclei of the cells and certain other bodies are also stained but are readily discriminated. Another method that Benda has found to give good results consists of placing the specimens after mordanting for 24 hours in a pale aqueous solution of hematoxylin, then in 30% acetic acid, and after washing staining again with anilin water, gentian violet solution, or oxalic acid methyl violet. The tissues are then treated as in Gram's method and the results are again very satisfactory. Finally excellent results are also obtained by treating the sections stained in hematoxylin with van Geisen's mixture of picric acid and acid fuchsin. [J.S.]

2.—The method consists in having the patient wear thin stockings which are saturated with a 10% solution of iron chlorid. They walk upon a roll of paper which is subsequently treated with the following solution: ammonium sulphocyanate 25, alcohol 100, and ether sufficient to make 1,000 parts. The footprints are dark reddish-brown in color. The objection to the method is that the patients walk in their wet stockings in a rather abnormal manner. A number of tracings are given of various conditions, and the authors conclude that **recording the footprints** has, among other advantages, the demonstration of certain obscure phenomena which renders them more readily studied, enables the observer to apply direct measurement of the various disturbances of gait, and corrects errors of observation. [J.S.]

3.—Gompertz reports a case of a child, 9 years of age, suffering from **hereditary syphilis**. He had hypotonia in both legs, loss of the left patellar reflex, and incontinence of urine. There was no disturbance of gait or station. There was an old chronic keratitis, but apparently no pupillary disturbance. The author is not certain that Bydinski is correct in believing this complex of symptoms is necessarily an indication of tabes, and is rather inclined to ascribe it to syphilis of the spinal column. [J.S.]

Original Articles.

THE ETIOLOGY OF YELLOW FEVER.

A Preliminary Note.¹

By WALTER REED, M.D., Surgeon, U. S. A.,

AND

JAMES CARROLL, M.D., A. AGRAMONTE, M.D., JESSE
W. LAZEAR, M.D.,² Acting Assistant Surgeons, U. S. A.

THE writers, constituting a board of medical officers, convened "for the purpose of pursuing scientific investigations with reference to the acute infectious diseases prevalent on the Island of Cuba," arrived at our station, Columbia Barracks, Quemados, Cuba, on June 25 of the present year, and proceeded under written instructions from the Surgeon-General of the Army, to "give special attention to questions relating to the etiology and prevention of yellow fever."

Two of its members (Agramonte and Lazear) were stationed on the Island of Cuba, the former in Havana, and the latter at Columbia Barracks, and were already pursuing investigations relating to the etiology of this disease.

Fortunately for the purposes of this board, an epidemic of yellow fever was prevailing in the adjacent town of Quemados, Cuba, at the time of our arrival, thus furnishing us an opportunity for clinical observations and for bacteriologic and pathologic work. The results already obtained, we believe, warrant the publication, at this time, of a Preliminary Note. A more detailed account of our observations will be submitted to Surgeon General Sternberg in a future report.

The first part of this Preliminary Note will deal with the results of blood-cultures during life and of cultures taken from yellow-fever cadavers; reserving for the second part a consideration of the mosquito as instrumental in the propagation of yellow fever; with observations based on the biting of nonimmune human beings by mosquitos which had fed on patients sick with yellow fever, at various intervals prior to the biting.

In prosecuting the first part of our work, we isolated a variety of bacteria, but of this we do not purpose to speak at present. It will suffice for our purpose if we state the results as regards the finding of *Bacillus icteroides*, leaving the mention of other bacteria to our detailed report.

The cases studied during the Quemados epidemic had been diagnosed by a board of physicians, selected largely by reason of their familiarity with yellow fever. This board consisted of Drs. Nicolo Silverio, Manuel Herera, Eduardo Angles, and Acting Assistant Surgeon Roger P. Ames, and Jesse W. Lazear, U. S. Army.

Those studied in Havana were patients in Las Animas Hospital, and had been diagnosed as such by a board of distinguished practitioners of that city.

An examination of Table I will show the character of the attacks. The milder cases studied, few in number, were attended by jaundice and albumin in the urine.

I.

Bacillus Icteroides (Sanarelli) as the Cause of Yellow Fever.—The claim of Sanarelli for the specific character of *B. icteroides* as the causative agent in yellow fever, has excited such wide attention, since the publication

of his observations, that it seemed to us of the first importance to give our undivided attention to the isolation of this microorganism from the blood of those sick with yellow fever, and from the blood and organs of yellow-fever cadavers.

A. *Cultures taken from the Blood during Life*.—The method followed was that ordinarily used in an attempt to isolate bacteria from the circulating blood; viz., from a vein at the bend of the elbow, a sufficient quantity of blood was taken with an hypodermic syringe, made sterile by boiling, and after careful cleansing of the skin with soap and water, followed by equal parts of absolute alcohol and ether, and 1:2000 bichlorid solution.

Exceptionally the blood withdrawn was plated on agar, but, as a rule, it was immediately transferred to sterile bouillon tubes (10 ccm.) in quantities of 0.5 ccm. to each of several tubes. These were then incubated at from 35° to 37° C. for a period of one week. They were examined daily and if growth was observed, plates in agar or gelatin, or both, were made and the colonies carefully studied by transference to ordinary laboratory media.

Eighteen cases have thus been carefully studied; of these 11 were designated as "severe" cases of yellow fever with 4 deaths; three as "well-marked" cases with no deaths, and 4 as "mild" cases with no deaths.

From these 18 cases, blood-cultures were made, as shown in the following table:

TABLE I.

BLOOD-CULTURES DURING LIFE.

DAY OF DISEASE.	CHARACTER OF ATTACK.	NO. OF CULTURES.	NO. OF BOUILLON TUBES INOCULATED.	BACILLUS ICTEROIDES.
1st	Severe.	3	4 (3 agar plates.)	Negative.
"	Well marked.	1	4	"
"	Mild.	1	3	"
2d	Severe.	6	18	"
"	Well-marked.	1	2	"
"	Mild.	1	3 (6 agar plates.)	"
3d	Severe.	7	18 (6 agar plates.)	"
"	Mild.	2	4	"
4th	Severe.	5	14	"
"	Well-marked.	2	6	"
"	Mild.	1	1	"
5th	Severe.	5	12 (3 agar plates.)	"
"	Well marked.	1	3	"
"	Mild.	1	1	"
6th	Severe.	4	6	"
"	Well-marked.	1	2	"
7th	Severe.	1	2	"
"	Well-marked.	1	2*	"
8th	Severe.	2	6	"
"	Well marked.	1	2	"
9th	Severe.	1	2	"

Number of cultures 48
Number of bouillon tubes inoculated 115
Number of agar plates 18

It will be seen that of 48 separate cultures made from the blood on various days of the disease and representing 115 bouillon inoculations and 18 agar plates

¹ Read at the Meeting of the American Public Health Association, held in Indianapolis, Ind., October 22-26, 1900.

² Died of yellow fever at Camp Columbia, Cuba, September 25, 1900.

we failed to find *Bacillus icteroides* in any of our tubes or plates.

The results of cultures taken in 18^a cases of unmistakable yellow fever, on various days of the disease, and in some cases on every day from the onset to death or recovery, would seem to exclude the presence of *Bacillus icteroides* in the blood of these cases during life.

It will, therefore, be seen that while Wasdin and Geddings, taking cultures from the ear-lobe (Report on the Cause of Yellow Fever, 1899), record that "in the blood of yellow fever cases extracted during life *Bacillus icteroides* has been found in 13 of the 14 cases, with 1 negative," (92.85%), we, by withdrawing the blood from the veins of 19 patients, have to record 100% of failures.

We have already stated that we will reserve for a later report a description of the bacteria isolated from the blood in these cases. We now remark that but few organisms were obtained and that, as a rule, our blood-cultures gave no growth whatever.

B. Cultures from Yellow Fever Cadavers.—We tried to obtain autopsies very soon after death, and sometimes succeeded in doing so. Tubes containing about 10 ccm. of flesh-peptone bouillon were generally used for the first inoculation direct from the blood and organs. As soon as the laboratory was reached, agar plates were made from these inoculated bouillon tubes, the former as well as the latter being then incubated at from 35° to 37° C. In nearly every case gelatin plates were also made from the recently inoculated bouillon tubes and kept at a temperature of 19° to 20° C.

If colonies were found in the agar or gelatin plates, on the following days, the corresponding bouillon tubes were also plated on agar and gelatin. The bacteria thus found in our plates were carefully isolated and studied upon the usual nutritive media, so as to enable us to identify them, if possible. We will here content ourselves with giving the results as regards the presence of *B. icteroides* only.

much surprised at the absence of this bacillus in cultures from cadavers sectioned in or near Havana, during the present year. In 2 of the 11 cases we had reason to believe that from the appearance of colonies seen in gelatin plates, we would be able to isolate *B. icteroides*. These colonies, however, when transferred to other media and carefully studied, did not prove to be this bacillus. We wonder whether other observers have occasionally relied upon the appearance of colonies in gelatin plates, without further study. We only mention this as a possible explanation of the large percentage of positive results recorded by some observers.

Portier, of New Orleans, La., only succeeded, however, in isolating *B. icteroides* in 3 out of 51 autopsies (*Journal of American Medical Association*, April 16, 1898), and, if we remember correctly, Veazie, of New Orleans, has recently reported that during the epidemic of 1899 in New Orleans a pure culture of *B. icteroides* was not isolated in any case of yellow fever.

Lutz (*Revista d'Igiene e Sanita Publica*, xi, No. 13, July, 1900, pp. 474-475) says as the result of his extensive observations on yellow fever that *Bacillus icteroides* cannot be found by present laboratory methods in more than half of the cases of yellow fever, and that when present, the colonies are few in number. It is possible that our future autopsies may give more favorable results as regards *B. icteroides*.

II.

The Mosquito as the Host of the Parasite of Yellow Fever.

—Having failed to isolate *B. icteroides*, either from the blood during life, or from the blood and organs of cadavers, two courses of procedure in our further investigations appeared to be deserving of attention, viz., first, a careful study of the intestinal flora in yellow fever in comparison with the bacteria that we might isolate from the intestinal canal of healthy individuals, in this vicinity, or of those sick with other diseases; or, secondly, to give our attention to the theory of the propagation of yellow fever by means of the mosquito—a

TABLE II.

NO. OF CASE.	DAY OF DISEASE.	TIME OF AUTOPSY.	SOURCE OF CULTURE.	B. ICTEROIDES.
1	Seventh.	2 hours after death.	Blood, liver, spleen, kidney.	Negative.
2	Sixth.	13 hours after death.	Blood, liver, spleen, kidney.	"
3	Fourth.	8 hours after death.	Blood, liver, spleen, kidney.	"
4	Eighth.	2 hours after death.	Abdominal cavity, blood, liver, spleen, kidney, bile, duodenum.	"
5	Fourth.	4 hours after death.	Blood, liver, spleen, kidney, bile, duodenum.	"
6	Sixth.	6½ hours after death.	Abdominal cavity, blood, pericardial fluid, lung, spleen, kidney, liver, bile, duodenum.	"

10	Fifth.	7 hours after death.	Liver, kidney, spleen, small intestine.	"
11	Third.	½ hour after death.	Liver, kidney, spleen.	"

Our failure to isolate *B. icteroides* in these 11 autopsies of yellow-fever patients was a result which we had not anticipated. One of us (Agramonte), who, at Santiago, Cuba, during the epidemic of 1898, succeeded in finding *B. icteroides* in 33% of his autopsies, has been

theory first advanced and ingeniously discussed by Dr. Carlos J. Finlay, of Havana, in 1881 (*Anales de la Real Academia*, vol. xviii, 1881, pp. 147-169).

We were influenced to take up the second line of investigation by reason of the well-known facts connected with the epidemiology of this disease, and, of course, by the brilliant work of Ross and the Italian observers, in connection with the theory of the propagation of malaria by the mosquito.

³ Cultures from the blood during life had been taken by Dr. Lazear in 3 other cases of yellow fever, but, owing to the death of our colleague, the necessary data as to the day of the disease on which cultures had been taken cannot be ascertained. These cultures were negative as regards the finding of Sanarelli's bacillus.

We were also very much impressed by the valuable observations made at Orwood and Taylor, Miss., during the year 1898, by Surgeon Henry R. Carter, U. S. Marine-Hospital Service (*A note on the interval between infecting and secondary cases of yellow fever, etc.*, Reprint from *New Orleans Medical Journal*, May, 1890). We do not believe that sufficient importance has been accorded these painstaking and valuable data. We observe that the members of the yellow fever commission of the Liverpool School of Tropical Medicine, Drs. Durham and Meyers, to whom we had the pleasure of submitting Carter's observations, have been equally impressed by their importance (*British Medical Journal*, September 8, 1900, pp. 656-7).

to us to the presence of an intermediate host, such as the mosquito, which having taken the parasite into its stomach, soon after the entrance of the patient into the noninfected house, was able after a certain interval to reconvey the infecting agent to other individuals, thereby converting a noninfected house into an "infected" house. This interval would appear to be from 9 to 16 days (allowing for the period of incubation), which agrees fairly closely with the time required for the passage of the malarial parasite from the stomach of the mosquito to its salivary glands.

In view of the foregoing observations we concluded to test the theory of Finlay on human beings. According to this author's observation of numerous inocu-

The circumstances under which Carter worked were favorable for recording with considerable accuracy the interval between the time of arrival of infecting cases in isolated farmhouses and the occurrence of secondary cases in these houses. According to Carter, "the period from the first (infecting) case to the first group of cases infected, at these houses, is generally from two to three weeks."

The houses having now become infected, susceptible individuals thereafter visiting the houses for a few hours, fall sick with the disease in the usual period of incubation, 1 to 7 days.

Other observations made by us since our arrival confirmed Carter's conclusions, thus pointing as it seemed

to us to the presence of an intermediate host, such as the mosquito, which having taken the parasite into its stomach, soon after the entrance of the patient into the noninfected house, was able after a certain interval to reconvey the infecting agent to other individuals, thereby converting a noninfected house into an "infected" house. This interval would appear to be from 9 to 16 days (allowing for the period of incubation), which agrees fairly closely with the time required for the passage of the malarial parasite from the stomach of the mosquito to its salivary glands.

In view of the foregoing observations we concluded to test the theory of Finlay on human beings. According to this author's observation of numerous inocu-

been allowed to slightly evaporate; so that these ova were at the time of our visit entirely above contact with the water. Notwithstanding this long interval after deposition, they were promptly converted into the larval stage, after a short period, by raising the level of the water in the basin.

With the mosquitos thus obtained we have been able to conduct our experiments. Specimens of this mosquito forwarded to Mr. L. A. Howard, Entomologist, Department of Agriculture, Washington, D. C., were kindly identified as *Culex fasciatus*, Fabr.

In this preliminary note we have not space to refer, at length, to the various interesting and valuable contributions made by Finlay to the mosquito theory for the propagation of yellow fever. In addition to the paper already quoted, his most valuable contributions

by the author of this theory, we believe that he has not, as yet, succeeded in reproducing a well-marked attack of yellow fever, within the usual period of incubation of the disease, attended by albumin and jaundice, and in which all other sources of infection could be excluded.

The experiments made by us on 11 nonimmune individuals are embraced in the preceding table (III), which should be carefully studied. The mosquito used in all cases was *Culex fasciatus* Fabr.

It will be seen that we record 9 negative and 2 positive results. It is, we think, important to observe that of the 9 failures to infect, the time elapsing between the biting of the mosquito and the inoculation of the healthy subject varied in 7 cases from 2 to 8 days (Nos. 1, 2, 3, 5, 7, and 9) and in the remaining 2 from 10 to 13 days (Nos. 6 and 9).

Chart I. Yellow fever following, within the usual period of incubation, the bite of an infected mosquito (*Culex fasciatus*).

to this important theory are to be found in the articles designated as follows:

Estadística de las Inoculaciones con mosquitos contaminados, etc., Reprint, Havana, 1891; *Fiebre Amarilla, Estudio Clínico Patológico y Etiológico*, Reprint, Havana, 1895; and *Yellow Fever Immunity—Modes of Propagation—Mosquito Theory*, 8th Congress of International Hygiene and Demography, Budapest, 1894.

His present views on this subject may be stated in his own language:

“First, reproduction of the disease, in a mild form, within 5 to 25 days after having applied contaminated mosquitos to susceptible subjects. Second, partial or complete immunity against yellow fever obtained even when no pathogenous manifestation had followed these inoculations.” (*Medical Record*, Vol. 55, No. 21, May 27, 1899.)

Without reviewing the cases regarded as mild forms

Five individuals out of the nine who failed to show any result (Nos. 2, 3, 4, 5 and 6) were inoculated by mosquitos that had bitten very mild cases of yellow fever on the fifth day of the disease, and one individual by a mosquito that had bitten a mild case of yellow fever on the seventh day of the disease. (This latter patient was discharged from the hospital three days later.) To this fact may possibly be attributed the negative results. Of the remaining three negative cases (Nos. 7, 8 and 9) and which had been inoculated by mosquitos that had bitten severe cases of the disease, the interval between the bite and the inoculation varied from 2 to 6 days.

In the two cases (Nos. 6 and 8) where the interval was respectively 10 and 13 days, the inoculations had been made with mosquitos that had bitten very mild cases of yellow fever on the fifth day of the attack. No.

8 was also bitten by a mosquito which had been infected by a severe case of yellow fever 3 days before.

We refrain from commenting further at this time upon the 9 negative cases, preferring to record the results obtained rather than to indulge in speculation.

Of the 2 cases which we have recorded as positive in Table III, we now propose to speak at greater length.

CASE 10.—Dr. James Carroll, Acting Assistant Surgeon U. S. Army, a member of this board, was bitten at 2 P.M. August 27, 1900, by *Culex fasciatus*. This particular mosquito has bitten a severe case of yellow fever on the second day of the disease 12 days before; a mild case of yellow fever, on the first day of the attack, 6 days preceding; a severe case of yellow fever, on the second day of the attack 4 days before and a mild case of yellow fever, on the second day of the attack 2 days before inoculation.

Dr. Carroll remained well until the afternoon of the 29th, when he states that he felt tired and for this reason, when on a visit to Las Animas Hospital the same afternoon (29th) some time between 4 and 6 P.M., after visiting a few patients, he left the wards and waited outside on the porch, while his companions remained in the wards.

August 30. During the afternoon, although not feeling well, Dr. Carroll visited La Playa, about one and a half miles from Columbia Barracks, and took a sea-bath.

August 31. A.M. Dr. Carroll realized that he was sick and that he had fever, although he refrained from taking his temperature, but did visit the laboratory, distant about 140 yards, for the purpose of examining his blood for the malarial parasite. The examination was negative. During the afternoon he was compelled to take to his bed. At 7 P.M. temperature was 102° F. He had no headache or backache; only a sense of great lassitude. His eyes were injected and his face suffused.

September 1. At 7 A.M. his temperature was 102°. Blood was again carefully examined by Dr. Lazear with negative result. At 11 A.M. temperature was 102°.

The case having been diagnosed as one of yellow fever, Dr. Carroll was at noon removed to the yellow fever wards. At 9 P.M. temperature was 102.8°, pulse 90; at 12 o'clock midnight temperature 103.4°, pulse 84.

On September 2, at 3 A.M., temperature was 103.6°, pulse 80. A trace of albumin was not found in the urine. The subsequent history of the case was one of severe yellow fever. Jaundice appeared on September 3.

The accompanying chart, No. 1, contains all of the necessary data.

The question of diagnosis having been clearly and easily established, it now becomes important to follow Dr. Carroll's movements for a period of ten days preceding the mosquito inoculation, and during the period elapsing from the bite of the insect until the commencement of the attack.

On August 21, 22 and 23, Dr. Carroll was at Columbia Barracks, outside of the epidemic zone. On August 24th he visited the autopsy-room of Military Hospital, No. 1, which is situated on Principe hill overlooking the city of Havana. He was present in the autopsy-room while an autopsy was made by Dr. Agramonte on a case of pernicious malarial fever. Dr. Carroll only took cultures from the blood and organs as the section proceeded. He was there about half an hour, and then returned to Columbia Barracks. Subsequent microscopic study of sections of the liver and spleen showed that the case autopsied on the 29th was really a case of pernicious malarial fever.

It should be stated that although cases of yellow fever are not admitted to Military Hospital No. 1, an English sea-captain had been admitted to its wards a few days before, whose case developed into one of yellow fever with fatal results, and autopsy had been held upon the body by Dr. Agramonte in this death room on the day preceding Dr. Carroll's visit to it. According to Dr. Carroll, the room was by no means in a cleanly condition. As Dr. Carroll's visit to this room was made on August 24, and as he began to complain on August 29, about the average period of incubation of yellow fever, there is a possible chance for infection in this way. We must call attention, however, to the fact that Dr. Agramonte, whenever he performs an autopsy in this room, is always attended by a young soldier of the Hospital Corps, U. S. Army, who is detailed for that purpose, and whose

duty it is to assist and afterwards to tend to the cleaning of the autopsy table. This soldier, a nonimmune American, was present when Dr. Carroll was there, and remained afterward to attend to his duties. He has not contracted yellow fever by his duties in this room from day to day. Our own experience would seem to accord with others, viz., that attendance upon autopsies and the handling of portions of organs of yellow-fever cases removed to the laboratory is unattended with danger. Certainly the three nonimmune members of this board, up to the time of these mosquito inoculations had, during the past three months, come in close contact with the dead bodies and organs of yellow-fever cases, freely handling and examining these organs, including the small intestine, even kept at thermostat temperature for 24 hours, without contracting the disease. We have, of course, never neglected to cleanse our hands with disinfectants.

Dr. Carroll, upon his visit to the before-mentioned dead-room, only used the platinum loop for taking cultures, and did not come in contact with the autopsy table.

The only other opportunity for infection in his case would appear to have been during his visit to Las Animas Hospital, situated in the suburbs of Havana, as yellow-fever patients are admitted in large numbers. We have already pointed out that Dr. Carroll was complaining of lassitude at the hour of his visit, which was about 50 hours after his inoculation with the contaminated mosquito. We have also called attention to the fact that he remained, for the greater part of his visit, outside of the hospital, on the piazza. This would appear to cast doubt upon his visit to Las Animas as the source of his infection.

We do not wish to be understood as unnecessarily seeking to lay too much emphasis upon the exclusion in this case of other sources of infection than the mosquito, as we fully appreciate that Dr. Carroll had been on two occasions within the epidemic zone during the week preceding his attack of yellow fever. His movements on these occasions we have already given.

We will again refer to Dr. Carroll's case, after we have given the history of Case No. 11, which we have designated as our second positive result.

CASE 11.—X. Y., aged 24, white, American, a resident of the military reservation of Columbia barracks, was bitten during the forenoon of August 31, 1900, by the same mosquito that had bitten Case 10 (Dr. Carroll) four days before, and which in the meantime had bitten a mild case of yellow fever (first day) two days before being applied to X. Y.

X. Y. was also bitten by a second mosquito that had been applied to a fatal case of yellow fever (second day) 12 days before; and to two mild cases (second day) 4 and 10 days previously; also, by a third mosquito that had bitten a fatal case of yellow fever (second day) 12 days before; a severe case (first day) 2 days before, and three mild cases (first, second, and second day) 4, 6, and 10 days before; finally by a fourth mosquito that had bitten three severe cases of yellow fever (all on first day) 2, 4, and 8 days previously, and one mild case (second day) 6 days before. (Vide Table III)

It will be seen that X. Y. was bitten by four mosquitos, two of which had bitten severe (fatal) cases of yellow fever 12 days previously; one of which had bitten a severe case (second day) 16 days before and one which had bitten a severe case 8 days before.

X. Y. began to experience a sense of dizziness and disinclination to work. This was just five days from the time of the mosquito inoculation; 24 hours later he was still dizzy and light-headed in attempting to move about. During the afternoon (sixth day after inoculation), he had chilly sensations, followed by fever and restlessness during the night.

On the following day (seventh day after inoculation) 8 A.M., temperature was 102.8° F., his eyes were slightly injected, and his face suffused. The patient was removed to the yellow fever wards; at 9 A.M., temperature was 103° F., pulse 66. A trace of albumin was found in the urine during the afternoon (third day of the attack). This increased during the following days. The conjunctivæ were slightly jaundiced on the fourth day of the disease, which was more distinct and could be plainly seen on the anterior aspect of the chest on the fifth and following days. Bleeding from the gums was noticed on the third and subsequent days after admission. Repeated examinations of the blood failed to show any malarial parasites.

The course of the fever, the appearance of albumin in the urine, with jaundice and hemorrhage from the gums, together with the slow pulse, all pointed distinctly to the diagnosis of yellow fever. His attending physician, Dr. Roger P. Ames, U. S. A., an expert in the diagnosis and treatment of this disease, did not hesitate to diagnose X. Y.'s attack as one of "well pronounced yellow fever." Dr. Ames was not cognizant of the method of inoculation in this case. (Vide Chart II).

from May, 1900, the average monthly population of this station, including civilian employes, has been 1,400, nearly all of whom are young nonimmunes.

There have occurred amongst this nonimmune population from May 1 to October 13, 1900, 16 cases of yellow fever, all of which have been easily and readily traced to a visit to within the boundaries of the epidemic zone, except cases 10 and 11 of Table III., and one other case of which we shall presently speak. These cases have been distributed as follows:

Chart II. Yellow fever following, within the usual period of incubation, the bite of an infected mosquito (*Culex fasciatus*).

The diagnosis, therefore, not being in doubt, we must follow this patient's movement's during the 10 days preceding the bite of the mosquitos and from this time until 5 days later, when the attack began. It so happens that we can follow X. Y.'s movements for a much longer period. Fifty-seven days prior to his inoculation, he spent a day and night in the City of Havana; 16 days before the inoculation, he rode on horseback with 6 other nonimmunes a distance of about 1½ miles towards the seashore and returned to his dwelling, without in the meantime dismounting from his horse. From this time until his complete convalescence was established, he had remained within the immediate vicinity of his home. So that it may be positively stated that X. Y. had not absented himself from the Military Reservation of Columbia Barracks during a period of 57 days prior to his inoculation (with the exception above stated) nor between the date of his inoculation and the establishment of convalescence.

Let us now inquire whether the military reservation of Columbia Barracks is outside of the epidemic zone of yellow fever. To this we answer that since the commencement of the present epidemic of yellow fever in Havana, dating

May 24.....	1	July 29th	1

“ 29th.....	1	September 7.....	1
July 9th	1	“ 19.....	1
“ 26th.....	1		
		Total,	16 cases.

Ten of these cases have occurred amongst an average monthly military population of 1,295 men and six cases in an average civilian population of 105. Whenever these cases have occurred, as soon as the patient has been removed to hospital, most careful measures of disinfection have been immediately carried out by a trained sanitary squad, under the personal supervision of a medical officer. These measures have consisted of destruction by fire of mattresses, the disinfection of bedding and clothing with 1 to 500 bichlorid solution, and the application of the same solution freely to the ceiling, walls, and floors, by means of a force pump.

We repeat that no case has ever been connected with a

preceding case, but that the source of infection has been readily shown to have occurred during the individual's visit to Havana, 6 miles distant, or to some other nearer Cuban settlement.

We now invite attention to the fact that from August 17 to October 13, a period of 57 days, only 3 cases of yellow fever have occurred amongst this population of 1,400 nonimmune Americans, and we consider it very important to note that 2 of these had been bitten within 5 days of the commencement of their attacks, by contaminated mosquitos.

Taken in connection with Case 11, in which we have been unable to find any other source of infection than the bite of an infected mosquito, five days preceding the attack, the case of Dr. Carroll (Case 10, Table III) becomes strongly confirmatory of the same origin.

We will now briefly give the history of the third case of yellow fever that has occurred at Columbia Barracks during the period August 17 to October 13, 1900.

In the light of Cases 10 and 11, we consider this case of sufficient importance to be here included, especially as it is one that might be possibly designated as a case of accidental infection by a mosquito.

CASE 3.—Dr. Jesse W. Lazear, Acting Assistant-Surgeon, U. S. Army, a member of this board, was bitten on August 16, 1900 (Case 3, Table III) by a mosquito (*Culex fasciatus*) which 10 days previously had been contaminated by biting a very mild case of yellow-fever (fifth day). No appreciable disturbance of health followed this inoculation.

On September 13 1900 (forenoon), Dr. Lazear, while on a visit to Las Animas Hospital, and while collecting blood from yellow-fever patients for study, was bitten by a *Culex* mosquito (variety undetermined). As Dr. Lazear had been previously bitten by a contaminated insect without after-effects, he deliberately allowed this particular mosquito, which had settled on the back of his hand, to remain until it had satisfied its hunger.

On the evening of September 18, 5 days after the bite, Dr. Lazear complained of feeling "out of sorts," and had a chill at 8 P.M.

On September 19, 12 o'clock noon, his temperature was 102.1°, pulse 112; his eyes were injected and his face suffused; at 3 P.M. temperature was 103.4°, pulse 104; 6 P.M., temperature 103.8° and pulse 106; albumin appeared in the urine. Jaundice appeared on the third day. The subsequent history of this case was one of progressive and fatal yellow fever, the death of our much-lamented colleague having occurred on the evening of September 25, 1900.

As Dr. Lazear was bitten by a mosquito while present in the wards of a yellow-fever hospital, one must, at least, admit the possibility of this insect's contamination by a previous bite of a yellow-fever patient. This case of accidental infection therefore cannot fail to be of interest taken in connection with Cases 10 and 11.

For ourselves, we have been profoundly impressed with the mode of infection and with the results that followed the bite of the mosquito in these three cases. Our results would appear to throw new light on Carter's observations in Mississippi, as to the period required between the introduction of the first (infecting) case and the occurrence of secondary cases of yellow fever.

Since we here, for the first time, record a case in which a typical attack of yellow fever has followed the bite of an infected mosquito, within the usual period of incubation of the disease, and in which other sources of infection can be excluded, we feel confident that the publication of these observations must excite renewed interest in the mosquito-theory of the propagation of yellow fever, as first proposed by Finlay.

From the first part of our study of yellow fever, we draw the following conclusions:

1. The blood taken during life from the general ven-

ous circulation, on various days of the disease, in 18 cases of yellow fever, successively studied, has given negative results as regards the presence of *B. icteroides*.

2. Cultures taken from the blood and organs of 11 yellow-fever cadavers have also proved negative as regards the presence of this bacillus.

3. *Bacillus icteroides* (Sanarelli) stands in no causative relation to yellow fever, but, when present, should be considered as a secondary invader in this disease.

From the second part of our study of yellow fever, we draw the following conclusion:

The mosquito serves as the intermediate host for the parasite of yellow fever, and it is highly probable that the disease is only propagated through the bite of this insect.

RESTITUTION OF THE CONTINUITY OF THE TIBIA BY TRANSPLANTATION OF THE PATELLA INTO AN EXTENSIVE OSTEOMYELITIC DEFECT.

By N. SENN, M.D., PH.D., LL.D.,
of Chicago.

Professor of Surgery, Rush Medical College.

THE restoration of the continuity of any of the large long bones of the body after extensive permanent traumatic or pathologic defects always presents great and sometimes insurmountable difficulties. The absence of osteogenetic tissue resulting from injury or disease explains very satisfactorily the defective callus formation and its inevitable result—nonunion. The two tissue elements which take the most important part in the production of callus are the osteoblasts of the periosteum and the myeloblasts of the medullary tissue. Delayed union and nonunion are therefore most liable to occur in cases in which the periosteum and myeloid tissue have been extensively destroyed by injury or disease, and in persons in whom the bone-producing cells which they contain are defective in number, or lack the necessary degree of reproductive power. The vegetative capacity of the tissues is not infrequently taxed to its utmost in the repair of simple fractures and limited osteomyelitic defects, and in extensive traumatic and pathologic defects it often falls short in restoring the continuity of the bone. It is in such instances that implantation of bone from the lower animals has been attempted, and for which the most complicated autoplasmic operations have been devised and practised. The former procedure has been studied experimentally on a very large scale, the result of which, as well as a large clinical material which has accumulated, combine to demonstrate its utter uselessness in effecting bone-repair in man. Such operations have invariably proved a failure. Experimental research has established the fact that in the lower animals the transplantation of bone from one species to another is uniformly followed by a similar negative result. The transplantation of small pieces of bone from one human being to another has been performed repeatedly with success, but such opportunities are seldom presented, so that the surgeon has usually to rely on autotransplantation in furnishing the material for the repair of large bone-defects. In limited defects of the long bones the space between the fragments can be filled in with chips of bone removed with chisel and hammer from the surface of the bone-ends which are implanted into the gutter between the vivified fragments. I have performed this operation in a number of cases with signal success. In the technic of the operation it is

important to preserve the periosteal envelope with the most pedantic care, and this is utilized as a covering for the implanted bone-grafts over which it is sutured with buried absorbable suture-material. If the wound remains aseptic, every one of the grafts will retain its vitality and take an active part in the subsequent process of repair. In the treatment of extensive defects it becomes necessary to transplant larger pieces of bone with vascular connections; hence the material must be taken from a place sufficiently near the seat of implantation to insure an adequate blood-supply. The case reported here serves to illustrate in a most convincing manner the nonfeasibility of resorting to implantation of bone from the lower animals in the repair of bone-defects in the human being, as well as the value of autotransplantation of large pieces of bone with preservation of their vascular connections. It is a case in which undoubtedly the patella was utilized, for the first time, in the restoration of a large osteomyelitic defect of the tibia.

Restitution of the Continuity of the Tibia by Implantation of the Patella into an Extensive Osteomyelitic Defect.—The patient, a Chicago newsboy, 11 years of age, free from any hereditary tendencies to disease, when in his usual health and without any premonitory symptoms, was taken suddenly ill July 20, 1893. The violent febrile disturbance which characterized the disease for the first few days was diagnosed and treated as typhoid fever, as the local affection was entirely overshadowed by the general symptoms. In a few days a rapidly increasing swelling made its appearance which involved the upper part of the left leg and the adjacent knee-joint. Ten days from the beginning of the attack a large abscess formed below the knee-joint and over the inner aspect of the tibia, which was incised and drained by the family physician. The evacuation of a large quantity of thin, sanious pus had little or no influence in abating the septic condition, so that on July 30 the patient was sent to the Presbyterian Hospital with the expectation that an amputation of the thigh would be performed in an attempt to ward off a speedy fatal termination from sepsis. When the patient came under my care at that time as a clinical patient he presented all the symptoms of progressive sepsis. The tongue was brown and dry, pulse 120 to 140, and the temperature ranged from 102° to 104° F. A low muttering delirium, profuse sweating, and a marked abdominal tympanites completed the picture of profound septic intoxication. The swelling now involved the entire leg; the skin over the upper part of the leg over the tibia was red and very edematous, the knee-joint enormously distended, and edema extended over the greater portion of the thigh. It was very evident from the general and local symptoms that the patient was the subject of a diffuse osteomyelitis of the tibia complicated by suppurative inflammation of the knee-joint and that limb and life were in imminent danger from septopyemia. I decided to make an attempt to save the limb and guard against fatal sepsis by removal of the shaft of the tibia and free incision and drainage of the knee-joint. The operation was performed in the clinic of Rush Medical College the day after his admission into the hospital, July 31. The patient was anesthetized and an incision was made over the crest of the tibia from the upper to the lower epiphysis. The shaft of the tibia was found denuded of periosteum and beginning epiphyseolysis at both ends. The entire shaft of the bone was removed, the limb immobilized

in a suspension splint, and the large wound was freely drained and subjected to frequent antiseptic irrigations without disturbing the fixation-dressing. Thorough drainage of the knee-joint was established by the insertion of two large tubular drains, one transversely, the other in an anteroposterior direction. The operation was followed promptly by a decided improvement in the general condition of the patient. Although this energetic treatment proved successful in limiting the progressive infection, suppuration continued profusely for weeks, and the temperature at irregular intervals occasionally reached 102° F. During this time no appreciable indications of repair were discernible. In March of the following year a subacute osteomyelitis made its appearance very insidiously in the right humerus near the upper epiphysis which terminated in abscess-formation. The abscess was incised and drained and later a small sequestrum was removed. After this

FIG. 2.—Lower fragment impacted into the upper border of the patella. Wound sutured.

the patient's general health commenced to improve very slowly and suppuration of the operative wound over the osteomyelitic defect gradually diminished, but callus formation failed to take place. Owing to the absence of the shaft of the tibia, the upper articular end of the fibula gradually became displaced, at least an inch, in an upward direction. During the year 1895 limited bone-production from the epiphyseal extremities became noticeable, and as suppuration had become reduced to a minimum, and the general condition of the patient seemed to warrant operative intervention for the purpose of restoring the continuity of the tibia, implantation of the tibia of a young rabbit was resorted to on two occasions with an interval of about six months. Both operations were performed in a similar manner under the influence of a general anesthetic. In the first operation, after clearing the frag-

ments on each side, the space between them was found to measure at least five inches. The fragments were tapered, the ends not larger than a goosequill. (Fig. 1.) The articular surfaces of the tibia of the rabbit were removed and the bone implanted between the fragments. Both operations proved a complete failure. After the first operation the implanted bone was eliminated spontaneously after three weeks. The wound

after the second operation healed, with the exception of a small fistula which was enlarged ten weeks later, and the implanted bone, which had become partly absorbed, was removed. The knee-joint in the meantime had become ankylosed, and I decided to utilize the patella, which had become functionally useless, in restoring the continuity of the bone.

After clearing out the infected granulations between

the fragments with a sharp spoon, and making thorough disinfection of the wound, the gutter for the reception of the patella was deepened by a vertical incision. The patella and its ligament with the overlying skin were included in a horseshoe-shaped incision with the concavity directed downward, and the flap including the patella was transplanted into the gap between the two fragments in such a manner that the upper border of the patella was brought in contact with the lower frag-

ment (Fig. 2). It was found that the patella was not long enough to span the gap, hence the upper border was perforated with a drill and the lower fragment was impacted into the perforation, which left a space between the lower border of the patella and the upper fragment. (Fig. 3.) The wound healed faultlessly, largely by primary intention. This operation was performed March 31, 1896. The patella united with the lower fragment by bony union. A few months later the patella was exposed by a vertical incision, divided obliquely, and the upper fragment was mobilized sufficiently to be brought in contact with the upper end of the tibia, which was impacted into a perforation made with a drill. (Fig. 4.) The patellar fragments were united by two strong catgut-sutures (Fig. 4), and the external incision sutured without making any provision for drainage. This wound again healed slowly by primary intention, and the transplanted upper patellar fragment became a part of the upper fragment, but

a pseudoarthrosis formed between the patellar fragments. On May 20, 1898, the pseudoarthrosis was exposed by a vertical incision, the fibrous union was excised, and the vivified surfaces united by silver-wire suture. The wound healed with the exception of a fistulous opening which led down to the silver-wire suture, which was removed in July, 1898, after which the wound closed. A number of weeks later the x-ray demonstrated bony union between the patellar and tibial fragments. (Fig. 5.)

A photograph of the limb taken recently (Fig. 6) shows that it is in a useful position. The patient walks about with the aid of a cane, and there is every prospect that he can soon dispense with this mechanical support. As has been stated before, this case demonstrates most conclusively that we cannot rely on transplantation of bone from any of the lower animals in the restoration of bone-defects, on the one hand, as well as the value of autotransplantation on the other.

THE INTERRELATIONSHIP BETWEEN CARDIOVASCULAR DISEASE AND RENAL DISEASE, WITH PARTICULAR REFERENCE TO THE DIAGNOSIS AND TREATMENT.*

By ALOYSIUS O. J. KELLY, A.M., M.D.,
of Philadelphia.

Instructor in Clinical Medicine, University of Pennsylvania; Assistant Physician to the University Hospital; Visiting Physician to St. Mary's and St. Agnes' Hospitals, etc.

THAT disease of the cardiovascular system and disease of the kidneys are frequently concomitant conditions in the same individual has long been recognized; that the one is sometimes the forerunner of the other and vice versa is also well established. On the other hand, that this mutual interrelationship is sometimes overlooked when it exists; that, in the event of widespread disease, disorder of one organ only—the heart, the kidneys, or the bloodvessels, as the case may be—is detected; and that the primary affection often remains undetermined, are equally certain. These latter facts, as also the circumstance that it has lately been my fortune to have observed a number of cases illustrating the mutual relationship in disease between the kidneys and the cardiovascular system, serve as motive for my remarks.

That the diagnosis of chronic nephritis—I refer particularly to chronic interstitial nephritis or cirrhosis of the kidney—is a matter of extreme importance cannot be gainsaid. Such, however, are the protean and varying manifestations of the disease, and such is the insidiousness of its course, that it may remain for years entirely unsuspected. Indeed, in the majority of cases, the early stage of the affection are altogether overlooked, unless it be discovered accidentally by the routine examination of the urine, as, for instance, for life insurance, or for patients ill with other diseases. When finally after a number of years it does produce symptoms sufficiently obtrusive to attract the attention of the patient or his physician, these are of such a nature that they are likely, for a time at least, to be attributed to disorder of some organ other than the kidneys. Thus, while the patient may present himself with the idea that he is suffering with diabetes on account of the large quantity of urine that he voids, he is just as likely to complain of dimness of vision, the consequence of albuminuric retinitis; of one of the many manifestations of uremia, such as dyspnea or asthma; of gastrointestinal derangements, such as gastric catarrh, gastric ulcer (that is, copious hematemesis, of which I have recently observed an interesting instance), or diarrhea; or of headache, hemicrania, tinnitus aurium, or vertigo; of neurasthenia, pains in the muscles or joints, or eczema; of palpitation of the heart and precordial distress; or the patient, in apparent good health, may suddenly develop a severe and even fatal attack of cardiac failure, pass into uremic coma or convulsions, or he may suffer an apoplexy and die. It is thus apparent that only careful inquiry and patient investigation will enable one to establish the correct diagnosis in some cases. All factors that assist in the consummation of this end, therefore, must be utilized to their fullest extent.

In the first place must be mentioned the careful, systematic, and painstaking examination of the urine, and hardly in the second place, because it is not less import-

ant, the careful investigation of the cardiovascular apparatus. The examination of the urine must include not only the examination for the presence of albumin, which is of the greatest importance, but also the careful determination of the specific gravity, the total daily quantity of urine voided, the total daily excretion of solids, and a microscopic examination. The latter must not be omitted even if the chemic tests fail to reveal the presence of albumin, for casts may be present without albumin, and the latter may be absent from some specimens of the urine and present in others. It may be absent for days, weeks, or months at a time; it may be missed in the early morning urine and present in that voided later in the day; and it may be present only after exercise, emotional or other excitement, or after eating. But of the common concomitants of chronic interstitial nephritis and such as may serve for diagnosis even in the absence of positive indications on the part of the urine, are those referable to the cardiovascular apparatus. It may be said that from the very inception of the disease, the heart and bloodvessels, in response, shall it be allowed, to excessive functional demands, suffer more or less; they reveal more or less deviation from the normal. These alterations are continuously present and may be recognized whether or not the urine reveals the presence of albumin and casts. Their diagnostic importance, therefore, cannot be overestimated; their importance from a prognostic and therapeutic standpoint will appear later.

The lesions of the heart characteristic of chronic interstitial nephritis involve the muscle and find their expression in hypertrophy. With this there is at times associated some interstitial myocarditis with increase of the intermuscular fibrous trabeculae, especially in the neighborhood of small obliterated coronary arterioles. In some instances, especially late in the disease, fatty degeneration of the heart-muscle also may be detected. Valvular lesions are extremely uncommon. Those that are found in association with renal disease are either an antecedent condition (of which mention will be made later), or they are the consequence purely of mechanic causes—the result of dilation of the cavities of the heart. The lesion in these cases is one of relative insufficiency, the valve leaflets, in themselves normal, being incapable of closing the abnormally enlarged orifices. The mechanic consequences of this defect, however, are similar to those produced by valvular lesions due to endocarditis.
